17.2.4.3 The maximum edge distance to the nearest line of fasteners from an edge of any un-stiffened part should not exceed 12 $t\varepsilon$, where $\varepsilon = (250/f_y)^{1/2}$ and t is the thickness of the thinner outer plate. This would not apply to fasteners interconnecting the components of back to back tension members. Where the members are exposed to corrosive influences, the maximum edge distance shall not exceed 40 mm plus $4t$, where t is the thickness of thinner connected plate.

17.2.5 *Tacking Fasteners*

17.2.5.1 In case of members covered under **17.2.4.3**, when the maximum distance between centres of two adjacent fasteners as specified in **17.2.4.3** is exceeded, tacking fasteners not subjected to calculated stress shall be used.

17.2.5.2 Tacking fasteners shall have spacing in a line not exceeding 32 times the thickness of the thinner outside plate or 300 mm, whichever is less. Where the plates are exposed to the weather, the spacing in line shall not exceed 16 times the thickness of the thinner outside plate or 200 mm, whichever is less. In both cases, the distance between the lines of fasteners shall not be greater than the respective pitches.

17.2.5.3 All the requirements specified in **17.2.5.2** shall generally apply to compression members, subject to the stipulations given under **14** affecting the design and construction of compression members.

17.2.5.4 In tension members [*see* **13**] composed of two flats, angles, channels or tees in contact back to back or separated back to back by a distance not exceeding the aggregate thickness of the connected parts, tacking fasteners with solid distance pieces shall be provided at a spacing in line not exceeding 1 000 mm.

17.2.5.5 For compression members covered under **14**, tacking fasteners in a line shall be spaced at a distance not exceeding 600 mm.

17.2.6 *Countersunk Heads*

For countersunk heads, one-half of the depth of the countersinking shall be neglected in calculating the length of the fastener in bearing in accordance with **17.3.3**. For fasteners in tension having countersunk heads, the tensile strength shall be reduced by 33.3 percent. No reduction is required to be made in shear strength calculations.

17.3 Bearing Type Bolts

17.3.1 *Effective Areas of Bolts*

17.3.1.1 Since threads can occur in the shear plane, the area A_e for resisting shear should normally be taken as the net tensile stress area, A_n of the bolts. For bolts where the net tensile stress area is not defined, A_n shall be taken as the area at the root of the threads.

17.3.1.2 Where it can be shown that the threads do not occur in the shear plane, A_e may be taken as the cross section area, A_s at the shank.

17.3.1.3 In the calculation of thread length, allowance should be made for tolerance and thread run off.

17.3.2 A bolt subjected to a factored shear force (V_{sb}) shall satisfy the condition

$$V_{sb} \leq V_{db}$$

where V_{db} is the design strength of the bolt, taken as the smaller of the value as governed by shear, V_{dsb} (*see* **17.3.3**) and bearing, V_{dpb} (*see* **17.3.4**).

17.3.3 *Shear Capacity of Bolt*

The design strength of the bolt, V_{dsb} as governed by shear strength is given by:

$$V_{dsb} = V_{nsb} / \gamma_{mb}$$

where

V_{nsb} = nominal shear capacity of a bolt, calculated as follows.

$$V_{nsb} = \frac{f_u}{\sqrt{3}} \left(n_n A_{nb} + n_s A_{sb} \right)$$

where

A_{nb} = net shear area of the bolt at threads, may be taken as the area corresponding to root diameter at the thread;

A_{sb} = nominal plain shank area of the bolt;

f_u = ultimate tensile strength of a bolt;

n_n = number of shear planes with threads intercepting the shear plane; and

n_s = number of shear planes without threads intercepting the shear plane.

17.3.3.1 *Long joints*

When the length of the joint, l_j of a splice or end connection in a compression or tension element containing more than two bolts (that is, the distance between the first and last rows of bolts in the joint, measured in the direction of the load transfer) exceeds 15d in the direction of load, the nominal shear capacity (*see* **17.3.2**), V_{db} shall be reduced by the factor β_{lj}, given by:

$$\beta_{lj} = 1.075 - l_j / (200\, d) \text{ but } 0.75 \leq \beta_{lj} \leq 1.0 = 1.075 - 0.005(l_j / d)$$

where

d = Nominal diameter of the fastener.

NOTE — This provision does not apply when the distribution of shear over the length of joint is uniform, as in the connection of web of a section to the flanges.

17.3.3.2 *Large grip lengths*

When the grip length, l_g (equal to the total thickness of the connected plates) exceeds 5 times the diameter, d of the bolts, the design shear capacity shall be reduced by a factor β_{lg}, given by:

$$\beta_{lg} = 8d / (3d + l_g) = 8 / (3 + l_g/d)$$

β_{lg} shall not be more than β_{lj} given in **17.3.3.1**. The grip length, l_g shall in no case be greater than 8d.

17.3.3.3 *Packing plates*

The design shear capacity of bolts carrying shear through a packing plate in excess of 6 mm shall be decreased by a factor, β_{pk} given by:

$$\beta_{pk} = (1 - 0.0125 t_{pk})$$

where

t_{pk} = thickness of the thicker packing, in mm.

17.3.4 *Bearing Capacity of the Bolt*

The design bearing strength of a bolt on any plate, V_{dpb} as governed by bearing is given by:

$$V_{dpb} = V_{npb} / \gamma_{mb}$$

where

V_{npb} = Nominal bearing strength of a bolt; and

= $2.5\, k_b\, d\, t\, f_u$.

where

d_0 = diameter of the hole;

d = nominal diameter of the bolt;

f_{ub}, f_u = Ultimate tensile stress of the bolt and the ultimate tensile stress of the plate, respectively;

e, p = end and pitch distances of the fastener along bearing direction;

k_b = is smaller of $\frac{e}{3d_0}$, $\frac{p}{3d_0} - 0.25$, $\frac{f_{ub}}{f_u}$, 1.0; and

t = summation of the thicknesses of the connected plates experiencing bearing stress in the same direction, or if the bolts are countersunk, the thickness of the plate minus one half of the depth of countersinking.

The bearing resistance (in the direction normal to the slots in slotted holes) of bolts in holes other than standard clearance holes may be reduced by multiplying the bearing resistance obtained as above, V_{npb}, by the factors given below:

a) Over size and short slotted holes – 0.7; and

b) Long slotted holes – 0.5.

NOTE — The block shear of the edge distance due to bearing force may be checked as given in 12.4.

17.3.5 *Tension Capacity*

A bolt subjected to a factored tensile force, T_b shall satisfy,

$$T_b \leq T_{db}$$

where

T_{db} = T_{nb} / γ_{mb}; and

T_{nb} = nominal tensile capacity of the bolt, calculated as.

$$T_{nb} = 0.90\, f_{ub} A_n < f_{yb} A_{sb} (\gamma_{mb} / \gamma_{m0})$$

where

A_{sb} = shank area of the bolt;

A_n = net tensile stress area as specified in the appropriate Indian Standard (for bolts where the tensile stress area is not defined, An shall be taken as the area at the bottom of the threads);

f_{ub} = ultimate tensile stress of the bolt; and

f_{yb} = yield stress of the bolt.

17.3.6 *Bolt Subjected to Combined Shear and Tension*

A bolt required to resist both design shear force (V_{sd}) and design tensile force (T_b) at the same time shall satisfy,

$$\left(\frac{V_{sb}}{V_{db}}\right)^2 + \left(\frac{T_b}{T_{db}}\right)^2 \leq 1.0$$

where

V_{db} = design shear capacity (*see* **17.3.2**);

V_{sb} = factored shear force acting on the bolt;

T_b = factored tensile force acting on the bolt, and

T_{db} = design tension capacity (*see* **17.3.5**).

17.4 Friction Grip Type Bolting

17.4.1 In friction grip type bolting, initial pretension in bolt (usually high strength) develops clamping force at the interfaces of elements being joined. The frictional resistance to slip between the plate surfaces subjected to clamping force opposes slip due to externally applied shear. Friction grip type bolts and nuts shall conform to the accepted standard [C-6A(39)]. Their installation procedures shall conform to good practice [C-6A(15)].

17.4.2 Where slip between bolted plates cannot be tolerated at working loads/ strength limit states loads (slip critical connections), the requirements of **17.4.3** shall be satisfied at service and strength limit states loads, respectively. However, the requirements of **17.4.4** shall be satisfied by all connections at the strength limit states.

17.4.3 *Slip Resistance*

Design for friction type bolting, where slip resistance is required at factored design force V_{sf}, shall satisfy the following:

$$V_{sf} \leq V_{dsf}$$

where

V_{dsf} = V_{nsf} / γ_{mf}; and

V_{nsf} = nominal shear capacity of a bolt as governed by slip for friction type connection, calculated as follows.

$$V_{nsf} = \mu_f n_e K_h F_o$$

where

A_{nb} = net area of the bolt at threads;

f_o = proof stress (= 0.70 f_{ub});

F_o = minimum bolt tension (proof load) at installation and may be taken as $A_{nb} f_o$;

K_h = 1.0 for fasteners in clearance holes;

= 0.85 for fasteners in oversized and short slotted holes and for fasteners in long slotted holes loaded perpendicular to the slot;

n_e = number of effective interfaces offering frictional resistance to slip;

μ_f = coefficient of friction (slip factor) as specified in Table 21 ($\mu_f \leq 0.55$);

= 0.7 for fasteners in long slotted holes loaded parallel to the slot;

γ_{mf} = 1.10 (if slip resistance is designed at service load); and

= 1.25 (if slip resistance is designed at ultimate load).

NOTE — V_{nsf} may be evaluated at a service load or ultimate load using appropriate partial safety factors, depending upon whether slip resistance is required at service load or ultimate load.

Table 21 Typical Average Values for Coefficient of Friction (μ_f)

(*Clause* 17.4.3)

Sl No. (1)	Treatment of Surface (2)	Coefficient of Friction, μ_f (3)
i)	Surfaces not treated	0.20
ii)	Surfaces blasted with short or grit with any loose rust removed, no pitting	0.50
iii)	Surfaces blasted with shot or grit and hot-dip galvanized	0.10
iv)	Surfaces blasted with shot or grit and spray-metallized with zinc (thickness 50 µm to 70 µm)	0.25
v)	Surfaces blasted with shot or grit and painted with ethyl zinc silicate coat (thickness 30 µm to 60 µm)	0.30
vi)	Sand blasted surface, after light rusting	0.52
vii)	Surfaces blasted with shot or grit and painted with ethyl zinc silicate coat (thickness 60 µm to 80 µm)	0.30
viii)	Surfaces blasted with shot or grit and painted with alkali zinc silicate coat (thickness 60 µm to 80 µm)	0.30
ix)	Surface blasted with shot or grit and spray metallized with aluminium (thickness > 50 µm)	0.50
x)	Clean mill scale	0.33
xi)	Sand blasted surface	0.48
xii)	Red lead painted surface	0.1

17.4.3.1 *Long Joints*

The provision for the long joints in **17.3.3.1** shall apply to friction grip connections also.

17.4.4 *Capacity after Slipping*

When friction type bolts are designed not to slip only under service loads, the design capacity at ultimate load may be calculated as per bearing type connection (*see* **17.3.2** and **17.3.3**).

NOTE — The block shear resistance of the edge distance due to bearing force may be checked as given in **13.4**.

17.4.5 *Tension Resistance*

A friction bolt subjected to a factored tension force (T_f) shall satisfy:

$$T_f \leq T_{df}$$

where

$T_{df} = T_{nf} / \gamma_{mf}$

T_{nf} = nominal tensile strength of the friction bolt, calculated as:

$$T_{nf} = 0.9\, f_{ub}\, A_n \leq f_{yb}\, A_{sb} (\gamma_{m1} / \gamma_{m0})$$

where

A_n = net tensile stress area as specified in various parts of the accepted standard [C-6A(40)] (for bolts where the tensile stress area is not defined, An shall be taken as the area at the root of the threads);

A_{sb} = shank area of the bolt;

f_{ub} = ultimate tensile stress of the bolt; and

γ_{mf} = partial factor of safety.

17.4.6 *Combined Shear and Tension*

Bolts in a connection for which slip in the serviceability limit state shall be limited, which are subjected to a tension force, *T*, and shear force, *V*, shall satisfy:

$$\left(\frac{V_{sf}}{V_{df}}\right)^2 + \left(\frac{T_f}{T_{df}}\right)^2 \le 1.0$$

where

V_{df} = design shear strength;

V_{sf} = applied factored shear at design load;

T_{df} = design tension strength; and

17.4.7 Where prying force, *Q* as illustrated in Fig. 16 shall be calculated as given below and added to the tension in the bolt:

$$Q = \frac{l_v}{2\,l_e}\left[T_e - \frac{\beta \eta\, f_o b_e t^4}{27 l_e l_v^2}\right]$$

where

l_e = distance between prying force and bolt centreline and is the minimum of either the end distance or the value given by; and

l_v = distance from the bolt centreline to the toe of the fillet weld or to half the root radius for a rolled section.

$$l_e = 1.1\,t\sqrt{\frac{\beta f_o}{f_y}}$$

where

β = 2 for non pre-tensioned bolt and 1 for pre-tensioned bolt;

b_e = effective width of flange per pair of bolts;

f_o = proof stress in consistent units;

η = 1.5; and

t = thickness of the end plate.

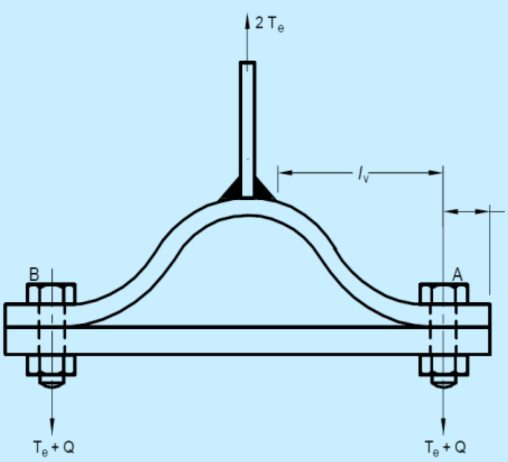

FIG. 16 COMBINED PRYING FORCE AND TENSION

17.5 Welds and Welding

17.5.1 *General*

Requirements of welds and welding shall conform to the accepted standards [C-6A(41)], as appropriate.

17.5.1.1 *End returns*

Fillet welds terminating at the ends or sides of parts should be returned continuously around the corners for a distance of not less than twice the size of the weld, unless it is impractical to do so. This is particularly important on the tension end of parts carrying bending loads.

17.5.1.2 *Lap joint*

In the case of lap joints, the minimum lap should not be less than four times the thickness of the thinner part joined or 40 mm, whichever is more. Single end fillet should be used only when lapped parts are restrained from openings. When end of an element is connected only by parallel longitudinal fillet welds, the length of the weld along either edge should not be less than the transverse spacing between longitudinal welds.

17.5.1.3 A single fillet weld should not be subjected to moment about the longitudinal axis of the weld.

17.5.2 *Size of Weld*

17.5.2.1 The size of normal fillets shall be taken as the minimum weld leg size. For deep penetration welds, where the depth of penetration beyond the root run is a minimum of 2.4 mm, the size of the fillet should be taken as the minimum leg size plus 2.4 mm.

17.5.2.2 For fillet welds made by semi-automatic or automatic processes, where the depth of penetration is considerably in excess of 2.4 mm, the size shall be taken considering actual depth of penetration subject to agreement between the purchaser and the contractor.

17.5.2.3 The size of fillet welds shall not be less than 3 mm. The minimum size of the first run or of a single run fillet weld shall be as given in Table 22, to avoid the risk of cracking in the absence of preheating.

17.5.2.4 The size of butt weld shall be specified by the effective throat thickness.

17.5.3 *Effective Throat Thickness*

17.5.3.1 The effective size of a fillet weld shall not be less than 3 mm and shall generally not exceed $0.7t$, or $1.0t$ under special circumstances, where t is the thickness of the thinner plate of elements being welded.

17.5.3.2 For the purpose of stress calculation in fillet welds joining faces inclined to each other, the effective throat thickness shall be taken as K times the fillet size, where K is a constant, depending upon the angle between fusion faces, as given in Table 23.

Table 22 Minimum Size of First Run or of a Single Run Fillet Weld

(*Clause* 17.5.2.3)

Sl No.	Thickness of Thicker Part mm		Minimum Size of First run mm
	Over	Up to and Including	
(1)	(2)	(3)	(4)
i)	—	10	3
ii)	10	20	5
iii)	20	32	6

Table 22 (*Concluded*)

Sl No.	**Thickness of Thicker Part** mm		**Minimum Size of First run** mm
	Over	Up to and Including	
(1)	(2)	(3)	(4)
iv)	32	50	8 of first run 10 for minimum size of weld

NOTES

1 When the minimum size of the fillet weld given in the table is greater than the thickness of the thinner part, the minimum size of the weld should be equal to the thickness of the thinner part. The thicker part shall be adequately preheated to prevent cracking of the weld.

2 Where the thicker part is more than 50 mm thick, special precautions like preheating should be taken.

Table 23 Values of *K* for Different Angles Between Fusion Faces

(*Clause* 17.5.3.2)

Sl No. (1)	**Angle Between Fusion Faces** (2)	**Constant, *K*** (3)
i)	60° to 90°	0.70
ii)	91° to 100°	0.65
iii)	101° to 106°	0.60
iv)	107° to 113°	0.55
v)	114° to 120°	0.50

17.5.3.3 The effective throat thickness of a complete penetration butt weld shall be taken as the thickness of the thinner part joined, and that of an incomplete penetration butt weld shall be taken as the minimum thickness of the weld metal common to the parts joined, excluding reinforcements.

17.5.4 *Effective Length or Area of Weld*

17.5.4.1 The effective length of fillet weld shall be taken as only that length which is of the specified size and required throat thickness. In practice the actual length of weld is made of the effective length shown in drawing plus two times the weld size, but not less than four times the size of the weld.

17.5.4.2 The effective length of butt weld shall be taken as the length of the continuous full size weld, but not less than four times the size of the weld.

17.5.4.3 The effective area of a plug weld shall be considered as the nominal area of the hole in the plane of the faying surface. These welds shall not be designed to carry stresses.

17.5.4.4 If the maximum length l_j of the side welds transferring shear along its length exceeds 150 times the throat size of the weld, t_t, the reduction in weld strength as per the long joint (*see* **17.5.7.3**) should be considered. For flange to web connection, where the welds are loaded for the full length, the above limitation would not apply.

17.5.5 *Intermittent Welds*

17.5.5.1 Unless otherwise specified, the intermittent fillet welding shall have an effective length of not less than four times the weld size, with a minimum of 40 mm.

17.5.5.2 The clear spacing between the effective lengths of intermittent fillet weld shall not exceed 12 and 16 times the thickness of thinner plate joined, for compression and tension joint, respectively, and in no case be more than 200 mm.

17.5.5.3 Unless otherwise specified, the intermittent butt weld shall have an effective length of not less than four times the weld size and the longitudinal space between the effective length of welds shall not be more than 16 times the thickness of the thinner part joined. The intermittent welds shall not be used in positions subject to dynamic, repetitive and alternating stresses.

17.5.6 *Weld Types and Quality*

For the purpose of this NBCS, weld shall be fillet, butt, slot or plug or compound welds. Welding electrodes shall conform to IS 814.

17.5.7 *Design Stresses in Welds*

17.5.7.1 *Shop welds*

17.5.7.1.1 *Fillet welds*

Design strength of a fillet weld, f_{wd} shall be based on its throat area and shall be given by:

$$f_{\mathrm{wd}} = f_{\mathrm{wn}} / \gamma_{\mathrm{mw}}$$

where

f_{u} = smaller of the ultimate stress of the weld or of the parent metal;

f_{wn} = $f_{\mathrm{u}} / \sqrt{3}$; and

γ_{mw} = partial safety factor (*see* Table 5).

17.5.7.1.2 *Butt welds*

Butt welds shall be treated as parent metal with a thickness equal to the throat thickness, and the stresses shall not exceed those permitted in the parent metal.

17.5.7.1.3 *Slot or plug welds*

The design shear stress on slot or plug welds shall be as per **17.5.7.1.1**.

17.5.7.2 *Site welds*

The design strength in shear and tension for site welds made during erection of structural members shall be calculated according to **17.5.7.1** but using a partial safety factor γ_{mw} of 1.5.

17.5.7.3 *Long joints*

When the length of the welded joint, l_{j} of a splice or end connection in a compression or tension element is greater than 150 t_{t}, the design capacity of weld (*see* **17.5.7.1.1**), f_{wd} shall be reduced by the factor:

$$\beta_{\mathrm{lw}} = 1.2 - \frac{0.2 l_{\mathrm{j}}}{150 t_{\mathrm{t}}} \leq 1.0$$

where

l_{j} = length of the joint in the direction of the force transfer; and

t_{t} = throat size of the weld.

17.5.8 *Fillet Weld Applied to the Edge of a Plate or Section*

17.5.8.1 Where a fillet weld is applied to the square edge of a part, the specified size of the weld should generally be at least 1.5 mm less than the edge thickness in order to avoid washing down of the exposed corner [*see* Fig. 17(A)].

17.5.8.2 Where the fillet weld is applied to the rounded toe of a rolled section, the specified size of the weld should generally not exceed 3/4 of the thickness of the section at the toe [*see* Fig. 17(B)].

17.5.8.3 Where the size specified for a fillet weld is such that the parent metal will not project beyond the weld, no melting of the outer cover or covers shall be allowed to occur to such an extent as to reduce the throat thickness (*see* Fig. 18).

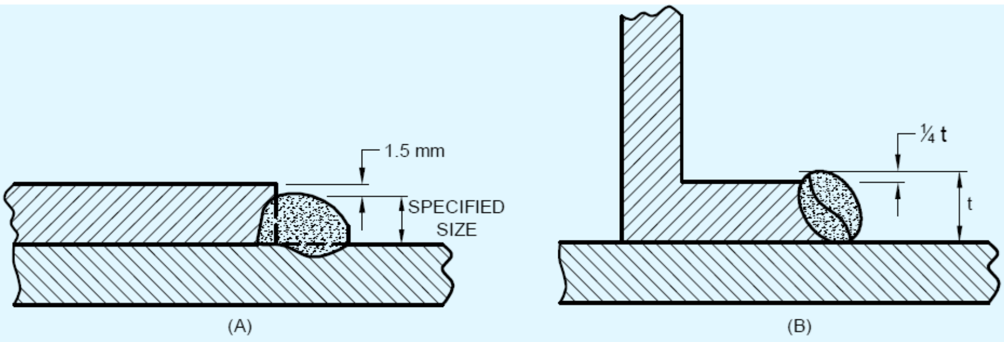

FIG. 17 FILLET WELDS ON SQUARE EDGE OF PLATE OR ROUND TOE OF ROLLED SECTION

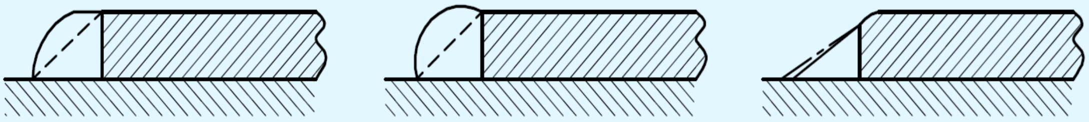

18 A DESIRABLE

18 B ACCEPTABLE BECAUSE OF FULL THROAT THICKNESS

18 C NOT ACCEPTABLE BECAUSE OF REDUCED THROAT THICKNESS

FIG. 18 FULL SIZE FILLET WELD APPLIED TO THE EDGE OF A PLATE OR SECTION

17.5.8.4 When fillet welds are applied to the edges of a plate or section in members subject to dynamic loading, the fillet weld shall be of full size with its leg length equal to the thickness of the plate or section, with the limitations specified in **17.5.8.3**.

17.5.8.5 End fillet weld, normal to the direction of force shall be of unequal size with a throat thickness not less than $0.5t$, where t is the thickness of the part, as shown in Fig. 19. The difference in thickness of the welds shall be negotiated at a uniform slope.

17.5.9 *Stresses Due to Individual Forces*

When subjected to either compressive or tensile or shear force alone, the stress in the weld is given by and shall be less than or equal to design strength of the weld, f_{ws}, given in **17.5.7.1.1**:

$$f_a \text{ or } q = \frac{P}{t_t\, l_w}$$

where

f_a = Calculated, in N/mm^2, normal stress due to axial force;

l_w = Effective, in mm, length of weld;

P = force transmitted (axial force N or the shear force Q);

q = shear, in N/mm^2, stress; and

t_t = Effective, in mm; throat thickness of weld.

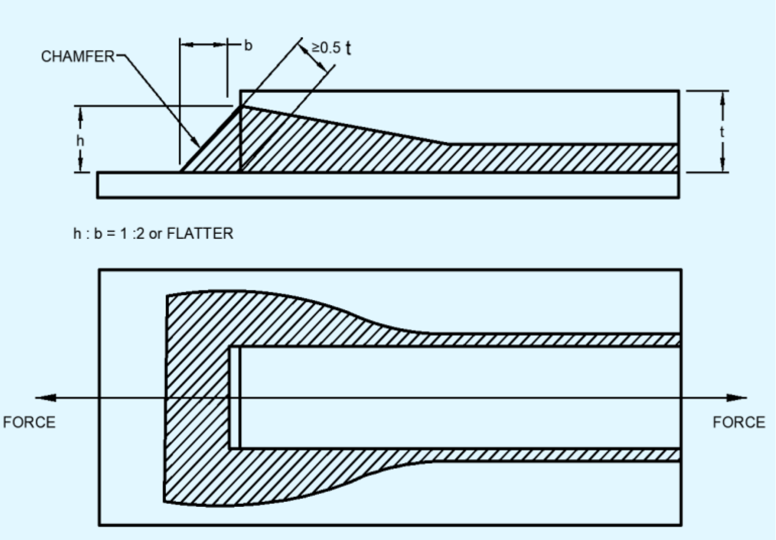

FIG. 19 END FILLET WELD NORMAL TO DIRECTION OF FORCE

17.5.10 *Combination of Stresses*

17.5.10.1 *Fillet welds*

17.5.10.1.1 When subjected to a combination of normal and shear stress, the equivalent stress f_e shall satisfy the following:

$$f_e = \sqrt{f_a^2 + 3q^2} \le \frac{f_u}{\gamma_{mw}}$$

where

f_a = normal stresses, compression or tension, due to axial force or bending moment (*see* **17.5.9**); and

q = shear stress due to shear force or tension (*see* **17.5.9**).

17.5.10.1.2 Check for the combination of stresses need not be done for:

a) side fillet welds joining cover plates and flange plates; and

b) fillet welds where algebraic sum of normal and shear stresses does not exceed f_{wd} (*see* **17.5.7.1.1**).

17.5.10.2 *Butt welds*

17.5.10.2.1 Check for the combination of stresses in butt welds need not be carried out provided that:

a) butt welds are axially loaded; and

b) in single and double bevel welds the algebraic sum of normal and shear stresses does not exceed the design normal stress, and the shear stress does not exceed 50 percent of the design shear stress.

17.5.10.2.2 *Combined bearing, bending and shear*

Where bearing stress, f_{br} is combined with bending (tensile or compressive), f_b and shear stresses, q under the most unfavorable conditions of loading in butt welds, the equivalent stress, f_e as obtained from the following formula, shall not exceed the values allowed for the parent metal:

$$f_e = \sqrt{{f_b}^2 + {f_{br}}^2 - f_b\, f_{br} + 3q^2}$$

where

f_b = calculated, in N/mm^2; stress due to bending;

f_{br} = calculated, in N/mm^2, stress due to bearing;

f_e = equivalent stress; and

q = shear, in N/mm^2, stress.

17.5.11 Where a packing is welded between two members and is less than 6 mm thick, or is too thin to allow provision of adequate welds or to prevent buckling, the packing shall be trimmed flush with the edges of the element subject to the design action and the size of the welds along the edges shall be increased over the required size by an amount equal to the thickness of the packing. Otherwise, the packing shall extend beyond the edges and shall be fillet welded to the pieces between which it is fitted.

17.6 Design of Connections

Each element in a connection shall be designed so that the structure is capable of resisting the design actions. Connections and adjacent regions of the members shall be designed by distributing the design action effects such that the following requirements are satisfied:

a) Design action effects distributed to various elements shall be in equilibrium with the design action effects on the connection;

b) Required deformations in the elements of the connections are within their deformations capacities;

c) All elements in the connections and the adjacent areas of members shall be capable of resisting the design action effects acting on them; and

d) Connection elements shall remain stable under the design action effects and deformations.

17.6.1 Connections can be classified as rigid, semi-rigid and flexible for the purpose of analysis and design as per the recommendation in Annex F. Connections with sufficient rotational stiffness may be considered as rigid. Examples of rigid connections include flush end-plate connection and extended end-plate connections. Connections with negligible rotational stiffness may be considered as flexible (pinned). Examples of flexible connections include single and double web angle connections and header plate connections. Where a connection cannot be classified as either rigid or flexible, it shall be assumed to be semi-rigid. For Example, of semi-rigid connections include top and seat angle connection and top and seat angle with single/double web angles.

17.6.2 Design shall be on the basis of any rational method supported by experimental evidence. Residual stresses due to installation of bolts or welding normally need not be considered in statically loaded structures. Connections in cyclically loaded structures shall be designed considering fatigue as given under **19**. For earthquake load combinations, the connections shall be designed to withstand the calculated design action effects as specified in **18**.

17.6.3 Beam and column splice shall be designed in accordance with the recommendation given in **F-2** and **F-3**.

17.7 Minimum Design Action on Connection

Connections carrying design action effects, except for lacing connections, connections of sag rods, purlins and girts, shall be designed to transmit the greater of:

a) the design action in the member; and

b) The minimum design action effects expressed either as the value or the factor times the member design capacity for the minimum size of member required by the strength limit state, specified as follows:

1) *Connections in rigid construction* — A bending moment of at least 0.5 times the member design moment capacity;

2) *Connections to beam in simple construction* — A shear force of at least 0.15 times the member design shear capacity or 40 kN, whichever is lesser;

3) *Connections at the ends of tensile or compression member* — A force of at least 0.3 times the member design capacity;

4) *Splices in members subjected to axial tension* — A force of at least 0.3 times the member design capacity in tension;

5) *Splices in members subjected to axial compression* — For ends prepared for full contact in accordance with **24.7.1**, it shall be permissible to carry compressive actions by bearing on contact surfaces. When members are prepared for full contact to bear at splices, there shall be sufficient fasteners to hold all parts securely in place. The fasteners shall be sufficient to transmit a force of at least 0.15 times the member design capacity in axial compression;

   When members are not prepared for full contact, the splice material and its fasteners shall be arranged to hold all parts in line and shall be designed to transmit a force of at least 0.3 times the member design capacity in axial compression.

   In addition, splices located between points of effective lateral support shall be designed for the design axial force, P_d plus a design bending moment, not less than the design bending moment $M_d = P_d l_s / 1\,000$ where, l_s is the distance between points of effective lateral support.

6) *Splices in flexural members* — A bending moment of 0.3 times the member design capacity in bending. This provision shall not apply to splices designed to transmit shear force only; and

   A splice subjected to a shear force only shall be designed to transmit the design shear force together with any bending moment resulting from the eccentricity of the force with respect to the centroid of the group.

7) *Splices in members subject to combined actions* — A splice in a member subject to a combination of design axial tension or design axial compression and design bending moment shall satisfy requirements in (4), (5) and (6) above, simultaneously.

17.8 Intersections

Members or components meeting at a joint shall be arranged to transfer the design actions between the parts, wherever practicable, with their centroidal axes meeting at a point. Where there is eccentricity at joints, the members and components shall be designed for the design bending moments which result due to eccentricity.

The disposition of fillet welds to balance the design actions about the centroidal axis or axes for end connections of single angle, double angle and similar type members is not required for statically loaded members but is required for members, connection components subject to fatigue loading.

Eccentricity between the centroidal axes of angle members and the gauge lines for their bolted end connections may be neglected in statically loaded members, but shall be considered in members and connection components subject to fatigue loading.

17.9 Choice of Fasteners

Where slip in the serviceability limit state is to be avoided in a connection, high-strength bolts in a friction-type joint, fitted bolts or welds shall be used.

Where a joint is subjected to impact or vibration, either high strength bolts in a friction type joint or ordinary bolts with locking devices or welds shall be used.

17.10 Connection Components

Connection components (cleats, gusset plates, brackets and the like) other than connectors, shall have their capacities assessed using the provisions of 12, 13, 14, 15 and 16, as applicable.

17.11 Analysis of a Bolt/Weld Group

17.11.1 *Bolt/Weld Group Subject to In-plane Loading*

17.11.1.1 *General method of analysis*

The design force in a bolt/weld or design force per unit length in a bolt/weld group subject to in-plane loading shall be determined in accordance with the following:

a) The connection plates shall be considered to be rigid and to rotate relative to each other about a point known as the instantaneous centre of rotation of the group;

b) In the case of a group subject to a pure couple only, the instantaneous centre of rotation coincides with the group centroid. In the case of in-plane shear force applied at the group centroid, the instantaneous centre of the rotation is at infinity and the design force is uniformly distributed throughout the group. In all other cases, either the results of independent analyses for a pure couple alone and for an in-plane shear force applied at the group centroid shall be superposed, or a recognized method of analysis shall be used; and

c) The design force in a bolt or design force per unit length at any point in the group shall be assumed to act at right angles to the radius from that point to the instantaneous centre, and shall be taken as proportional to that radius.

17.11.2 *Bolt/Weld Group Subject to Out-of-Plane Loading*

17.11.2.1 *General method of analysis*

The design force of a bolt in bolt group or design force per unit length in the fillet weld group subject to out-of-plane loading shall be determined in accordance with the following:

a) Design force in the bolts or per unit length in the fillet weld group resulting from any shear force or axial force shall be considered to be equally shared by all bolts in the group or uniformly distributed over the length of the fillet weld group; and

b) Design force resulting from a design bending moment shall be considered to vary linearly with distance from the relevant centroidal axes. The following shall also be considered:

   1) in bearing type of bolt group plates in the compression side of the neutral axis and only bolts in the tension side of the neutral axis may be considered for calculating the neutral axis and second moment of area;

   2) in the friction grip bolt group, only the bolts shall be considered in the calculation of neutral axis and second moment of area; and

   3) the fillet weld group shall be considered in isolation from the connected element; for the calculation of centroid and second moment of the weld length.

17.11.2.2 *Alternative analysis*

The design force per unit length in a fillet weld/bolt group may alternatively be determined by considering the fillet weld group as an extension of the connected member and distributing the design forces among the welds of the fillet weld group so as to satisfy equilibrium between the fillet weld group and the elements of the connected member.

17.11.3 *Bolt/Weld Group Subject to In-plane and Out-of-Plane Loading*

17.11.3.1 *General method of analysis*

The design force in a bolt or per unit length of the weld shall be determined by the superposition of analysis for in-plane and out-of-plane cases discussed in 17.11.1 and 17.11.2.

17.11.3.2 *Alternative analysis*

The design force in a bolt or per unit length in the fillet weld group may alternatively be determined by considering the fillet weld group as an extension of the connected member and proportioning the design force per bolt or unit length in the weld group to satisfy equilibrium between the bolt/weld group and the elements of the connected member.

Force calculated in the most stressed bolt or highest force per unit length of the weld shall satisfy the strength requirements of **17.3**, **17.4** or **17.5**, as appropriate.

17.12 Lug Angles

17.12.1 Lug angles connecting outstanding leg of a channel-shaped member shall, as far as possible, be disposed symmetrically with respect to the section of the member.

17.12.2 In the case of angle members, the lug angles and their connections to the gusset or other supporting member shall be capable of developing a strength not less than 20 percent in excess of the force in the outstanding leg of the member, and the attachment of the lug angle to the main angle shall be capable of developing a strength not less than 40 percent in excess of the force in the outstanding leg of the angle.

17.12.3 In the case of channel members and the like, the lug angles and their connection to the gusset or other supporting member shall be capable of developing a strength of not less than 10 percent in excess of the force not accounted for by the direct connection of the member, and the attachment of the lug angles to the member shall be capable of developing 20 percent in excess of that force.

17.12.4 In no case shall fewer than two bolts, rivets or equivalent welds be used for attaching the lug angle to the gusset or other supporting member.

17.12.5 The effective connection of the lug angle shall, as far as possible terminate at the end of the member connected, and the fastening of the lug angle to the main member shall preferably start in advance of the direct connection of the member to the gusset or other supporting member.

17.12.6 Where lug angles are used to connect an angle member, the whole area of the member shall be taken as effective notwithstanding the requirements given under **13**.

18 DESIGN AND DETAILING FOR EARTHQUAKE EFFECTS

18.1 General

18.1.1 Earthquake is a ‘displacement loading’ on a structure. This implies that ‘displacements’ are ‘imposed’ under a structure during earthquake shaking and ‘forces’ are induced in it. Thus, a structure is allowed to be designed to have lesser strength capacity than that required if it were to remain elastic. And, only chosen types of damage are permitted to be accrued in select components of a structure during strong earthquake shaking.

Thus, reliance is placed on the nonlinear response of a structure, especially on its deformation and ductility capacities. These must be achieved by adopting special design and detailing practices. Therefore, steel frames shall be so designed and detailed as to give them stability, and adequate stiffness, strength, and ductility capacities to resist severe earthquake shaking without collapse in all earthquake zones mentioned in **5** of Part C ‘Structural Design/Section 1 Loads and Load Effects’ of this NBCS.

18.1.2 Steel frames required to resist earthquake effects in all earthquake zones shall satisfy the requirements specified in good practice [C-6A(42)]. Frames are classified into two types, one which have minimal inelastic deformation and ductility capacities, called ordinary frames, and one with higher deformation and ductility capacities, called special frames. For earthquake zones III and above, only special frames are permitted to be used.

18.1.3 For earthquake zone II, ordinary frames, namely ordinary moment frames (OMF) and ordinary concentrically braced frames (OCBF), are permitted to be used. In design and detailing of OMFs and OCBFs, specific requirements of this Section shall be satisfied along with other provisions of this NBCS, in addition to the earthquake demand and design criteria requirements of **5** of Part C ‘Structural design/Section 1 Loads and Load Effects’ of this NBCS.

18.1.4 Frames, which are a part of the gravity load resisting system and are not intended to resist the lateral earthquake forces, need not satisfy the requirements of this section, provided they can accommodate the resulting earthquake shaking induced deformation without premature failure.

18.2 Loads and Load Combinations

18.2.1 Earthquake loads shall be calculated as per **5** of Part C 'Structural design/Section 1 Loads and Load Effects' of this NBCS, except that the reduction factors recommended in **18.3** may be used.

18.2.2 In the limit state design of frames resisting earthquake loads, the load combinations shall conform to Table 4.

18.2.3 In addition the following load combination shall be considered as required in **18.5.1.1**, **18.7.3.1**, **18.11.2.2** and **18.11.3.4**:

a) 1.2 Dead Load (DL) + 0.5 Imposed Load (IL) ± 2.5 Earthquake Force (E); and

b) 0.9 Dead Load (DL) ± 2.5 Earthquake Force (E).

18.3 Response Reduction Factor

18.3.1 For structures designed and detailed in accordance with the provisions of this Section, the response reduction factors specified herein may be used for calculating the design earthquake forces, in conjunction with the provisions of **5** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS.

18.3.2 For braced frame systems, the response reduction factor (R) for ordinary concentrically braced frames (OCBF), for special concentrically braced frames (SCBF) and for special eccentrically braced frames (SEBF) shall be taken from **5** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS. The response reduction factor (R) for ordinary eccentrically braced frames (OEBF) shall be taken as 4.5.

18.3.3 For moment frame systems, the response reduction factor (R) for special moment frames (SMF) shall be taken from **5** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS. For the Ordinary Moment Frames (OMF) designed as per **18.10**, the response reduction factor (R) shall be taken as 4.0.

18.3.4 For non-ductile frames (NDF), the response reduction factor (R) shall be taken as 1.5.

18.3.5 The braced and moment resisting frames in single storey industrial buildings can be designed as non-ductile frames (NDF), if their overall height to overall width ratio does not exceed 1.0. Such frames need not meet the ductility requirements of other types of frames as specified in **18.4** to **18.12**.

18.4 Connections, Joints and Fasteners

18.4.1 All bolts used in critical zones of frames designed to resist earthquake effects shall be fully tensioned high strength friction grip (HSFG) bolts or turned and fitted bolts. The critical zones of frames are zones of plastic hinges of moment resisting frames and beam to columns as well as bracing and their connections of braced frames. The plastic hinge zones shall be taken as a distance equal to 2 times the depth of the member from the section of maximum bending moment.

18.4.2 All welds used in frames designed to resist earthquake effects shall be complete penetration butt welds, except in column splices, which shall conform to **18.5.2**.

18.4.3 Bolted joints shall be designed not to share load in combination with welds on the same faying surface.

18.5 Columns

18.5.1 *Column Strength*

When P_u/P_d *is* greater than 0.4, the requirements in **18.5.1.1** and **18.5.1.2** shall be met.

Where

P_u = required ultimate compressive strength of the member; and

P_d = design resistance in axial compression as obtained from **14.1.2**.

18.5.1.1 The required axial compressive and axial tensile strength in the absence of applied moment, shall be determined from the load combination in **18.2.3**.

18.5.1.2 The required strength determined in **18.5.1.1** need not exceed either of the maximum load transferred to the column considering 1.2 times the nominal strength of the connecting beam or brace element, or the resistance of the foundation to uplift.

18.5.2 *Column Splice*

18.5.2.1 A partial-joint penetration groove weld may be provided in column splice, such that the design strength of the joints shall be at least equal to 200 percent of the required strength.

18.5.2.2 The minimum required strength for each flange splice shall be 1.2 times $A_f f_y$ as shown Fig. 20, where A_f is the area of each flange in the smaller connected column.

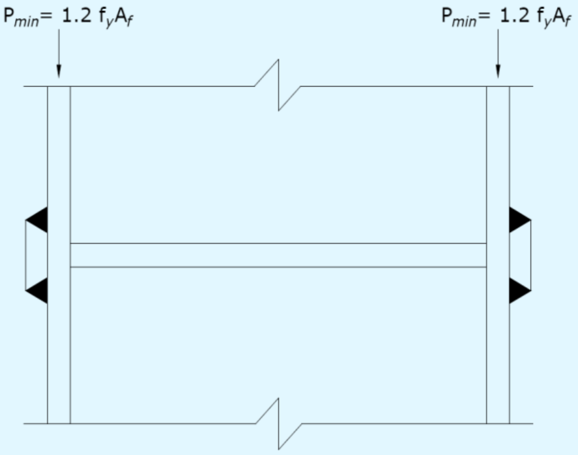

FIG. 20 PARTIAL PENETRATION GROOVE WELD IN COLUMN SPLICES

18.6 Storey Drift

The storey drift limits shall conform to **5** of Part C 'Structural design/Section 1 Loads and Load Effects' of this NBCS. The deformation compatibility of members not designed to resist seismic lateral load shall also conform to **5** of Part C 'Structural design/Section 1 Loads and Load Effects' of this NBCS.

18.7 Ordinary Concentrically Braced Frames (OCBF)

18.7.1 Ordinary concentrically braced frames (OCBF) should be shown to withstand inelastic deformation a moment of 1.2 times the full plastic moment of the corresponding to a joint rotation of at least 0.02 radians without degradation in strength and stiffness below the full yield value. Ordinary concentrically braced frames meeting the requirements of this section shall be deemed to satisfy the required inelastic deformation.

18.7.1.1 Ordinary concentrically braced frames shall not be used in seismic zones IV and above and for buildings with importance factor greater than unity (1 > 1.0) in
seismic zone III.

18.7.1.2 The provision in this section apply for diagonal and X-bracing only. Specialist literature may be consulted for V and inverted V-type bracing. K-bracing shall not be permitted in systems to resist earthquake.

18.7.2 *Bracing Members*

18.7.2.1 The slenderness of bracing members shall not exceed 120.

18.7.2.2 The required compressive strength of bracing member shall not exceed 0.8 times P_d, where P_d is the design strength in axial compression (*see* **14.1.2**).

18.7.2.3 Along any line of bracing, braces shall be provided such that for lateral loading in either direction, the tension braces will have to resist between 30 to 70 percent of the total lateral load.

18.7.2.4 Bracing cross-section can be plastic, compact or semi-compact, but not slender, as defined in **10.8.2**.

18.7.2.5 For all built-up braces, the spacing of tack fasteners shall be such that the unfavorable slenderness ratio of individual element, between such fasteners, shall not exceed 0.4 times the governing slenderness ratio of the brace itself. Bolted connections shall be avoided within the middle one-fourth of the clear brace length (0.25 times the length in the middle).

18.7.2.6 The bracing members shall be designed so that gross area yielding (*see* **13.2**) and not the net area rupture (*see* **13.3**) would govern the design tensile strength.

18.7.3 *Bracing Connections*

18.7.3.1 End connections in bracings shall be designed to withstand the minimum of the following:

a) A tensile force in the bracing equal to 1.2 $f_y A_g$;

b) Force in the brace due to load combinations in **18.2.3**; and

c) Maximum force that can be transferred to the brace by the system.

18.7.3.2 The connection should be checked for tension rupture and block shear under the load determined in **18.7.3.1**.

18.7.3.3 The connection shall be designed to withstand should be shown to withstand inelastic deformation a moment of 1.2 times the full plastic moment of the corresponding to a joint rotation of at least 0.02 radians braced section about the buckling axis.

18.7.3.4 Gusset plates shall be checked for buckling out of their plane.

18.8 Special Concentrically Braced Frames (SCBF)

18.8.1 Special concentrically braced frames (SCBF) should be shown to withstand inelastic deformation corresponding to a joint rotation of at least 0.04 radians without degradation in strength and stiffness below the full yield value. Special concentrically braced frames meeting the requirements of this section shall be deemed to satisfy the required inelastic deformation.

18.8.1.1 Special concentrically braced frames (SCBF) may be used in any seismic zone as defined in **5** of Part C 'Structural design/Section 1 Loads and Load Effects' of this NBCS and for any building.

18.8.1.2 The provision in this section apply for diagonal and X-bracing only. Specialist literature may be consulted for V and inverted V-type bracing. K-bracing shall not be permitted in system to resist earthquake.

18.8.2 *Bracing Members*

18.8.2.1 Bracing members shall be made of E 250B steel of accepted standard [C-6A(6)] only.

18.8.2.2 The slenderness of bracing members shall not exceed 160 (only hangers).

18.8.2.3 The required compressive strength of bracing member shall not exceed the design strength in axial compression P_d (*see* **14.1.2**).

18.8.2.4 Along any line of bracing, braces shall be provided such that for lateral loading in either direction, the tension braces will resist between 30 percent to 70 percent of the load.

18.8.2.5 Braced cross-section shall be plastic as defined in **10.8.2**.

18.8.2.6 In built-up braces, the spacing of tack connections shall be such that the slenderness ratio individual element between such connections shall not exceed 0.4 times the governing slenderness ratio of the brace itself. Bolted connection shall be avoided.

18.8.3.4 Gusset plates shall be checked for buckling out of their plane.

18.8.4 ***Column***

18.8.4.1 The column sections used in special concentrically braced frames (SCBF) shall be plastic as defined in **10.8.2**.

18.8.4.2 Splices shall be located within the middle one-third of the column clear height. Splices shall be designed for the forces that can be transferred to it. In addition, splices in columns shall be designed to develop at least the nominal shear strength of the smaller connected section.

18.9 Eccentrically Braced Frames (EBF)

18.9.1 Ordinary eccentrically braced frames (OEBF) and Special eccentrically braced frames (SEBF) shall be designed in accordance with specialist literature.

18.10 Ordinary Moment Frames (OMFs)

Ordinary moment frames (OMFs) of structural steel shall be designed to satisfy the requirements of this section.

18.10.1 *Basis of Design*

Ordinary moment frames designed in accordance with these provisions are expected to possess limited inelastic deformation capacity through flexural yielding of the beams, panel zones, and columns.

18.10.2 *Analysis*

When two moment frames oriented in orthogonal directions intersect, the possibility of beam yielding in both orthogonal directions simultaneously shall be considered in the estimation of design demand on the common column.

18.10.3 *Member Requirements*

The requirements specified hereunder shall be satisfied by the component or member.

18.10.3.1 *Beams*

Beam cross-section shall be plastic or compact, as defined in **10.8.2**.

18.10.3.2 *Columns*

Column cross-section shall be plastic or compact, as defined in **10.8.2**.

18.10.4 *System Requirements*

It is preferable to plan buildings to have independent lateral load resisting moment frames in the vertical plane along each principal plan direction. Also, the requirements given hereunder shall be satisfied by the building system.

18.10.4.1 *Beam-to-column connections*

Beam-to-column connections may be rigid or semi-rigid moment connections, but shall satisfy the following criteria:

a) Rigid moment connections shall be designed to withstand a moment of at least 1.2 times of either the full plastic moment of the connected beam or the maximum moment that can be delivered by the beam to the joint due to the induced weakness at the ends of the beam, whichever is less.

b) Semi-rigid connections shall be designed and to withstand either a moment of at least 0.5 times the full plastic moment of the connected beam or the maximum moment that can be delivered by the system, whichever is less. The design moment shall be achieved within a rotation of 0.01 radians. The information given in Annex F may be used for checking.

c) The stiffness and strength of semi-rigid connections shall be accounted for in the design and the overall stability of the frame shall be ensured.

d) The rigid and semi-rigid connections shall be designed to withstand a shear resulting from the load combination 1.2 DL + 0.5 LL plus the shear corresponding to the design moment defined in **(a)** and **(b)**, respectively.

e) In rigid fully welded connections, continuity plates of thickness equal to or greater than the thickness of the beam flange shall be provided and welded to the column flanges and web.

18.10.4.2 *Column to beam strength ratio*

At a beam–column joint, strong column - weak beam design shall be adopted, suitably accounting for the reduction in moment capacity of columns due to axial load.

18.11 Special Moment Frames (SMF)

18.11.1 Special moment frames (SMF) shall be made of E250B steel of accepted standard [C-6A(6)] and should be shown to withstand inelastic deformation corresponding to a joint rotation of 0.04 radians without degradation in strength and stiffness below the full yield value (M_P). Special moment frames meeting the requirements of this section shall be deemed to satisfy the required inelastic deformation.

18,11.1.1 Special moment frames (SMF) maybe used in any seismic zone and for any buildings.

18.11.2 *Beam-to-Column Joints and Connections*

18.11.2.1 All beam-to-column connections shall be rigid (*see* Annex F) and designed to withstand a moment of at least 1.2 times the full plastic moment of the connected beam. When a reduced beam section is used, its minimum flexural strength shall be at least equal to 0.8 times the full plastic moment of the unreduced section.

18.11.2.2 The connection shall be designed to withstand a shear resulting from the load combination 1.2 DL + 0.5LL plus the shear resulting from the application of $1.2M_P$ in the same direction, at each end of the beam (causing double curvature bending). The shear strength need not exceed the required value corresponding to the load combination in **18.2.3**.

18.11.2.3 In column strong axis connections (beam and column web in the same plane), the panel zone shall be checked for shear buckling in accordance with **15.4.2** at the design shear defined in **18.11.2.2**. Column web doubler plates or diagonal stiffeners may be used to strengthen the web against shear buckling.

18.11.2.4 The individual thickness of the column webs and doubler plates (*see* Fig. 21), shall satisfy the following:

$$t \geq (d_P + b_P)/90$$

where

t = Thickness of the column web or doubler plate

d_P = Panel zone depth between continuity plates

b_P = Panel zone width between column flanges

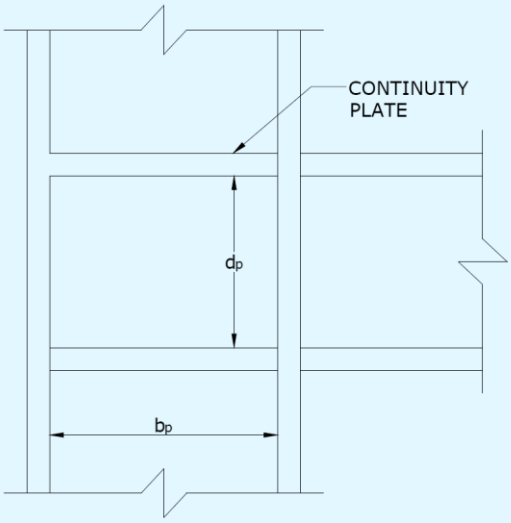

FIG. 21 CONTINUITY PLATES

18.11.2.5 Continuity plates (tension stiffener) (*see* **15.7**) shall be provided in all strong axis welded connections except in end plate connection.

18.11.3 *Beam and Column Limitation*

18.11.3.1 Beam and column sections shall be either plastic or compact as defined in **10.8.2**. At potential plastic hinge locations, they shall necessarily be plastic**.**

18.11.3.2 The section selected for beams and columns shall satisfy the following relation:

$$\frac{\sum M_{\mathrm{Pc}}}{\sum M_{\mathrm{Pb}}} \geq 1.2$$

where

M_{Pc}= sum of the moment capacity in the column above and below the beam centreline; and

M_{Pb} = sum of the moment capacity in the beams at the intersection of the beam and column centrelines.

In tall buildings, higher mode effects shall be accounted for in accordance with specialist literature.

18.11.3.3 Lateral support to the column at both top and bottom beam flange levels shall be provided so as to resist at least 2 percent of the beam flange strength, except for the case described in **18.11.3.4**.

18.11.3.4 A plane frame designed as non-sway in the direction perpendicular to its plane, shall be checked for buckling, under the load combination specified in **18.2.3**.

18.12 Column Bases

18.12.1 Fixed column bases and their anchor bolts should be designed to withstand a moment of 1.2 times the full plastic moment capacity of the column section. The anchor bolts shall be designed to withstand the combined action of shear and tension as well as prying action, if any.

18.12.2 Both fixed and hinged column bases shall be designed to withstand the full shear under any load case or 1.2 times the shear capacity of the column section, whichever is higher.

18.13 Industrial Structures

18.13.1 Single storey industrial buildings with frame height to span ratio less than 1.0 and with regular configuration need not meet the ductility requirements of other types of frames specified in **18.3**, **18.4** or in good practice[C-6A(42)], provided they satisfy the requirements in **18.13.2** and **18.13.3**.

18.13.2 Braced frames or moment frames are permitted as lateral force resisting system and shall be designed using R = 1.5 as prescribed for NDF.

18.13.3 Connections in lateral force resisting systems to resist earthquake shall be designed for full member capacity except those in earthquake zone V, where the connections shall be designed for 50 percent extra force.

19 FATIGUE

19.1 General

Structure and structural elements subject to loading that could lead to fatigue failure shall be designed against fatigue as given in this section. This shall however not cover the following:

a) Corrosion fatigue;
b) Low cycle (high stress) fatigue;
c) Thermal fatigue;
d) Stress corrosion cracking;
e) Effects of high temperature (> 150 °C); and
f) Effects of low temperature (< brittle transition temperature).

For the purpose of design against fatigue, different details (of members and connections) are classified under different fatigue class. The design stress range corresponding to various number of cycles, are given for each fatigue class. The requirements of this Section shall be satisfied with, at each critical location of the structure subjected to cyclic loading, considering relevant number of cycles and magnitudes of stress range expected to be experienced during the life of the structure.

19.2 Design

19.2.1 *Reference Design Condition*

The standard S-N curves for each detail category are given for the following conditions:

a) Detail is located in a redundant load path, wherein local failure at that detail alone will not lead to overall collapse of the structure;
b) Nominal stress history at the local point in the detail is estimated/evaluated by a conventional method without taking into account the local stress concentration effects due to the detail;
c) Load cycles are not highly irregular;
d) Details are accessible for and subject to regular inspection;
e) Structure is exposed to only mildly corrosive environment as in normal atmospheric condition and suitably protected against corrosion (pit depth < 1 mm);

f) Structure is not subjected to temperature exceeding 150 °C; and

g) Transverse fillet or butt weld connects plates of thickness not greater than 25 mm.

19.2.1.1 *Thickness correction factor*

The values obtained from the standard S-N curve shall be modified by a capacity reduction factor μ_r, when plates greater than 25 mm in thickness are joined together by transverse fillet or butt welding, given by:

$$\mu_r = (25/t_p)^{0.25} \leq 1.0$$

where

t_p = actual thickness of the thicker plate being joined, in mm.

No thickness correction is necessary when full penetration butt weld reinforcements are machined flush and proved free of defect through nondestructive testing.

19.2.1.2 *Necessity for fatigue assessment*

a) Fatigue assessment is not normally required for building structures except as follows; and
   1) Members supporting lifting or rolling loads;
   2) Member subjected to repeated stress cycles from vibrating machinery;
   3) Members subjected to wind induced oscillations of a large number of cycles in life; and
   4) Members subjected to crowd induced oscillations of a large number of cycles in life.

b) No fatigue assessment is necessary if the following conditions are satisfied.
   1) The highest normal stress range $f_{\mathrm{f\,max}}$ satisfies:

$$f_{\mathrm{fmax}} \leq 27\mu_{\mathrm{r}} / \gamma_{\mathrm{mft}}$$

   2) The highest shear stress range τ_{fmax} satisfies:

$$\tau_{\mathrm{fmax}} \leq 67\mu_r / \gamma_{\mathrm{mft}}$$

   3) The total number of actual stress cycles N_{SC}, satisfies:

$$N_{\mathrm{SC}} \leq 5\times10^6 \left(\frac{27\mu_r}{\gamma_{\mathrm{mft}}\ f_{\mathrm{feq}}} \right)^3$$

where

f_{feq} = equivalent constant amplitude stress range, in MPa, given by.

$$f_{\mathrm{feq}} = \left[\frac{\sum_{i=1}^{r5} n_i f_{\mathrm{i}}^3 + \sum_{j=\mathrm{r}5}^{r} n_{\mathrm{j}} f_{\mathrm{j}}^5}{n} \right]^{1/3}$$

where

$f_{\mathrm{i}}, f_{\mathrm{j}}$ = stress ranges falling above and below the ffn, the stress range corresponding to the detail at 5 × 10^6 number of life cycles.

$$n = \sum_{i=1}^{r} n_{\mathrm{i}}$$

19.2.2 *Design Spectrum*

19.2.2.1 *Stress evaluation*

Design stress shall be determined by elastic analysis of the structure to obtain stress resultants and the local stresses may be obtained by a conventional stress analysis method. The normal and shear stresses shall be determined considering all design actions on the members, but excluding stress concentration due to the geometry of the detail. The stress concentration effect is accounted for in detail category classification (*see* Table 26). The stress concentration, however, not characteristic of the detail shall be accounted for separately in the stress calculation.

In the fatigue design of trusses made of members with open sections, in which the end connections are not pinned, the stresses due to secondary bending moments shall be taken into account, unless the slenderness ratio (KL/r), of the member is greater than 40.

In the determination of stress range at the end connections between hollow sections, the effect of connection stiffness and eccentricities may be disregarded, provided:

a) the calculated stress range is multiplied by appropriate factor given in Table 24(A) in the case of circular hollow section connections and Table 24(B) in the case of rectangular hollow section connections; and
b) the design throat thickness of fillet welds in the joints is greater than the wall thickness of the connected member.

19.2.2.2 *Design stress spectrum*

In the case of loading events producing non-uniform stress range cycle, the stress spectrum may be obtained by a rational method, such as ‘rain flow counting’ or an equivalent method.

19.2.3 *Partial Safety Factors*

19.2.3.1 *Partial safety factor for actions and their effects* (γ_{fft})

Unless and otherwise the uncertainty in the estimation of the applied actions and their effects demand a higher value, the partial safety factor for loads in the evaluation of stress range in fatigue design shall be taken as 1.0.

19.2.3.2 *Partial safety factor for fatigue strength* (γ_{mft})

Partial safety factor for strength is influenced by consequences of fatigue damage and level of inspection capabilities.

19.2.3.3 Based on consequences of fatigue failure, component details have been classified as given in the Table 25 and the corresponding partial safety factor for fatigue strength shall be used:

a) failsafe structural component/detail is the one where local failure of one component due to fatigue crack does not result in the failure of the structure due to availability of alternate load path (redundant system); and

b) non-failsafe structural component/detail is the one where local failure of one component leads rapidly to failure of the structure due to its non-redundant nature.

Sl No.	**Inspection and Access**	**Consequence of Failure**	
		Failsafe	Non-failsafe
(1)	(2)	(3)	(4)
i)	Periodic inspection, maintenance and accessibility to detail is good	1.00	1.25
ii)	Periodic inspection, maintenance and accessibility to detail is poor	1.15	1.35

19.3 Detail Category

Table 26(A) to Table 26 (D) indicate the classification of different details into various categories for the purpose of assessing fatigue strength. Details not classified in the table may be treated as the lowest detail category of a similar detail, unless superior fatigue strength is proved by testing and/or analysis.

Holes in members and connections subjected to fatigue loading shall not be made:

a) using punching in plates having thickness greater than 12 mm unless the holes are sub-punched and subsequently reamed to remove the affected material around the punched hole; and

b) using gas cutting unless the holes are reamed to remove the material in the heat affected zone.

19.4 Fatigue Strength

The fatigue strength of the standard detail for the normal or shear fatigue stress range, not corrected for thickness effects discussed in 19.2.1, is given below (*see* also Fig. 22 and Fig. 23):

a) Normal stress range:

1) when $N_{\mathrm{SC}} \leq 5 \times 10^6$

$$f_{\mathrm{f}} = f_{fn} \sqrt[3]{5 \times 10^6 / N_{\mathrm{sc}}}$$

2) when $5 \times 10^6 \leq N_{\mathrm{SC}} \leq 10^8$

$$f_f = f_{fn}\sqrt[5]{5\times10^6/N_{sc}}$$

b) Shear stress:

$$\tau_f = \tau_{fn}\sqrt[5]{5\times10^6/N_{sc}}$$

where

f_f, τ_f = design normal and shear fatigue stress range of the detail, respectively, for life cycle of N_{SC}; and

f_{fn}, τ_{fn} = normal and shear fatigue strength of the detail for 5 × 10^6 cycles, for the detail category (*see* Table 26).

NOTE — The arrow indicates the location and direction of the stresses acting in the basic material for which the stress range is to be calculated on a plane normal to the arrow.

19.5 Fatigue Assessment

19.5.1 The design fatigue strength for N_{SC} life cycles (f_{fd}, τ_{fd}) may be obtained from the standard fatigue strength for N_{SC} cycles by multiplying with correction factor, μ_r, for thickness, as mentioned in **19.2.1** and dividing by partial safety factor given in Table 25.

19.5.2 *Stress Limitations*

19.5.2.1 The maximum (absolute) value of the normal and shear stresses shall never exceed the elastic limit (f_y, τ_y) for the material under cyclic loading.

19.5.2.2 The maximum stress range shall not exceed 1.5 f_y for normal stresses and 1.5 $f_y/\sqrt{3}$ for the shear stresses under any circumstance.

19.5.2.3 *Constant stress range*

The actual normal and shear stress range f and τ at a point of the structure subjected to N_{SC} cycles in life shall satisfy:

$$f \leq f_{fd} = \mu_r f_f / \gamma_{mft}$$

$$\tau \leq \tau_{fd} = \mu_r \tau_f / \gamma_{mft}$$

where

f_f, τ_f = normal and shear fatigue strength ranges for the actual life cycle, N_{SC}, obtained from **19.4**;

μ_r = correction factor (*see* **19.2.1**); and

γ_{mf} = partial safety factor against fatigue failure, given in Table 25.

19.5.2.4 *Variable stress range*

Fatigue assessment at any point in a structure, wherein variable stress ranges f_i or τ_i for n_i number of cycles (i =1 to r) are encountered, shall satisfy the following:

a) For normal stress (f):

$$\frac{\sum_{i=1}^{r_5} n_i f_i^3}{5\times10^6\left(\mu_r f_{fn}/\gamma_{mft}\right)^3} + \frac{\sum_{j=r_5}^{r} n_j f_j^5}{5\times10^6\left(\mu_r f_{fn}/\gamma_{mft}\right)^5} \leq 1.0$$

b) For shear stresses (τ):

$$\sum_{i=0}^{r} n_i \tau_i^5 \leq 5 \times 10^6 (\mu_r \tau_{fn}/\gamma_{mft})$$

Where r_5 is the summation upper limit of all the normal stress ranges (f_i) having magnitude lesser than ($\mu_r f_{fn}/\gamma_{mft}$) for that detail and the lower limit of all the normal stress ranges (f_j) having magnitude greater than ($\mu_r f_{fn}/\gamma_{mft}$) for the detail. In the above summation all normal stress ranges, f_i, and shear stress ranges τ_i having magnitude less than $0.55\mu_r f_{fn}$, and $0.55\mu_r \tau_{fn}$, respectively may be disregarded.

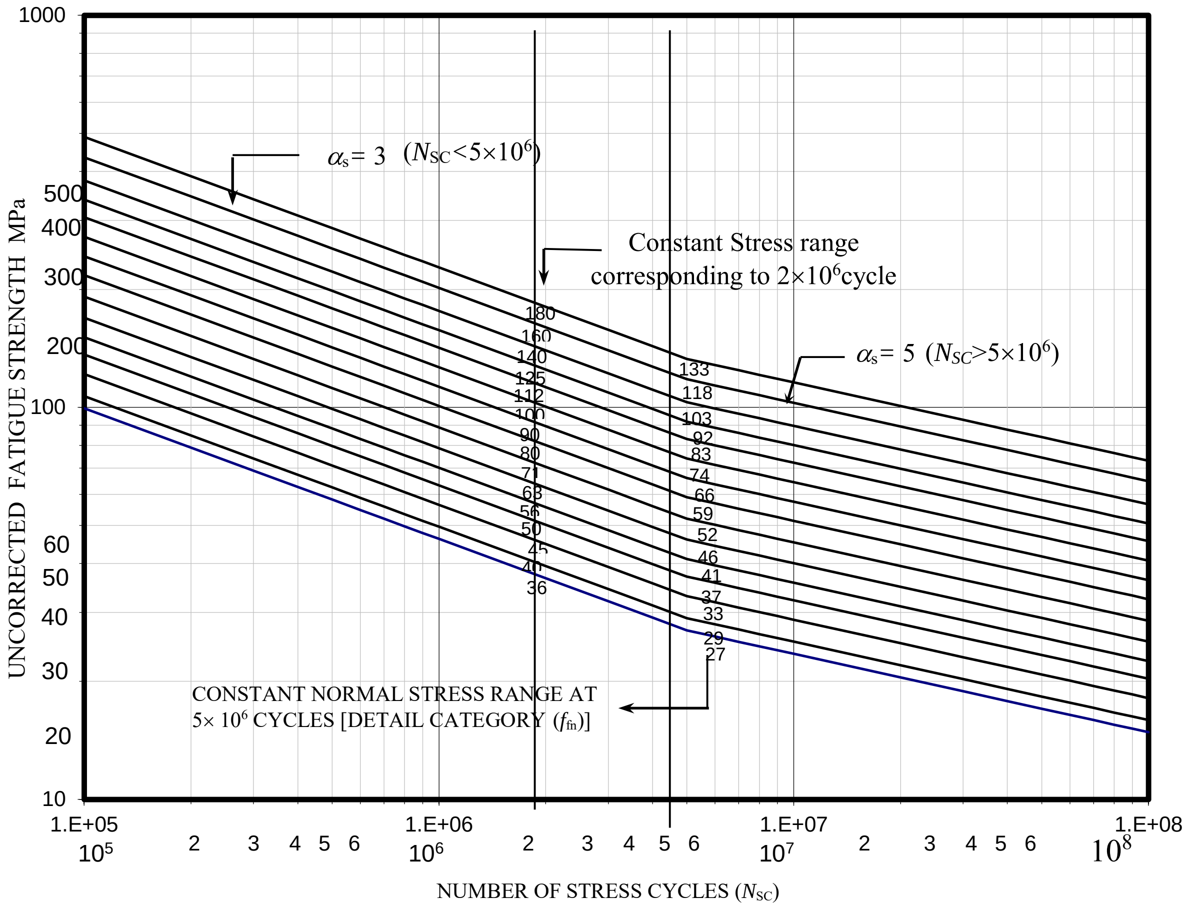

FIG. 22 S-N CURVE FOR NORMAL STRESS

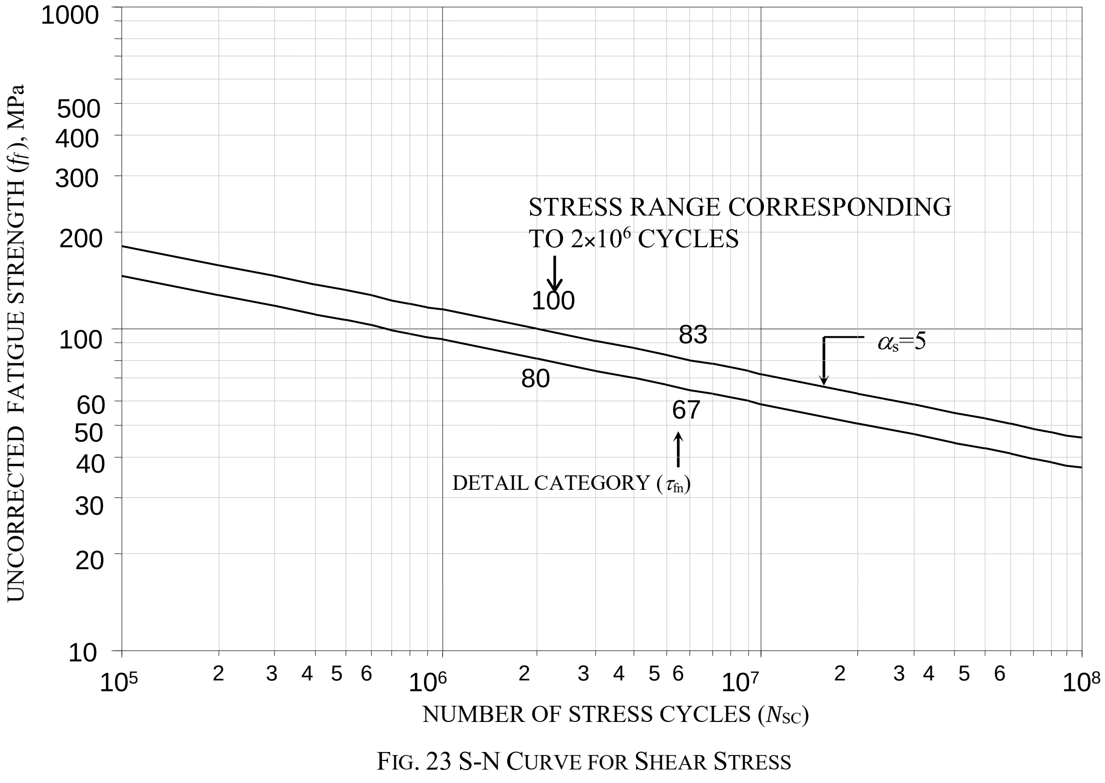

FIG. 23 S-N CURVE FOR SHEAR STRESS

20 DESIGN ASSISTED BY TESTING

20.1 Need for Testing

Testing of structures, members or components of structures is not required when designed in accordance with this standard. Testing may be accepted as an alternative to calculations or may become necessary in special circumstances.

Testing of a structural system, member or component may be required to assist the design in the following cases:

a) when the calculation methods available are not adequate for the design of a particular structure, member or component, testing shall be undertaken in place of design by calculation or to supplement the design by calculation;

b) where rules or methods for design by calculation would lead to uneconomical design, experimental verification may be undertaken to avoid conservative design;

c) when the design or construction is not entirely in accordance with sections of this standard, experimental verification is recommended;

d) when confirmation is required on the consistency of production of material, components, members or structures originally designed by calculations or testing; and

e) when the actual performance of an existing structure capacity is in question, testing shall be used to confirm it.

20.1.1 Testing of structural system, member or component shall be of the following categories:

a) *Proof testing* — The application of test loads to a structure, sub-structure, member or connection to ascertain the structural characteristics of only that specific unit; and

b) *Prototype testing* — Testing of structures, sub-structures, members or connections is done to ascertain the structural characteristics of a class of such structures, sub-structures members or connection, which are nominally identical to the units tested.

20.2 Types of Test

20.2.1 *Acceptance Test*

This is intended as a non-destructive test for confirming structural performance. It should be recognized that the loading applied to certain structures might cause permanent distortions. Such effects do not necessarily indicate structural failure in acceptance test. However, the possibility of their occurrence should be agreed to before testing.

The load for acceptance test, $F_{\text{test,a}}$ shall be determined from:

$$F_{\text{test,a}} = (\text{Self weight}) + (1.15 \times \text{Remainder of the permanent load}) + (1.25 \times \text{Variable load})$$

The assembly shall satisfy the following criteria:

a) it shall demonstrate substantially linear behaviour under test loading; and

b) on removal of the test load, the residual deflection shall not exceed 20 percent of the maximum-recorded deflection.

If the above criteria are not satisfied the test may be repeated one more time only, when the assembly shall satisfy the following criteria:

a) it shall demonstrate substantially linear behaviour on the second application of test loading; and

b) corresponding recorded residual deflection in the second test shall not exceed 10 percent of the maximum deflection during the test.

20.2.2 *Strength Test*

Strength test is used to confirm the calculated resistance of a structure or component. Where a number of items are to be constructed to a common design, and one or more prototypes are tested to confirm their strength, the others may be accepted without any additional test, provided they are similar in all relevant respects to the prototype.

Before carrying out the strength test, the specimen should first be subjected to and satisfy the acceptance test. Since the resistance of the assembly under test depends on the material properties, the actual yield strength of all the steel materials in the assembly shall be determined from coupon {test piece as defined in the accepted standard [C-6A(7)]} tests. The mean value of the yield strength, f_{ym}, taken from such tests shall be determined with due regard to the importance of each element in the assembly. The strength test load $F_{test,s}$ (including self weight) shall be determined from:

$$F_{test,s} = \gamma_{mi} F_d (f_{ym} / f_y)$$

where

F_d = factored design load for the ultimate limit state;

f_y = characteristic yield stress of the material as assumed in the design; and

γ_{mi} = partial safety factor for the type of failure, as prescribed in this standard.

At this load there shall be no failure by buckling or rupture of any part of the structure or component tested. On removal of the test load, the deflection should decrease by at least 20 percent of the maximum deflection at $F_{test,s}$.

20.2.3 *Test to Failure* (*Ultimate Strength Test*)

The objective of a test to failure is to determine the design resistance from the ultimate resistance. In this situation it is still desirable to carry out the acceptance and strength tests, before test to failure.

Not less than three tests shall be carried out on nominally identical specimens. An estimate should be made of the anticipated ultimate resistance as a basis for such tests. During a test to failure, the loading shall first be applied in increments up to the strength test load. Subsequent load increments shall then be determined from consideration of the principal load deflection plot. The test load resistance, $F_{test.R}$ shall be determined as that load at which the specimen is unable to sustain any further increase in load. At this load, gross permanent distortion is likely to have occurred and in some cases such large gross deformation may define the test limit. If the deviation of any individual test result exceeds 10 percent of the mean value obtained for all the three tests, at least three more tests shall be carried out. When the deviation from the mean does not exceed 10 percent of the mean, the design resistance may be evaluated as given below:

a) When the failure is ductile, the design resistance, F_d may be determined from:

$$F_d = 0.9 F_{test,Min} (f_y / f_{ym}) / \gamma_{m0}$$

where

$F_{test,Min}$ = minimum test result from the tests to failure;

f_{ym} = average yield strength as obtained from the material tests; and

f_y = characteristic yield stress of the grade of steel.

In the case of a sudden (brittle) rupture type failure, the design resistance may be determined from:

$$F_d = 0.9 F_{test,Min} (f_u / f_{um}) / \gamma_{ml}$$

where

f_u = characteristic ultimate stress of the grade of steel used; and

f_{um} = average ultimate tensile strength of the material obtained from tests.

b) In the case of a sudden (brittle) buckling type failure, the design resistance shall be determined from:

$$F_d = 0.75 F_{test,Min} (f_y / f_{ym}) / \gamma_{m0}$$

c) In ductile buckling type failure in which the relevant slenderness λ can be reliably assessed, the design resistance may be determined from:

$$F_d = 0.9 F_{test,Min} \left[(\chi f_y / \chi_m f_{ym}) / \gamma_{m0} \right]$$

where

χ = reduction factor for the relevant buckling curve; and

χ_m = value of χ when the yield strength is f_{ym}.

20.2.4 *Check Tests*

Where a component or assembly is designed on the basis of strength tests or tests to failure and a production run is carried out of such items, an appropriate number of samples (not less than two) shall be selected from each production batch at random for check tests.

20.2.4.1 The samples shall be carefully examined to ensure that they are similar in all respects to the prototype tested, particular attention being given to the following:

a) Dimensions of components and connections;

b) Tolerance and workmanship; and

c) Quality of steel used, checked with reference to mill test certificates.

20.2.4.2 Where it is not possible to determine either the variations or the effect of variations from the prototype, an acceptance test shall be carried out as a check test.

20.2.4.3 In this check test, the deflections shall be measured at the same positions as in the acceptance test of the prototype. The maximum measured deflection shall not exceed 120 percent of the deflection recorded during the acceptance test on the prototype and the residual deflection should not be more than 105 percent of that recorded for the prototype.

20.3 Test Conditions

Followings are the conditions for the test:

a) loading and measuring devices shall be calibrated in advance;

b) the design of the test rig shall be such that:

   1) loading system adequately simulates the magnitude and distribution of the loading;

   2) it allows the specimen to perform in a manner representative of service conditions;

   3) lateral and torsional restraint, if any, should be representative of those in service;

   4) specimen should be free to deflect under load according to service condition;

   5) loading system shall be able to follow the movements of the specimen without interruption or abnormal restraints; and

   6) inadvertent eccentricities at the point of application of the test loads and at the supports are avoided.

c) test load shall be applied to the unit at a rate as uniform as practicable;

d) deflections should be measured at sufficient points of high movements to ensure that the maximum value is determined;

e) if the magnitude of stresses in a specimen is to be determined, the strain at the desired location may be measured and the corresponding stress calculated; and

f) prior to any test, preliminary loading (not exceeding the characteristic values of the relevant loads) may be applied and then removed, in order to set the test specimen on to the test rig.

20.4 Test Loading

20.4.1 Where the self-weight of the specimen is not representative of the actual permanent load in service, allowance for the difference shall be made in the calculation of test loads to be applied.

20.4.2 On the attainment of maximum load for either acceptance or strength tests, this load shall be maintained as given below. Reading of load and deflection shall be taken at intervals of 15 min and the loading shall be maintained constant until there is no significant increase in deflection during a 15 min period or until at least 1 h has elapsed after application of maximum load.

20.4.3 The test load shall be equal to the design load for the relevant limit state in proof testing.

20.4.4 The test load in prototype testing shall be equal to the design load for the relevant limit state as multiplied by the appropriate factor given in Table 27.

20.5 Criteria for Acceptance

20.5.1 *Acceptance for Strength*

The test structure, sub-structure, member or connection shall be deemed to comply with the requirements for strength if it is able to sustain the strength test load as required in **20.4.2**.

It shall then be inspected to determine the nature and extent of any damage incurred during the test. The effects of the damage shall be considered and if necessary appropriate repairs to the damaged parts carried out.

20.5.2 *Acceptance for Serviceability*

The maximum deformation of the structure or member under the serviceability limit state test load shall be within the serviceability limit values appropriate to the structure.

21 DURABILITY

21.1 General

A durable steel structure is one that performs satisfactorily the desired function in the working environment under the anticipated exposure condition during its service life, without deterioration of the cross sectional area and loss of strength due to corrosion.

The material used, the detailing, fabrication, erection and surface protection measures should all address the corrosion protection and durability requirements.

21.2 Requirements for Durability

21.2.1 *Shape, Size, Orientation of Members, Connections and Details*

The design, fabrication and erection details of exposed structures should be such that good drainage of water is ensured. Standing pool of water, moisture accumulation and rundown of water for extended duration shall be avoided.

The details of connections should ensure that:

a) all exposed surfaces are easily accessible for inspection and maintenance; and

b) all surfaces, not so easily accessible are completely sealed against ingress of moisture.

21.2.2 *Exposure Condition*

21.2.2.1 *General environment*

The general environment, to which a steel structure is exposed during its working life is classified into five levels of severity, as given in Table 28.

21.2.2.2 *Abrasion*

Specialist literature may be referred for durability of surfaces exposed to abrasive action as in machinery, conveyor belt support system, storage bins for grains or aggregates.

21.2.2.3 *Exposure to sulphate attack*

Appropriate coatings may be used when surfaces of structural steel are exposed to concentration of sulphates (SO_3) in soil, ground water, etc.

When exposed to very high sulphate concentrations of more than 2 percent in soil and 5 percent in water, some form of lining such as polyethylene, polychloroprene sheet or surface coating based on asphalt, chlorinated rubber, epoxy or polymethane material should be used to completely avoid access of the solution to the steel surface.

21.2.3 *Corrosion Protection Methods*

The methods of corrosion protection are governed by actual environmental conditions as specified in good practices [C-6A(43)]. The main corrosion protection methods are given below:

a) Controlling the electrode potential;

b) Inhibitors; and

c) Inorganic/metal coatings or organic/paint systems.

Table 28 Environmental Exposure Conditions

(*Clause* 21.2.2.1)

Sl No. (1)	Environmental Classifications (2)	Exposure Conditions (3)
i)	Mild	Surfaces normally protected against exposure to weather or aggressive condition as in interior of buildings, except when located in coastal areas
ii)	Moderate	Structural steel surfaces: a) exposed to condensation and rain; b) continuously under water; c) exposed to non-aggressive soil/groundwater; and d) sheltered from saturated salt air in coastal areas
iii)	Severe	Structural steel surfaces: a) exposed to severe frequent rain; b) exposed to alternate wetting and drying; c) severe condensation; d) completely immersed in sea water; and e) exposed to saturated salt air in coastal area
iv)	Very severe	Structural steel surface exposed to: a) sea water spray; b) corrosive fumes; and c) aggressive sub-soil or ground water.
v)	Extreme	Structural steel surfaces exposed to: a) tidal zones and splash zones in the sea; and b) aggressive liquid or solid chemicals

21.2.4 *Surface Protection*

21.2.4.1 In the case of mild exposure, a coat of primer after removal of any loose mill scale may be adequate. As the exposure condition becomes more critical, more elaborate surface preparations and coatings become necessary. In case of extreme environmental classification, protection shall be as per specialist literature. Table 29 gives guidance to protection of steelwork for different desired lives.

21.2.4.2 Steel surfaces shall be provided with at least one coat of primer immediately after its surface preparation, such as by sand blasting to remove all mill scale and rust and to expose the steel.

21.2.4.3 Steel without protective coating shall not be stored for long duration in outdoor environment.

21.2.4.4 Surfaces to transfer forces by friction as in HSFG connections shall not be painted. However, it shall be ensured that moisture is not trapped on such surfaces after pre-tensioning of bolts by proper protective measures.

21.2.4.5 Members to be assembled by welding shall not be pre-painted at regions adjacent to the location of such welds. However, after welding, appropriate protective coatings shall be applied in the region, as required by the exposure conditions. If the contact surfaces cannot be properly protected against ingress of moisture by surface coating, they may be completely sealed by appropriate welds.

21.2.4.6 Pre-painted members shall be protected against abrasion of the coating during transportation, handling and erection.

21.2.5 *Special Steels*

Steels with special alloying elements and production process to obtain better corrosion resistance may be used as per specialist literature.

22 FIRE RESISTANCE

22.1 Requirements

The requirements shall apply to steel building elements designed to exhibit a required fire-resistance level (FRL) as per the relevant specifications. The provisions of this section are quite rudimentary and simplistic. Specialist literature for design of steel structures for fire resistance and design based on testing may be necessary for a more comprehensive design of steel buildings to resist fire.

22.1.1 For protected steel members and connections, the thickness of protection material (h_i) shall be greater than or equal to that required to give a period of structural adequacy (PSA) greater than or equal to the required FRL.

22.1.2 For unprotected steel members and connections, the exposed surface area to mass ratio (k_{sm}) shall be less than or equal to that required to give a PSA equal to the required FRL.

22.2 Fire Resistance Level

The required FRL shall be as prescribed in Part F 'Fire and Life Safety' of this NBCS and relative fire norms/ standards, as appropriate or in building specifications or as required by the user or the city ordinance. The FRL specified in terms of the duration (in min) of standard fire load without collapse depends upon;

a) the purpose for which structure is used; and

b) the time taken to evacuate in case of fire.

22.3 Period of Structural Adequacy (PSA)

22.3.1 The calculation of PSA involves:

a) calculation of the strength of the element as a function of temperature of the element and the determination of limiting temperature;

b) calculation of the thermal response of the element, that is calculation of the variation of the temperature of the element or the parts of the element with time, when exposed to fire; and

c) determination of PSA at which the temperature of the element or parts of the element reaches the limiting temperature.

22.3.2 *Determination of Period of Structural Adequacy*

The period of structural adequacy (PSA) shall be determined using one of the following methods:

a) *By calculation*:

   1) determining the limiting temperature of the steel (T_l) in accordance with 22.5; and

   2) determining the PSA as the time (t) (in min) from the start of the test to the time at which the limiting steel temperature is attained, in accordance with 22.6 for protected members and 22.7 for unprotected members.

b) By direct application of a single test in accordance with 22.8; or

c) By calculation of the temperature of the steel member by using a rational method of analysis confirmed by test data or by methods available in specialist literature.

22.4 Variation of Mechanical Properties of Steel with Temperature

22.4.1 *Variation of Yield Stress with Temperature*

The influence of temperature on the yield stress of steel shall be taken as follows for structures of mild steels and high strength low alloy steels:

$$\frac{f_y(T)}{f_y(20)} = \frac{905 - T}{690} \leq 1.0$$

where

$f_y(T)$ = yield stress of steel at T °C;

$f_y(20)$ = yield stress of steel at 20 °C (room temperature); and

T = temperature of the steel, in °C.

This relationship is shown by curve 1 in Fig. 24.

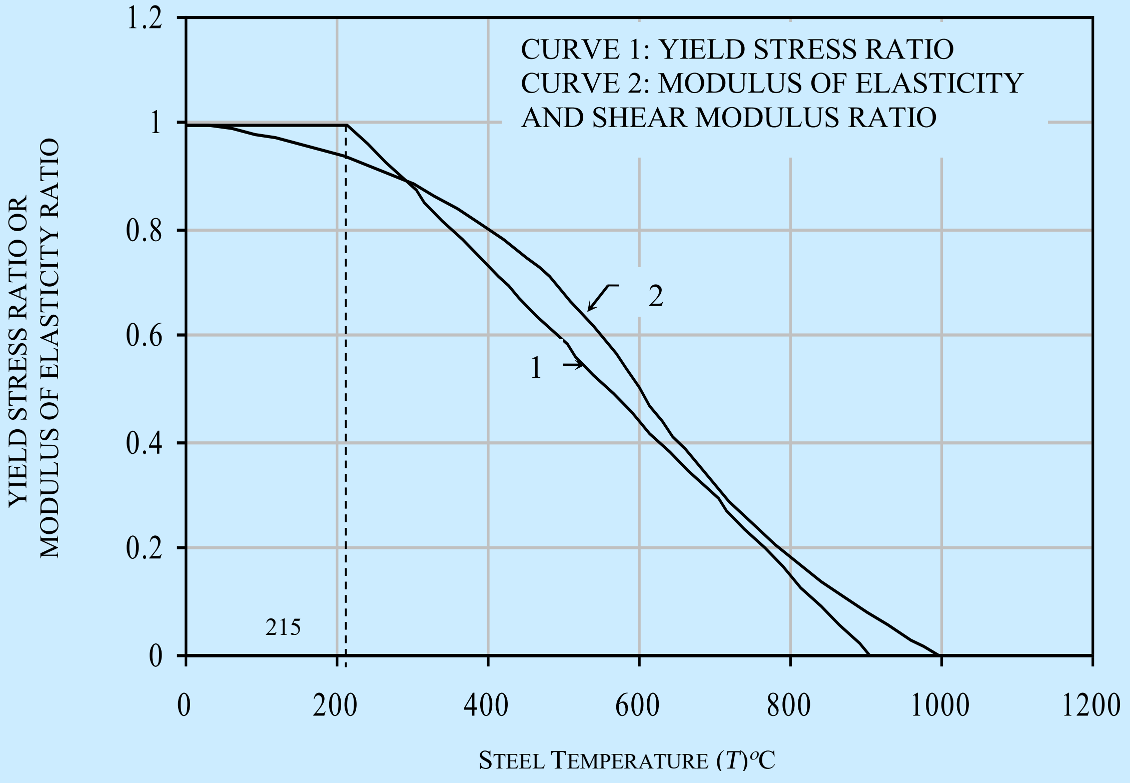

FIG. 24 VARIATION OF MECHANICAL PROPERTIES OF STEEL WITH TEMPERATURE

For temperature less than 215 °C no reduction in the yield stress need to be considered.

22.4.2 *Variation of Modulus of Elasticity and Shear Modulus with Temperature*

The influence of temperature on the modulus of elasticity shall be taken as follows for structures of mild steels and high strength low alloy steels:

$$\frac{E(T)}{E(20)} \; and \; \frac{G(T)}{G(20)} = 1.0 + \left[\frac{T}{2000\left[ln\left(\frac{T}{1\,100}\right)\right]}\right] \text{ when } 0\,°\text{C} < T \leq 600\,°\text{C}$$

$$= \frac{690\left(1 - \frac{T}{1000}\right)}{T - 53.5} \quad \text{when} \quad 600\,°\text{C} < T \leq 1000\,°\text{C}$$

where

$E(T)$ = Modulus of elasticity of steel at T °C, and

E (20) = Modulus of elasticity of steel at 20 °C (room temperature).

G (T) = Shear Modulus of steel at T °C, and

G (20) = Shear Modulus of steel at 20 °C (room temperature).

This relationship is shown by curve 2 in Fig. 24.

22.4.3 For special steel with higher temperature resistance, such as TMCP steels, the manufacturer's recommendation shall be used to obtain the variation of yield strength and modulus of elasticity of steel with temperature.

22.5 Limiting Steel Temperature

The limiting steel temperature (T_l), in °C, in the case of structural steels, shall be calculated by substituting f_y, f_u, E, and G values with $f_y(T)$, $f_y(T)$, $E(T)$, and $G(T)$ calculated in accordance with **22.4**, respectively in **13**, **14**, **15**, and **16** to calculate the design capacity of the member as a function of steel temperature. The limiting temperature (T_l) will be the temperature at which the design capacity is equal to the design action on the member.

The design action under fire shall consider the following:

a) Loads as per the load combinations for fire conditions given in Table 4;

b) Effects of restraint to expansion of the elements during fire; and

c) Reduced bond likely under fire.

Limiting steel temperature for special steels may be appropriately calculated using the thermal characteristics of the material obtained from the supplier of the steel.

22.6 Temperature Increase with Time in Protected Members

22.6.1 The time (t) at which the limiting temperature (T_l) is attained shall be determined by calculation on the basis of a suitable series of fire tests in accordance with **22.6.2** or from the results of a single test in accordance with **22.6.3**.

22.6.1.1 For beams and for all members with a four-sided fire exposure condition, the limiting temperature (T_l) shall be taken as the average of all of the temperatures measured at the thermocouple locations on all sides.

22.6.1.2 For columns with a three-sided fire exposure condition, the limiting temperature (T_l) shall be taken as the average of the temperatures measured at the thermocouple locations on the face farthest from the wall. Alternatively, the temperatures from members with a four-sided fire exposure condition and having the same surface area to mass ratio may be used.

22.6.2 *Temperature Based on Test Series*

Calculation of the variation of steel temperature with time shall be by interpolation of the results of a series of fire tests using the regression analysis equation specified in **22.6.2.1**, subject to the limitations and conditions of **22.6.2.3**.

22.6.2.1 *Regression analysis*

The relationship between temperature (T) and time (t) for a series of tests on a group shall be calculated by least-square regression as follows:

$$t = k_0 + k_1 h_i + k_2 \left(\frac{h_i}{k_{sm}} \right) + k_3 T + k_4 h_i T + k_5 \left(\frac{h_i T}{k_{sm}} \right) + k_6 \left(\frac{T}{k_{sm}} \right)$$

where

h_i = thickness of fire protection material, in mm;

k_0 to k_6 = regression coefficients from test data (*see* **22.6.2.2**);

k_{sm} = exposed surface area to mass ratio, in 10^3 mm^2/kg;

t = time from the start of the test, in min; and

T = steel temperature, in 0 °C obtained from test as given in **22.6.1**, $T > 250$ °C.

22.6.2.2 *In lieu of* test results, the values for coefficients in Table 30 may be used in the equation **22.6.2.1** when the test satisfies the conditions specified in **22.6.2.3**.

Table 30 Regression Coefficients, k

(*Clause* 22.6.2.2)

Sl No. (1)	k_0 (2)	k_1 (3)	k_2 (4)	k_3 (5)	k_4 (6)	k_5 (7)	k_6 (8)
i)	– 25.90	1.698	– 13.71	0.030 0	0.000 5	0.514 4	6.633

22.6.2.3 *Limitations and conditions on use of regression analysis*

Test data to be utilized in accordance with **22.6.2.1**, shall satisfy the following:

a) Steel members shall be protected with board, sprayed blanket or similar insulation materials having a dry density less than 1000 kg/m^3;

b) All tests shall incorporate the same fire protection system;

c) All members shall have the same fire exposure condition;

d) Test series shall include at least nine tests;

e) Test series may include prototypes which have not been loaded provided that stickability has been demonstrated; and

f) All members subject to a three-sided fire exposure condition shall be within a group in accordance with **22.9**.

The regression equation obtained for one fire protection system may be applied to another system using the same fire protection material and the same fire exposure condition provided that stickability has been demonstrated for the second system.

A regression equation obtained using prototypes with a four-sided fire exposure condition may be applied to a member with a three-sided fire exposure condition provided that stickability has been demonstrated for the three-sided case.

22.6.3 *Temperature Based on Single Test*

The variation of steel temperature with time measured in a standard fire test may be used without modification provided:

a) fire protection system is the same as the prototype;

b) fire exposure condition is the same as the prototype;

c) fire protection material thickness is equal to or greater than that of the prototype;

d) surface area to mass ratio is equal to or less than that of the prototype; and

e) where the prototype has been submitted to a standard fire test in an unloaded condition, stickability has been separately demonstrated.

22.6.4 *Parameters of Importance in the Standard Fire Test*

a) Specimen type, loading, configuration;

b) Exposed surface area to mass ratio;

c) Insulation type, thermal properties and thickness; and

d) Moisture content of the insulation material.

22.7 Temperature Increase with Time in Unprotected Members

The time (t) at which the limiting temperature (T_l) is attained shall be calculated using the following equations:

a) Three-sided fire exposure condition:

$$t = -5.2 + 0.022\ 1\,T + \left(\frac{0.433T_l}{k_{\mathrm{sm}}}\right)$$

b) Four-sided fire exposure condition:

$$t = -4.7 + 0.0263\ T + \left(\frac{0.213T_l}{k_{\mathrm{sm}}}\right)$$

where

k_{sm} = exposed surface area to mass ratio, 2×10^3 mm^2/kg $\leq k_{\mathrm{sm}} \leq 35\times10^3$ mm^2/kg;

t = time, in min, from the start of the test; and

T = steel temperature, in ºC, 500 ºC $\leq T \leq$ 750 ºC.

For temperatures below 500 ºC, linear interpolation shall be used, based on the time at 500 ºC and an initial temperature of 20 °C at t equals 0.

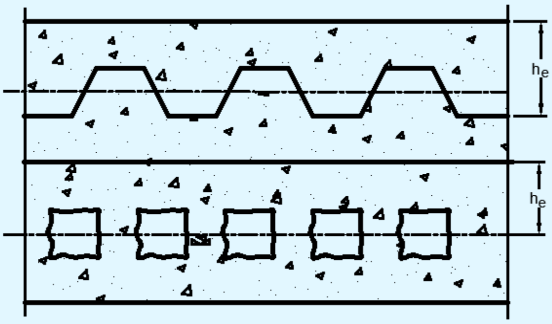
22.8 Determination of PSA from a Single Test

The period of structural adequacy (PSA) determined from a single test may be applied without modification provided:

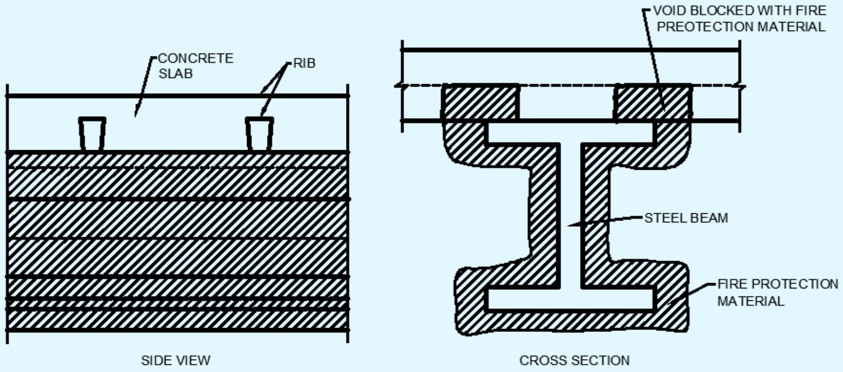
a) conditions, specified in **22.6.3** are satisfied;

b) conditions of support are the same as the prototype and the restraints are not less favourable than those of the prototype; and

c) ratio of the design load for fire to the design capacity of the member is less than or equal to that of the prototype.



23 A EFFECTIVE THICKNESS



23 B BLOCKING OF RIB VOIDS

FIG. 25 THREE SIDED FIRE EXPOSURE CONDITION REQUIREMENTS

22.9 Three-sided Fire Exposure Condition

Members subject to a three-sided fire exposure condition shall be considered in separate groups unless the following conditions are satisfied:

a) the characteristics of the members of a group as given below, shall not vary from one another by more than:

1) Concrete density: $\left(\frac{\text{highest in group}}{\text{lowest in group}}\right) \leq 1.25$; and

2) Effective thickness (h_e): $\left(\frac{\text{largest in group}}{\text{smallest in group}}\right) \leq 1.25$

where the effective thickness (h_e) is equal to the cross sectional area excluding voids per unit width, as shown in Fig. 25 (a).

b) Rib voids shall either be:

1) all open; or

2) all blocked as shown in Fig. 25 (b).

c) Concrete slabs may incorporate permanent steel deck formwork.

22.10 Special Considerations

22.10.1 *Connections*

Connections shall be protected with the maximum thickness of fire protection material required for any of the members framing into the connection to achieve their respective fire-resistance levels. This thickness shall be maintained over all connection components, including bolt heads, welds and splice plates.

22.10.2 *Web Penetrations*

The thickness of fire protection material at and adjacent to web penetrations shall be the greatest of that required, when:

a) area above the penetration is considered as a three-sided fire exposure condition (k_{sm1}) (*see* Fig. 26);

b) area below the penetration is considered as a four-sided fire exposure condition (k_{sm2}) (*see* Fig. 26); and

c) section as a whole is considered as a three-sided fire exposure condition (k_{sm}) (*see* Fig. 26).

This thickness shall be applied over the full beam depth and shall extend on each side of the penetration for a distance at least equal to the beam depth and not less than 300 mm.

22.11 Fire Resistance Rating

The fire resistance rating of various building components such as walls, columns, beams, and floors are given in Table 31 and Table 32. Fire damage assessment of various structural elements of the building and adequacy of the structural repairs can be done by the fire resistance rating for encased steel column and beam (*see* Table 31 and Table 32).

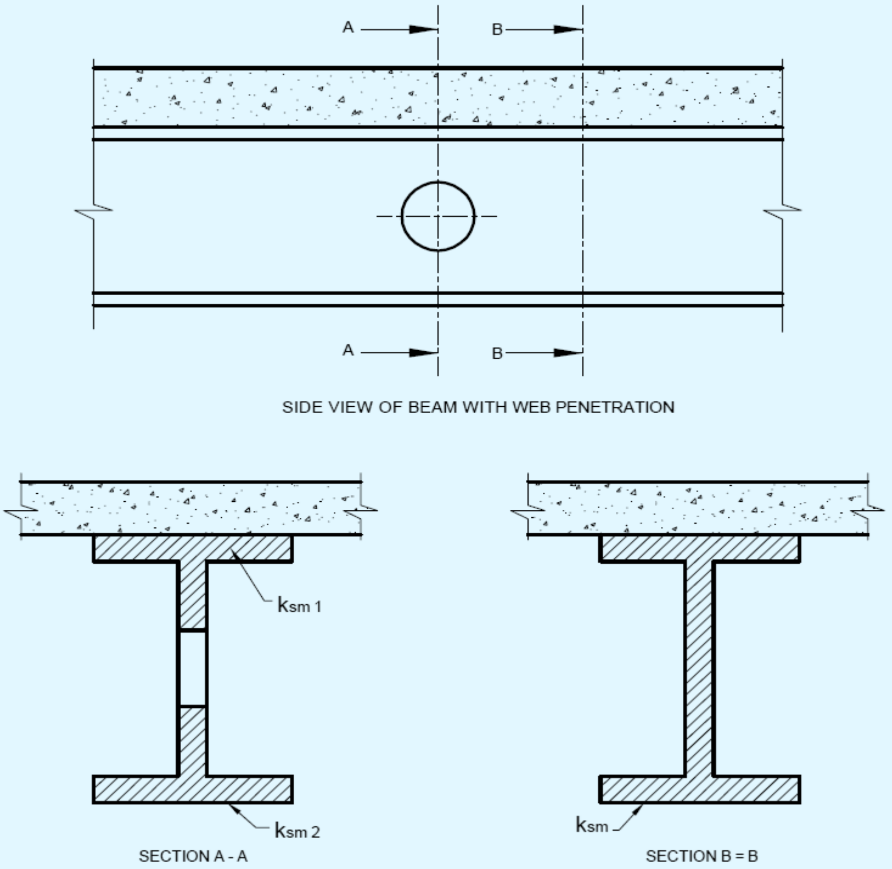


FIG. 26 WEB PENETRATION

Table 31 Encased Steel Columns, 203 mm × 203 mm (Protection Applied on Four Sides)

		½ h	1 h	1½ h	2 h	3 h	4 h
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
i)	Hollow protection (without an air cavity beneath the lower flanges):						
	a) Metal lathing with trowelled lightweight aggregate gypsum plaster[1]	13	13	15	20	25	—
	b) Plasterboard with 1.6 mm wire binding at 100 mm pitch, finished with lightweight aggregate gypsum plaster less than the thickness specified[2]:						
	1) 9.5 mm plaster board; and	10	10	15	—	—	—
	2) 19 mm plaster board	10	10	13	20	—	—
	c) Asbestos insulating boards, thickness of board:						
	1) single thickness of board, with 6 mm cover fillets at transverse joints	—	—	19	25	—	—
	2) two layers, of total thickness	—	—	—	—	38	50
ii)	Hollow protection (with an air cavity below the lower flange):						
	a) Asbestos insulating board screwed to 25 mm asbestos battens	9	12	—	—	—	—
iii)	Solid protections:						
	a) Concrete, not leaner than 1 : 2 : 4 mix (unplastered):						
	1) concrete not assumed to be load bearing, reinforced [3]; and	25	25	25	25	50	75
	2) concrete assumed to be load bearing	50	50	50	50	75	75
	b) Lightweight concrete, not leaner than 1 : 2 : 4 mix (unplastered) [4]	25	25	25	25	40	60

---

[1] So fixed or designed, as to allow full penetration for mechanical bond.

[2] Where wire binding cannot be used, expert advice should be sought regarding alternative methods of support to enable the lower edges of the plasterboard to be fixed together and to the lower flange, and for the top edge of the plasterboard to be held in position.

[3] Reinforcement shall consist of steel binding wire not less than 2.3 mm in diameter, or a steel mesh weighing not less than 0.5 kg/m^2. In concrete protection, the spacing of that reinforcement shall not exceed 200 mm in any direction.

[4] Concrete not assumed to be load bearing, reinforced.

23 SUSTAINABLE STEEL CONSTRUCTION

23.1 General

This Chapter specifies general requirements and practices for achieving environmentally sustainable steelwork building construction. This supplements the requirements of the other chapters of this specification.

23.2 Principles of Sustainable Steel Construction

a) The structural steel design should provide a structure capable of fulfilling its intended function while sustaining the specified loads for its intended life with due regard to sustainability, robustness, economy, health and safety. Any expected change in the intended function during its life time should also be considered;

b) In environmentally sustainable construction all stake holders should consider the broader and holistic implications of the decision, which include the whole life cycle sustainability, impacts on other parts of the building and the project, externalities, maintenance, societal cost and consequences, without impinging upon safety and efficiency of the structure;

c) All parties in the supply chain for structural steelwork should take practical steps to reduce the greenhouse gas emissions of the processes over which they have control, thus contributing to sustainable construction. Further, construction operations should avoid/minimize polluting the environment with dust, wastewater, chemicals and leaching debris;

d) Steelmaking should make full use of available secondary material (scrap) globally;

e) Structural steelwork should be designed, detailed, and constructed to minimize material use and wastage of material and facilitate its recovery for reuse at its end-of-life, as a part of the circular economy, to the extent that this is reasonably practicable; and

f) The design should consider practical aspects of construction to avoid repair and rework.

23.3 Specification Requirements from Supply Chain Members

23.3.1 *Requirements from Employer*

a) Appointment of key contractors (Architects, contractors for Steel work, cladding, glazing, Mechanical, Electrical, coating systems, etc) as early as practical to ensure decisions are fully coordinated;

b) Maximization of structural zones that facilitate lean and efficient designs; and

c) Flexibility in design, if use of reclaim materials is considered.

23.3.2 *Requirements from Main Contractor*

a) Early engagement of supply chain and subcontractors with emphasis on sustainability; and

b) Judicious site planning to receive material, use of labour and location of machinery for efficient handling and construction.

23.3.3 *Requirements from the Engineering Group*

a) Design for material efficiency, equipment efficiency, and minimal embodied energy and longevity;

b) Consider holistically the environmental impact implication of temporary works and supports;

c) Design with inbuilt flexibility and adaptability;

d) Consider the economic and environmental implications of the type of connections chosen; and

e) Assess the requirement of protective treatment against corrosion and fire to minimize the life time maintenance and avoid over-specification.

23.3.4 *Requirements from Steelwork Contractor*

Establish a carbon reduction plan in steelwork. This may include use of low carbon emission transport, maximize the steelwork loads, optimizing haulage routes, minimizing empty runs, etc.

23.4 Sustainable Design

23.4.1 *General*

The environmental impacts associated with steelwork building construction be greatly reduced during the design process by:

a) reducing the material in the structure;

b) minimizing fabrication, and avoidance of maintenance during service life; and

c) Identifying environmental improvements at the conceptual design stage requires the involvement of all the stakeholders such as architects, steelwork contractor during all design stages. Collaborative design processes result in:

   1) materials being used more efficiently;

   2) fewer on-site changes; and

   3) reduced environmental impacts.

Greenhouse gas or carbon emissions currently being the priority, action is required by all parts of the supply chain for the sector to decarbonize in line with global targets. This includes supply-side measures, in particularly decarbonizing steel-making and also demand-side measures including more efficient design and design for longevity, deconstruction and reuse.

Greenhouse gas emission should be based on life cycle assessment, which should include emissions in material manufacturing, transport, fabrication, erection, finishing, commissioning, maintenance during life and finally at the end of useful life deconstruction and disposal of the materials as waste or through recycling and reuse.

Further, environmentally friendly designs should be implemented in the construction projects and pollution of the environment during the process of construction should be avoided, if not minimized.

23.4.2 *Minimizing Material Consumption through Design*

Minimizing material consumption through design may be achieved by:

a) Avoiding over-specification of design loads;

b) Optimizing spans and grids: and adapting the building layout to take full advantage of the structural steelwork's attributes;

c) Minimizing complex load paths and transfers in order to maximize direct load paths to ground;

d) Ensuring that structural deflection and vibration criteria, coordination zones and member depths are appropriate and allow for efficient structural solutions that avoid excessive material use;

e) Aiming to design for utilizations as close to 1.0 as practically possible, with due regard to permanent and temporary conditions;

f) Specifying higher strength steel grades in members or part of members not governed by serviceability criteria;

g) Considering key load paths, anticipated connection types and accurate loading criteria, in order to facilitate lean design principles;

h) Avoiding the over rationalization of steel member sizes to ensure efficient use of material, with due consideration of minimum economic quantities for procurement;

j) Reviewing section sizes and minimizing weight, whilst complying with safe methods of erection and fire protection requirements; and

k) Semi-continuous design, which assumes that the joints transfer moments from the beam to the column and allow rotation between the connected members as the load is resisted.

NOTE — Historically, steelwork design and fabrication has mainly been driven by cost however, sustainability and particularly the climate emergency, are likely to change this with more clients willing or mandated to pay more for sustainable and low carbon buildings. Reducing the carbon impact of steel structures through lean and less conservative design is technically achievable but can require more design effort and more complex fabrication.

23.4.3 *Design for Adaptability and Deconstruction*

Design engineer should review design options with the steelwork contractor that may contribute to future flexibility, adaptability, deconstruction and reuse of the building structure, such as:

a) how the building design and information records about the materials and members can facilitate future, remodelling, deconstruction and recovery for reuse and recycling;

b) ensuring accessibility to members and connections to allow for deconstruction and for ease of strengthening in the future; and

c) greater standardization of sections sizes, lengths and connections, if appropriate from adaptability and deconstruction.

23.5 Sustainable Fabrication

23.5.1 *Information Records*

A non-exhaustive checklist of information to be communicated in sustainable fabrication are given below:

a) Sustainability information to be provided to the steelwork contractor:
   1) any part of the steelwork that is to incorporate reclaimed steel products;
   2) any part of the steelwork that is to be left untreated;
   3) any details of the fire design, namely the design utilization per section size in the fire condition;
   4) any workshop waste targets;
   5) a life cycle assessment of the whole building; and
   6) any specific material sourcing requirements.

b) Sustainability information to be provided by the steelwork contractor:
   1) All relevant EPDs for the steel and other products;
   2) The embodied carbon of the fabricated steelwork;
   3) Digital records of the 'As erected' structure, which should include all condition of structures, survey, metadata, etc;
   4) Material quality and quantity data, including batch traceability for main structural members to facilitate future reuse (to be included in the operation and maintenance manual; and
   5) Documentation of evidence of an active environmental management system.

23.5.2 *Fabrication Waste Management*

Strategies for fabrication waste management include:

a) ordering directly from mills to minimize offcuts;

b) using stock lengths as ordered efficiently to minimize waste. Where possible, splice locations in steel members should be coordinated to fall within standard stock length sizes;

c) recycling and reusing steel fabrication waste, for example, off-cuts, swarf, etc;

d) considering use off-cuts of material, particularly from plate, elsewhere, for example, temporary works, connection fittings, shims, packs, rather than simply scrapping for recycling. Always prioritized reuse over recycling;

e) considering use of machines that facilitate common line cutting of fittings;

f) minimizing coating waste and coating packaging waste, by using intermediate bulk; and

g) Minimizing/ avoiding overspray of coatings should ensure operators are properly trained and the appropriate and properly maintained equipment is used.

23.5.3 *Sustainable Welding*

Strategies for sustainable welding include:

a) Avoiding low productivity processes and using automatic and semi-automatic processes with continuous wire feed, thus using material efficiently and avoiding energy waste;

b) Adopting energy-saving processes such as, inverter-based power sources instead of older regulator/rectifier-based sources, electrically powered pre-heating with temperature control instead of gas flame;

c) Minimizing pre-heat in the welding procedure specification and welding continuously to avoid the need to re-heat; and

d) Periodically reviewing welding techniques and weld procedures to make the best use of the latest advancements in welding equipment and consumables, including the selection of joint set-ups and consumables that allow for deeper penetration fillet welds to be achieved, thus potentially reducing the number of weld runs required.

23.5.4 *Sustainable Fire and Corrosion Protection Systems*

23.5.4.1 *Untreated steelwork*

Any part of the steelwork such as steelwork in a less corrosivity category, that is to be left untreated shall be identified in the Project Specification.

23.5.4.2 *Paint systems*

The protective coating system shall satisfy the requirements given in **21**.

23.5.4.3 *Intumescent systems*

For the same fire resistance water-based acrylic intumescent likely to have a lower environmental impact, when compared to solvent-based acrylic intumescent.

23.5.4.4 *Hot-dip galvanizing*

Requirements for thicker coatings, for example, by prior grit blasting, should be avoided by prior assessment of the predicted galvanized coating life and the minimum thickness required to avoid over-specification. For certain steel members (for example, with higher reactivity during galvanizing and/or larger section thickness), thicker coatings may also be achieved without grit blasting. Design and fabrication considerations for hot dip galvanizing should ensure adequate drainage and optimize material efficiency. Plan should optimize transport distances and provide direct delivery to the construction works, where feasible.

24 FABRICATION AND ERECTION

24.1 General

Tolerances for fabrication of steel structures shall conform to the accepted standard [C-6A(44)]. Tolerances for erection of steel structures shall conform to the accepted standard [C-6A(45)]. For general guidance on fabrication by welding, reference may be made to good practice [C-6A(46)].

In addition to the above, the following requirements shall also be considered:

a) The designer shall, in conjunction with the floor framing and vertical framing/stacking arrangements of the project, provide suitable tolerance mitigation measures. Such measures may include the use of slotted or oversized holes in beams and columns, use of HSFG bolts, or other appropriate detailing. These provisions need not be adopted for all members; however, they shall be judiciously incorporated in selected connections and splices to achieve the desired tolerance accommodation.

b) The structural designer shall coordinate with other disciplines, such as façade, building services, and transportation systems, and ensure that the specified tolerances for steel structures are compatible with their requirements. Where the design necessitates tolerances more stringent than those specified in the relevant codes, such requirements shall be clearly indicated in the drawings and specifications. However, in no case shall the specified tolerances be more stringent than the applicable mill rolling tolerances.

c) The designer shall specify the permissible overall horizontal and vertical tolerances for the completed building structure, in accordance with the design intent. While [C-6A(45)] specifies tolerances for erected elements, it does not address the overall geometrical accuracy of the completed structure. Therefore, the structural designer shall, in coordination with the architect and other relevant disciplines, define the acceptable limits of overall as-built accuracy. These limits shall be clearly specified so as to enable proper planning and execution by the contractor at all stages of construction.

24.2 Fabrication Procedures

24.2.1 *Straightening*

Material shall be straightened or formed to the specified configuration by methods that will not reduce the properties of the material below the values used in design. Local application of pressure at room or at elevated temperature or other thermal means may be used for straightening, provided the above is satisfied.

24.2.2 *Clearances*

The erection clearance for cleated ends of members, connecting steel to steel should preferably be not greater than 2.0 mm at each end. The erection clearance at ends of beams without web cleats should be not more than 3 mm at each end. Where for practical reasons, greater clearance is necessary, suitably designed seating should be provided.

24.2.2.1 The holes for bolts may be made as given in Table 20 of **17.2.1**, unless otherwise specified by the engineer. The hole diameter in base plates shall not exceed the anchor bolt diameter by more than 6 mm.

24.2.2.2 In friction type of connection clearance may be maintained, unless specified otherwise in the design document.

24.2.3 *Cutting*

Cutting shall be effected by sawing, shearing, cropping, machining or thermal cutting process. Shearing, cropping and gas cutting shall be clean, reasonably square, and free from any distortion. Should the inspector find it necessary, the edges shall be ground after cutting. Planning or finishing of sheared or gas-cut edges of plates or shapes shall not be required, unless specially noted on drawing or included in stipulated edge preparation for welding or when specifically required in the following section.

Re-entrant corners shall be free from notches and shall have largest practical radii with a minimum radius of 15 mm.

24.2.3.1 *Shearing*

Shearing of items over 16 mm thick to be galvanized and subject to tensile force or bending moment shall not be carried out, unless the item is stress relieved subsequently.

The use of sheared edges in the tension area shall be avoided in location subject to plastic hinge rotation at factored loading.

24.2.3.2 *Thermal cutting*

Gas cutting of high tensile steel by mechanically controlled torch may be permitted, provided special care is taken to leave sufficient metal to be removed by machining, so that all metal that has been hardened by flame is removed. Hand flame cutting may be permitted only subject to the approval of the inspecting authority.

Except where the material is subsequently joined by welding, no load shall be transmitted through a gas cut surface.

Thermally cut free edges, which shall be subject to calculated static tensile stress shall be free from round bottom gouges greater than 5 mm deep. Gouges greater than 5 mm deep and notches shall be removed by grinding.

24.2.4 *Holing*

24.2.4.1 Holes through more than one thickness of material for members, such as compound stanchion and girder flanges, shall be where possible, drilled after the members are assembled and tightly clamped or bolted together. A round hole for a bolt shall either be machine flame cut, or drilled full size, or sub-punched 3 mm undersize and reamed to size or punched full size.

Hand flame cutting of a bolt hole shall not be permitted except as a site rectification measure for holes in column base plates.

24.2.4.2 *Punching*

A punched hole shall be permitted only in material whose yield stress (f_y) does not exceed 360 MPa and where thickness does not exceed ($5600/f_y$) mm. In cyclically loaded details, punching shall be avoided in plates with thickness greater than 12 mm.

For greater thickness and cyclically loaded details, holes shall be either drilled from the solid or sub-punched or sub drilled and reamed.

The die for all sub-punched holes or the drill for all sub-drilled holes shall be at least 3 mm smaller than the required diameter of finished hole.

24.2.4.3 *Oversize holes*

A special plate washer of minimum thickness 4 mm shall be used under the nut, if the hole diameter is larger than the bolt diameter by 3 mm or more.

Oversize hole shall not exceed $1.25d$ or ($d + 8$) mm in diameter, were d is the nominal bolt diameter, in mm.

A short slotted hole shall not exceed the appropriate hole size in width and $1.33d$, in length. A long slotted hole shall not exceed the appropriate hole size in width and $2.5d$, in length. If the slot length is larger than those specified, shear transfer in the direction of slot is not admissible even in friction type of connection.

Slotted holes shall be punched either in one operation or else formed by punching or drilling two round holes apart and completed by high quality mechanically controlled flame cutting and dressing to ensure that bolt can freely travel the full length of the slot.

24.2.4.4 *Fitted bolt holes*

Holes for turned and fitted bolts shall be drilled to a diameter equal to the nominal diameter of the shank or barrel subject to tolerance specified in the accepted standards [C-6A(47)]. Preferably, parts to be connected with close tolerance or barrel bolts shall be firmly held together by tacking bolts or clamps and the holes drilled through all the thicknesses at one operation and subsequently reamed to size. All holes not drilled through all thicknesses at one operation shall be drilled to a smaller size and reamed out after assembly. Where this is not practicable, the parts shall be drilled and reamed separately through hard bushed steel jigs.

24.2.4.5 Holes for rivets or bolts shall not be formed generally by gas cutting process. However, advanced gas cutting processes such as plasma cutting may be used to make holes in statically loaded members only. In cyclically loaded members subjected to tensile stresses which are vulnerable under fatigue, gas cutting shall not be used unless subsequent reaming is done to remove the material in the heat affected zone around the hole.

24.3 Assembly

All parts of bolted members shall be pinned or bolted and rigidly held together during assembly.

The component parts shall be assembled and aligned in such a manner that they are neither twisted nor otherwise damaged, and shall be so prepared that the specified camber, if any, is provided.

24.3.1 *Holes in Assembly*

When holes are drilled in one operation through two or more separable parts, these parts, when so specified by the engineer, shall be separated after drilling and the burrs removed.

Matching holes for rivets and black bolts shall register with each other so that a gauge of 1.5 mm or 2.0 mm (as the case may be, depending on whether the diameter of the rivet or bolt is less than or more than 25 mm) less in diameter than the diameter of the hole will pass freely through the assembled members in the direction at right angle to such members.

Drilling done during assembly to align holes shall not distort the metal or enlarge the holes.

Holes in adjacent part shall match sufficiently well to permit easy entry of bolts. If necessary, holes except oversize or slotted holes may be enlarged to admit bolts, by moderate amount of reaming.

24.3.2 *Thread Length*

When design is based on bolts with unthreaded shanks in the shear plane, appropriate measures shall be specified to ensure that, after allowing for tolerance, neither the threads nor the thread run-out be in the shear plane.

The length of bolt shall be such that at least one clear thread shows above the nut and at least one thread plus the thread run out is clear beneath the nut after tightening. One washer shall be provided under the rotated part.

24.3.3 *Assembly Subjected to Vibration*

When non-preloaded bolts are used in a structure subject to vibration, the nuts shall be secured by locking devices or other mechanical means. The nuts of preloaded bolts may be assumed to be sufficiently secured by the normal tightening procedure.

24.3.4 *Washers*

Washers are not normally required on non-preloaded bolts, unless specified otherwise. Tapered washers shall be used where the surface is inclined at more than 3° to a plane perpendicular to the bolt axis.

Hardened washer shall be used for preloaded bolts or the nut, whichever is to be rotated.

All material within the grip of the bolt shall be steel and no compressible material shall be permitted in the grip.

24.4 Riveting

24.4.1 Rivets shall be heated uniformly throughout their length, without burning or excessive scaling, and shall be of sufficient length to provide a head of standard dimensions. These shall, when driven, completely fill the holes and, if countersunk, the countersinking shall be fully filled by the rivet. If required, any protrusion of the countersunk head shall be dressed off flush.

24.4.2 Riveted member shall have all parts firmly drawn and held together before and during riveting, and special care shall be taken in this respect for all single-riveted connections. For multiple riveted connections, a service bolt shall be provided in every third or fourth hole.

24.4.3 Wherever practicable, machine riveting shall be carried out by using machines of the steady pressure type.

24.4.4 All loose, burned or otherwise defective rivets shall be cut out and replaced before the structure is loaded, and special care shall be taken to inspect all single riveted connections.

24.4.5 Special care shall be taken in heating and driving long rivets.

24.5 Bolting

24.5.1 In all cases where the full bearing area of the bolt is to be developed, the bolt shall be provided with a washer of sufficient thickness under the nut to avoid any threaded portion of the bolt being within the thickness or the parts bolted together, unless accounted for in design.

24.5.2 Pre-tensioned bolts shall be subjected to initial tension (the proof stress) by an appropriate pre-calibrated method.

24.6 Welding

24.6.1 Welding shall be in accordance with good practices [C-6A(48)], as appropriate.

24.6.2 For welding of any particular type of joint, welders shall give evidence acceptable to the purchaser of having satisfactorily completed appropriate tests as prescribed in good practices [C-6A(49)], as relevant.

24.6.3 Assembly and welding shall be carried out in such a way to minimize distortion and residual stress and that the final dimensions are within appropriate tolerances.

24.7 Machining of Butts, Caps and Bases

24.7.1 Column splices and butt joints of struts and compression members, depending on contact for stress transmission, shall be accurately machined and close-butted over the whole section with a clearance not exceeding 0.2 mm locally, at any place. Sum of all such clearance shall not be more than 30 percent of the contact area for stress transmission. In column caps and bases, the ends of shafts together with the attached gussets, angles, channels, etc; after connecting together should be accurately machined so that clearance between the contact surfaces shall not exceed 2 mm locally, subject further to the condition that sum total of all such clearance shall not exceed 30 percent of the total contact area for stress transmission. Care should be taken that these gussets, connecting angles or channels are fixed with such accuracy that they are not reduced in thickness by machining by more than 2.0 mm.

24.7.2 Where sufficient gussets and rivets or welds are provided to transmit the entire loading (*see* provisions under **11**), the column ends need not be machined.

24.7.3 *Slab Bases and Caps*

Slab bases and slab caps, except when cut from material with true surfaces, shall be accurately machined over the bearing surfaces and shall be in effective contact with the end of the stanchion, the bearing face which is to be grouted to fit tightly at both top and bottom, unless welds are provided to transmit the entire column face.

24.7.4 To facilitate grouting, sufficient gap shall be left between the base plates and top of pedestal and holes shall be provided where necessary in stanchion bases for the escape of air.

24.8 Painting

24.8.1 Painting shall be done in accordance with the good practice good practices [C-6A(50)].

22.8.2 All surfaces, which are to be painted, oiled or otherwise treated, shall be dry and thoroughly cleaned to remove all loose scale and loose rust.

24.8.3 Shop contact surfaces need not be painted unless specified. If so specified, they shall be brought together while the paint is still wet.

24.8.4 Surfaces not in contact, but inaccessible after shop assembly, shall receive the full specified protective treatment before assembly. This does not apply to the interior of sealed hollow sections.

24.8.5 Chequered plates shall be painted but the details of painting shall be specified by the purchaser.

24.8.6 In case of surfaces to be welded, the steel shall not be painted or metal coated within a suitable distance of any edge to be welded, if the paint specified or the metal coating is likely to be harmful to welders or impair the quality of the welds.

24.8.7 Welds and adjacent parent metal shall not be painted prior to de-slagging, inspection and approval.

24.8.8 Parts to be encased in concrete shall not be painted or oiled.

24.8.9 Contact surface in friction type connection shall not be painted in advance.

24.9 Marking

Each piece of steel work shall be distinctly marked before dispatch, in accordance with a marking diagram and shall bear such other marks as will facilitate erection.

24.10 Shop Erection

24.10.1 The steel work shall be temporarily shop erected complete or as arranged with the inspection agency so that accuracy of fit may be checked before dispatch. The parts shall be shop assembled with sufficient numbers of parallel drifts to bring and keep the parts in place.

24.10.2 In the case of parts drilled or punched, through steel jigs with bushes resulting in all similar parts being interchangeable, the steelwork may be shop erected in such position as arranged with the inspection agency.

24.10.3 In case of shop fabrication using numerically controlled machine data generated by computer software (like CAD), the shop erection may be dispensed with at the discretion of the inspector.

24.11 Packing

All projecting plates or bars and all ends of members at joints shall be stiffened, all straight bars and plates shall be bundled, all screwed ends and machined surfaces shall be suitably packed and all rivets, bolts, nuts, washers and small and loose parts shall be packed separately in cases, so as to prevent damage or distortion during transit.

24.12 Inspection and Testing

24.12.1 The inspecting authority shall have free access at all reasonable times to those parts of the manufacturer’s works which are concerned with the fabrication of the steelwork and shall be afforded all reasonable facilities for satisfying himself that the fabrication is being undertaken in accordance with the provisions of this section.

24.12.2 Unless specified otherwise, inspection shall be made at the place of manufacture prior to dispatch and shall be conducted so as not to interfere unnecessarily with the operation of the work.

24.12.3 The manufacturer shall guarantee compliance with the provisions of this standard, if required to do so by the purchaser.

24.12.4 Should any structure or part of a structure be found not to comply with any of the provisions of this section, it shall be liable to rejection. No structure or part of the structure, once rejected shall be resubmitted for test, except in cases where the purchaser or his authorized representative considers the defect as rectifiable.

24.12.5 Defects, which may appear during fabrication, shall be made good with the consent of and according to the procedure laid down by the inspecting authority.

24.12.6 All gauges and templates necessary to satisfy the inspection authority shall be supplied by the manufacturer. The inspecting authority may, at his discretion, check the test results obtained at the manufacturer’s works by independent testing at outside laboratory, and should the material so tested be found to be unsatisfactory, the cost of such tests shall be borne by the manufacturer, and if found satisfactory, the cost shall be borne by the purchaser.

24.13 Site Erection

24.13.1 *Plant and Equipment*

The suitability and capacity of all plant and equipment used for erection shall be to the satisfaction of the engineer.

24.13.2 *Storing and Handling*

All structural steel should be so stored and handled at the site that the members are not subjected to excessive stresses and damage by corrosion due to exposure to environment.

24.13.3 *Setting Out*

The positioning and leveling of all steelwork, the plumbing of stanchions and the placing of every part of the structure with accuracy shall be in accordance with the approved drawings and to the satisfaction of the engineer in accordance with the deviation permitted below.

24.13.3.1 *Erection tolerances*

Unloaded steel structure, as erected, shall satisfy the tolerance criteria specified in the accepted standards [C-6A(47)].

24.13.4 *Safety during Fabrication and Erection*

24.13.4.1 All steel materials including fabricated structures, either at fabrication shop or at erection site, shall be handled only by a worker skilled in such jobs; where necessary with load tested lifting devices, having tested wire rope slings of correct size. The devices should be well maintained and operated by experienced operators.

24.13.4.2 Oxygen and acetylene cylinders and their hoses shall have distinctive colours. Cylinders should be stored in upright position in well-ventilated rooms or in open air, not exposed to flames, naked lights or extreme heat and should also be in upright position when they are being used. All gas cutting works shall be done only by experienced skilled gas cutters, equipped with gloves, boots, aprons, goggles and good cutting sets of approved make.

24.13.4.3 While doing any welding work, it should be ensured that the welding machine is earthed and the welding cables are free from damage. The welder and his assistant shall use a face shield or head shield with a welding lens and clear cover glass and their hands, legs and bodies shall be well protected by leather gloves, shoes and aprons. Combustible materials should be kept away from the sparks and globules of molten metals generated in any arc welding. In case of welding in a confined place, it should be provided with an exhaust system to take care of the harmful gases, fumes and dusts generated.

24.13.4.4 In addition to precautions against all the hazards mentioned above, erection workers shall also be protected in the following manner:

a) all workers shall wear helmets and shall also be provided with gloves and shoes. In addition those working at heights shall use safety belts;

b) all structures shall be so braced/guyed during erection that there is no possibility of collapse before erection work is completed; and

c) warning signs such as 'DANGER', 'CAUTION', '440 V', 'DO NOT SMOKE', 'LOOK AHEAD', etc; should be displayed at appropriate places.

24.13.4.5 For detailed safety precautions during erection, reference shall be made to the good practice [C-6A(51)].

24.13.5 *Field Connections*

24.13.5.1 *Field riveting*

Rivets driven at the site shall be heated and driven with the same care as those driven in the shop.

24.13.5.2 *Field bolting*

Field bolting shall be carried out with the same care as required for shop bolting.

24.13.5.3 *Fillet welding*

Field assembly and welding shall be executed in accordance with the requirements for shop fabrications excepting such as manifestly apply to shop conditions only. Where the steel has been delivered painted, the paint shall be removed for a distance of at least 50 mm on either side of the joint.

24.14 Painting after Erection

24.14.1 Before painting of such steel which is delivered unpainted is commenced, all surfaces to be painted shall be dry and thoroughly cleaned from all loose scale and rust, as required by the surface protection specification.

24.14.2 The specified protective treatment shall be completed after erection. All rivet and bolt heads and the site welds after de-slagging shall be cleaned. Damaged or deteriorated paint surfaces shall first be made good with the same type of paint as the shop coat. Where specified, surfaces which will be in contact after site assembly, shall receive a coat of paint (in addition to any shop priming) and shall be brought together while the paint is still wet. No painting shall be used on contact surfaces in the friction connection, unless specified otherwise by the design document.

24.14.3 Where the steel has received a metal coating in the shop, this coating shall be completed on site so as to be continuous over any welds and site rivets or bolts, subject to the approval of the engineer. Painting on site may complete protection. Bolts, which have been galvanized or similarly treated, are exempted from this requirement.

24.14.4 Surface, which will be inaccessible after site assembly, shall receive the full-specified protective treatment before assembly.

24.14.5 Site painting should not be done in frosty or foggy weather, or when humidity is such as to cause condensation on the surfaces to be painted.

24.15 Bedding Requirement

24.15.1 Bedding shall be carried out with Portland cement grout or mortar, as described under **24.15.4** or fine cement concrete in accordance with good practice [C-6A(52)].

24.15.2 For multistoried buildings, this operation shall not be carried out until a sufficient number of bottom lengths of stanchions have been properly lined, levelled and plumbed and sufficient floor beams are in position.

24.15.3 Whatever method is employed, the operation shall not be carried out until the steelwork has been finally levelled and plumbed, stanchion bases being supported meanwhile by steel wedges or nuts; and immediately before grouting, the space under the steel shall be thoroughly cleaned.

24.15.4 Bedding of structure shall be carried out with grout or mortar, which shall be of adequate strength and shall completely fill the space to be grouted and shall either be placed under pressure or by ramming against fixed supports. The grouts or mortar used shall be non-shrinking variety.

24.16 Steelwork Tenders and Contracts

A few recommendations are given in Annex H for general information.

ANNEX A

(*Clause* 4)

SYMBOLS

Symbols used in this section shall have the following meanings with respect to the structure or member or condition, unless otherwise defined elsewhere in this Section:

A = area of cross section;

A_c = area at root of threads;

A_e = effective cross sectional area;

A_{ef} = reduced effective flange area;

A_f = total flange area;

A_g = gross cross sectional area;

A_{gf} = gross cross sectional area of flange;

A_{go} = gross cross sectional area of outstanding (not connected) leg of a member;

A_n = net area of the total cross section;

A_{nb} = net tensile cross sectional area of bolt;

A_{nc} = net cross sectional area of the connected leg of a member;

A_{nf} = net cross sectional area of each flange;

A_{no} = net cross sectional area of outstanding (not connected) leg of a member;

A_{pb} = nominal bearing area of bolt on any plate;

A_q = cross sectional area of a bearing (load carrying) stiffener in contact with the flange;

A_s = tensile stress area;

A_{sb} = gross cross sectional area of a bolt at the shank;

A_{tg} = gross sectional area in tension from the centre of the hole to the toe of the angle section/channel section, etc (block shear failure, *see* **13.4**) perpendicular to the line of force;

A_{tn} = net sectional area in tension from the centre of the hole to the toe of the angle perpendicular to the line of force block shear failure (*see* **13.4**);

A_v = shear area;

A_{vg} = gross cross sectional area in shear along the line of transmitted force (*see* **13.4**);

A_{vn} = net cross sectional area in shear along the line of transmitted force (*see* **13.4**);

a, b = larger and smaller projection of the slab base beyond the rectangle circumscribing the column, respectively (*see* **14.4**);

a_o = peak acceleration;

a_1 = unsupported length of individual elements being laced between lacing points;

B = length of side of cap or base plate of a column;

b = outstand/width of the element;

b_1 = stiff bearing length;

b_e = effective width of flange between pair of bolts;

b_f = width of the flange;

b_i = width of flange as an internal element;

b_o = width of flange outstand;

b_p = panel zone width between column flanges at beam-column junction;

b_s = shear lag distance;

b_t = width of tension field;

b_w = width of outstanding leg;

C = centre to centre longitudinal distance of battens;

C_m = coefficient of thermal expansion;

c = spacing of transverse stiffener;

c_b = moment amplification factor for braced member;

c_m = moment reduction factor for lateral torsional buckling strength calculation;

c_s = moment amplification factor for sway frame;

D = overall depth/diameter of the cross section;

d = depth of web, Nominal diameter;

d_2 = twice the clear distance from the compression flange angles, plates or tongue plates to the neutral axis;

d_h = diameter of a bolt/rivet hole;

d_o = nominal diameter of the pipe column or the dimensions of the column in the depth direction of the base plate;

d_p = panel zone depth in the beam-column junction;

E = modulus of elasticity for steel;

$E\ (T)$ = modulus of elasticity of steel at T ºC;

E (20) = modulus of elasticity of steel at 20 ºC;

E_p = modulus of elasticity of the panel material;

F_{cdw} = buckling strength of un-stiffened beam web under concentrated load;

F_d = factored design load;

F_n = normal force;

F_o = minimum proof pretension in high strength friction grip bolts;

F_{psd} = bearing capacity of load carrying stiffener;

F_q = stiffener force;

F_{qd} = stiffener buckling resistance;

F_{test} = test load;

$F_{test,a}$ = load for acceptance test;

$F_{test,\ Min}$ = minimum test load from the test to failure;

$F_{test,\ R}$ = test load resistance;

$F_{test,\ S}$ = strength test load;

F_w = design capacity of the web in bearing;

F_x = external load, force or reaction;

F_{xd} = buckling resistance of load carrying web stiffener;

f = actual normal stress range for the detail category;

f_1 = frequency for a simply supported one way system;`

f_2 = frequency of floor supported on steel girder perpendicular to the joist;

f_a = calculated stress due to axial force at service load;

f_{abc} = permissible bending stress in compression at service load;

f_{ac} = permissible compressive stress at service load;

f_{abt} = permissible bending stress in tension at service load;

f_{apb} = permissible bearing stress of the bolt at service load;

f_{asb} = permissible stress of the bolt in shear at service load;

f_{at} = permissible tensile stress at service load;

f_{atb} = permissible tensile stress of the bolt at service load;

f_{aw} = permissible stress of the weld at service load;

f_b = actual bending stress at service load;

f_{bc} = actual bending stress in compression at service load;

f_{bd} = design bending compressive stress corresponding to lateral buckling;

f_{br} = actual bearing stress due to bending at service load;

f_{bt} = actual bending stress in tension at service load;

f_{bs} = permissible bending stress in column base at service load;

f_c = actual axial compressive stress at service load;

f_{cr} = elastic buckling stress of a column, Euler buckling stress;

f_{cd} = design compressive stress;

$f_{cr,b}$ = extreme fibre compressive stress corresponding to elastic lateral buckling moment;

f_e = equivalent stress at service load;

f_f = fatigue stress range corresponding to 5×10^6 cycles of loading;

f_{feq} = equivalent constant amplitude stress;

f_{fd} = design normal fatigue strength;

$f_{f,\ Max}$ = highest normal stress range;

f_{fn} = normal fatigue stress range;

f_{nw} = normal stress in weld at service load;

f_o = proof stress;

f_p = actual bearing stress at service load;

f_{pb} = actual bearing stress in bending at service load;

f_{psd} = bearing strength of the stiffeners;

f_r = frequency;

f_{sb} = actual shear stress in bolt at service load;

f_t = actual tensile stress at service load;

f_{tb} = actual tensile stress of the bolt at service load;

f_u = characteristic ultimate tensile stress;

f_{ub} = characteristic ultimate tensile stress of the bolt;

f_{um} = average ultimate stress of the material as obtained from test;

f_{up} = characteristic ultimate tensile stress of the connected plate;

f_v = applied shear stress in the panel designed utilizing tension field action;

f_w = actual stress of weld at service load;

f_{wd} = design stress of weld at service load;

f_{wn} = nominal strength of fillet weld;

f_x = maximum longitudinal stress under combined axial force and bending;

f_y = characteristic yield stress;

$f_y(T)$ = yield stress of steel at T °C;

$f_y(20)$ = yield stress of steel at 20 °C ;

f_{yb} = characteristic yield stress of bolt;

f_{yf} = characteristic yield stress of flange;

f_{ym} = average yield stress as obtained from test;

f_{yp} = characteristic yield stress of connected plate;

f_{yq} = characteristic yield stress of stiffener material;

f_{yw} = characteristic yield stress of the web material;

G = modulus of rigidity for steel;

g = gauge length between centres of the holes perpendicular to the load direction, acceleration due to gravity;

h = depth of the section;

h_b = total height from the base to the floor level concerned;

h_c = height of the column;

h_e = effective thickness;

h_f = centre to centre distance of flanges;

h_i = thickness of fire protection material;

h_L = height of the lip;

h_s = storey height;

h_y = distance between shear centre of the two flanges of a cross section;

I = moment of inertia of the member about an axis perpendicular to the plane of the frame;

I_{fc} = moment of inertia of the compression flange of the beam about the axis parallel to the web;

I_f = moment of inertia of the tension flange of the beam about minor axis;

I_q = moment of inertia of a pair of stiffener about the centre of the web, or a single stiffener about the face of the web;

I_s = second moment of inertia;

I_{so} = second moment of inertia of the stiffener about the face of the element perpendicular to the web;

I_T = transformed moment of inertia of the one way system (in terms of equivalent steel, assuming the concrete flange of width equal to the spacing of the beam to be effective);

I_t = St. Venant’s torsion constant;

I_w = warping constant;

I_y = moment of inertia about the minor axis of the cross section;

I_z = moment of inertia about the major axis of the cross section;

K_b = effective stiffness of the beam and column;

K_h = reduction factor to account for the high strength friction grip connection bolts in oversized and slotted holes Effective length of the member;

KL = appropriate effective slenderness ratio of the section;

KL/r = effective slenderness ratio of the section about the minor axis of the section;

KL/r = effective slenderness ratio of the section about the major axis of the section;

$\left(\frac{KL}{r}\right)_o$ = actual maximum effective slenderness ratio of the laced column;;

$\left(\frac{KL}{r}\right)_e$ = effective slenderness ratio of the laced column accounting for shear deformation;

K_v = shear buckling co-efficient;

K_w = warping restraint factor;

k = regression coefficient;

k_{sm} = exposed surface area to mass ratio;

K_y, K_z, K_{LT} = moment amplification factors;

L = actual length, unsupported length, length centre to centre distance of the intersecting members, cantilever length;

L_c = length of end connection in bolted and welded members, taken as the distance between outermost fasteners in the end connection, or the length of the end weld, measured along the length of the member;

L_{LT} = effective length for lateral torsional buckling;

L_m = maximum distance from the restraint to the compression flange at the plastic hinge to an adjacent restraint (limiting distance);

L_o = length between points of zero moment (inflection) in the span;

l = centre to centre length of the supporting member;

l_e = distance between prying force and bolt centre line;

l_g = grip length of bolts in a connection;

l_j = length of the joint;

l_s = length between points of lateral support to the compression flange in a beam;

l_v = distance from bolt centre line to the toe of fillet weld or to half the root radius for a rolled section;

l_w = length of weld;

M = bending moment;

M_a = applied bending moment;

M_{cr} = elastic critical moment corresponding to lateral torsional buckling of the beam;

M_d = design flexural strength;

M_{dv} = moment capacity of the section under high shear;

M_{dy} = design bending strength about the minor axis of the cross section;

M_{dz} = design bending strength about the major axis of the cross section;

M_{eff} = reduced effective moment;

M_{fr} = reduced plastic moment capacity of the flange plate;

M_{fd} = design plastic resistance of the flange alone;

M_{nd} = design bending strength under combined axial force and uniaxial moment;

M_{ndy}, M_{ndz} = design bending strength under combined axial force and the respective uniaxial moment acting alone;

M_p = plastic moment capacity of the section;

M_{pb} = moment in the beam at the intersection of the beam and column centre lines;

M_{pc} = moments in the column above and below the beam surfaces;

M_{pd} = plastic design strength;

M_{pdf} = plastic design strength of flanges only;

M_q = applied moment on the stiffener;

M_s = Moment at service (working) load

M_{tf} = moment resistance of tension flange;

M_y = factored applied moment about the minor axis of the cross section;

M_{yq} = moment capacity of the stiffener based on its elastic modulus;

M_z = factored applied moment about the major axis of the cross section;

N = number of parallel planes of battens;

N_d = design strength in tension or in compression;

N_f = axial force in the flange;

N_{SC} = number of stress cycles;

n = number of bolts in the bolt group/critical section;

n_e = number of effective interfaces offering frictional resistance to slip;

n_n = number of shear planes with the threads intercepting the shear plane in the bolted connection;

n_s = number of shear planes without threads intercepting the shear plane in the bolted connection;

P = factored applied axial force;

P_{cr} = elastic buckling load

P_d = design axial compressive strength;

P_{dy}, P_{dz} = design compression strength as governed by flexural buckling about the respective axis;

P_e = elastic Euler buckling load;

P_{min} = minimum required strength for each flange splice;

P_r = required compressive strength;

P_s = actual compression at service load;

P_y = yield strength of the cross section under axial compression;

p = pitch length between centres of holes parallel to the direction of the load;

p_s = staggered pitch length along the direction of the load between lines of the bolt holes (*see* Fig. 5);

Q = prying force;

Q_a = accidental load (Action);

Q_c = characteristic loads (Action);

Q_d = design load (Action);

Q_p = permanent loads (Action);

Q_v = variable loads (Action);

q = shear stress at service load;

R = ratio of the mean compressive stress in the web (equal to stress at mid depth) to yield stress of the web; reaction of the beam at support ;

R_d = design strength of the member at room temperature ;

R_i = net shear in bolt group at bolt 'i';

R_r = response reduction factor;

R_{tf} = flange shear resistance;

R = ultimate strength of the member at room temperature;

u = appropriate radius of gyration;

r = minimum radius of gyration of the individual element being laced together;

r_1 = ratio of the design action on the member under fire to the design capacity;

r_f = radius of gyration about the minor axis (v-v) of angle section;

r_{vv} = radius of gyration about the minor axis;

r_y = radius of gyration about the major axis;

r_z = minimum transverse distance between the centroid of the rivet or bolt group or weld group;

S = constant stress range;

S_c = design strength;

S_d = original cross sectional area of the test specimen;

S_o = spring stiffness;

S_p = ultimate strength;

S_u = anchorage length of tension field along the compression flange;

s_c = anchorage length of tension field along the tension flange;

s_t = actual stiffener spacing;

s_a = ratio of the mean compressive stress in the web (equal to stress at mid depth) to yield stress of the web; reaction of the beam at support;

T = temperature in degree Celsius; Factored tension;

T_b = applied tension in bolt;

T_{cf} = thickness of compression flange;

T_d = design strength under axial tension;

T_{dg} = yielding strength of gross section under axial tension;

T_{dn} = rupture strength of net section under axial tension;

T_{db} = design strength of bolt under axial tension, Block shear strength at end connection;

T_e = externally applied tension;

T_f = factored tension force of friction type bolt;

T_l = limiting temperature of the steel;

T_{nb} = nominal strength of bolt under axial tension;

T_{nd} = design tension capacity;

T_{ndf} = design tension capacity of friction type bolt;

T_{nf} = nominal tensile strength of friction type bolt;

T_s = actual tension under service load;

t = thickness of element/angle, time in minutes;

t_f = thickness of flange;

t_p = thickness of plate;

t_{pk} = thickness of packing;

t_q = thickness of stiffener;

t_s = thickness of base slab;

t_t = effective throat thickness of welds;

t_w = thickness of web;

V = factored applied shear force;

V_b = shear in batten plate;

V_{bf} = factored frictional shear force in friction type connection;

V_{cr} = critical shear strength corresponding to web buckling;

V_d = design shear strength;

V_{db} = block shear strength;

V_n = nominal shear strength of bolt;

V_{nbf} = bearing capacity of bolt for friction type connection;

V_p = plastic shear resistance under pure shear;

V_n = nominal shear strength;

V_{npb} = nominal bearing strength of bolt;

V_{nsb} = nominal shear capacity of a bolt;

V_{nsf} = nominal shear capacity of bolt as governed by slip in friction type connection;

V_s = transverse shear at service load;

V_{sb} = factored shear force in the bolt;

V_{sd} = design shear capacity;

V_{sdf} = design shear strength in friction type bolt;

V_{sf} = factored design shear force of friction bolts;

V_t = applied transverse shear;

V_{tf} = shear resistance in tension field;

W = total load;

w = uniform pressure from below on the slab base due to axial compression under the factored load;

w_{tf} = width of tension field;

x_t = torsional index;

Z_e = elastic section modulus;

Z_{ec} = elastic section modulus of the member with respect to extreme compression fibre;

Z_{et} = elastic section modulus of the member with respect to extreme tension fibre;

Z_p = plastic section modulus;

Z_v = contribution to the plastic section modulus of the total shear area of the cross section;

y_g = distance between point of application of the load and shear centre of the cross section;

y_s = co-ordinate of the shear centre in respect to centroid;

α = imperfection factor for buckling strength in columns and beams;

α_t = coefficient of thermal expansion;

β_M = ratio of smaller to the larger bending moment at the ends of a beam column;

β_{My}, β_{Mz} = equivalent uniform moment factor for flexural buckling for y-y and axes, respectively;

β_{MLT} = equivalent uniform moment factor for lateral torsional buckling;

χ = strength reduction factor to account for buckling under compression;

χ_m = strength reduction factor, χ, at f_{ym};

χ_{LT} = strength reduction factor to account for lateral torsional buckling of beams;

δ = storey deflection;

δ_L = horizontal deflection of the bottom of storey due to combined gravity and notional load;

δ_p = load amplification factor;

δ_u = horizontal deflection of the top of storey due to combined gravity and notional load;

ϕ = inclination of the tension field stress in web;

γ = unit weight of steel;

γ_L = partial safety factor for load;

γ_m = partial safety factor for material;

γ_{m0} = partial safety factor against yield stress and buckling;

γ_{m1} = partial safety factor against ultimate stress;

γ_{mb} = Partial safety factor for bolted connection with bearing type bolts;

γ_{mf} = partial safety factor for bolted connection with high strength friction grip bolts;

γ_{fft} = partial safety factor for fatigue load;

γ_{mft} = partial safety factor for fatigue strength;

γ_{mv} = partial safety factor against shear failure;

γ_{mw} = partial safety factor for strength of weld;

ε = yield stress ratio, $(250 / f_y)^{1/2}$;

λ = Non dimensional slenderness ratio $= \sqrt{f_y (KL/r)^2 / \pi^2 E} = \sqrt{f_y / f_{cr}} = \sqrt{P_y / P_{cr}}$

λ_{cr} = elastic buckling load factor;

λ_e = equivalent slenderness ratio;

λ_{LT} = non-dimensional slenderness ratio in lateral bending;

λ_{scr} = elastic buckling load factor of each storey;

μ = poisson's ratio;

μ_c = correction factor;

μ_f = coefficient of friction (slip factor);

μ_r = capacity reduction factor;

θ = ratio of the rotation at the hinge point to the relative elastic rotation of the far end of the beam segment containing plastic hinge;

ρ = unit mass of steel;

τ = actual shear stress range for the detail category;

τ_{b} = buckling shear stress;

τ_{ab} = permissible shear stress at the service load;

$\tau_{cr,e}$ = elastic critical shear stress;;

τ_{f} = fatigue shear stress range;

$\tau_{f, Max}$ = highest shear stress range;

τ_{fd} = design shear fatigue strength;

τ_{fn} = fatigue shear stress range at N_{SC} cycle for the detail category;

τ_{v} = actual shear stress at service load;

ψ = ratio of the moments at the ends of the laterally unsupported length of a beam; and

Γ = frame buckling load factor.

NOTE — The subscripts y, z denote the y-y and z-z axes of the section, respectively. For symmetrical sections, y-y denotes the minor principal axis whilst z-z denotes the major principal axis (*see* **8**).

ANNEX B

[*Clauses* 11.1.1(c) *and* 11.7.2.1(b)]

ANALYSIS AND DESIGN METHODS

B-1 ADVANCED STRUCTURAL ANALYSIS AND DESIGN

B-1.1 Analysis

For a frame, comprising members of compact section with full lateral restraint, an advanced structural analysis may be carried out, provided the analysis can be shown to accurately model the actual behaviour of that class of frames. The analysis shall take into account the relevant material properties, residual stresses, geometrical imperfections, reduction in stiffness due to axial compression, second-order effects, section strength and ductility, erection procedures and interaction with the foundations.

Advanced structural analysis for earthquake loads shall take into account provisions of **5** of Part C 'Strucutral design/Section 1 Loads and Load Effects' of this NBCS.

B-1.2 Design

For the strength limit state, it shall be sufficient to satisfy the section capacity requirements given under **15** for the members subjected to bending, under **14** for axial members, under **16** for combined forces and under **17** for connections. Effect of moment magnification given in **16**, instability given in **14** and lateral buckling given in **15** need not be considered while designing the member, since advanced analysis methods directly consider these.

B-2 SECOND ORDER ELASTIC ANALYSIS AND DESIGN

B-2.1 Analysis

In a second-order elastic analysis, the members shall be assumed to remain elastic, and changes in frame geometry under the design load and changes in the effective stiffness of the members due to axial forces shall be accounted for. In a frame where the elastic buckling load factor (λ_{cr}) of the frame as determined in accordance with **11.6** is greater than 5, the changes in the effective stiffness of the members due to axial forces may be neglected.

B-2.2 Design Bending Moment

The design bending moment under factored load shall be taken as the maximum bending moment in the length of the member. It shall be determined either:

a) directly from the second-order analysis; or

b) approximately, if the member is divided into a sufficient number of elements, as the greatest of the element end bending moments, or;

c) by amplifying the calculated design bending moment, taken as the maximum bending moment along the length of a member as obtained by superposition of the simple beam bending moments determined by the analysis.

For a member with zero axial force or a member subject to axial tension, the factored design bending moment shall be calculated as the moment obtained from second-order analysis without any amplification.

For a member with a design axial compressive force as determined from the analysis, the factored design bending moment shall be calculated as follows:

$$M = \delta_b M_m$$

where

δ_b = moment amplification factor for a braced member determined in accordance with **16**.

B-3 FRAME INSTABILITY ANALYSIS

B-3.1 Analysis

Frame instability, as treated here, is related to the design of multi-storey rigid-jointed frames subject to side sway. The elastic critical load factor, λ_{cr} may be determined using the deflection method as given in **B-3.2** or any other recognized method. This is used to calculate the amplified sway moments for elastic designs and to check frame stability in plastic designs. The elastic critical load factor, λ_{cr} of a frame is the ratio by which each of the factored loads would have to be increased to cause elastic instability.

B-3.2 Deflection Method

An accurate method of analysis (ordinary linear elastic analysis) should be used to determine the horizontal deflections of the frame due to horizontal forces applied at each floor level, which is equal to the notional horizontal load in **11.3.6**. Allowance should be made for the degree of rigidity of the base as given in **B-3.2** in this deflection calculation.

The base stiffness should be determined by reference to **11.3.4**.
The elastic critical load factor, λ_{cr} is calculated as:

$$\lambda_{cr} = \frac{1}{200\phi_{s,Max}}$$

where
$\phi_{s,Max}$ = largest value of the sway index where, ϕ_s given by:

$$\phi_{si} = \frac{\delta_{ui} - \delta_{Li}}{h_i}$$

where

h_i = storey height;

δ_{ui} = horizontal deflection of the top of the storey due to the combined gravity and notional loads; and

δ_{Li} = horizontal deflection of the bottom of the storey due to gravity and notional load.

B-3.3 Partial Sway Bracing

In any storey the stiffening effect of infill wall panels may be allowed for by introducing a diagonal strut in that storey of area *A*, given by:

$$A = \frac{k_3 \sum K_c}{h(h/b)} \left[1 + (h/b)^2\right]^{3/2}$$

where

h = storey height;

b = width of the braced bay;

$\sum K_c$ = sum of the stiffness *I/L*, of the columns in that storey;

$k_3 = \frac{h^2 \sum S_p}{80E \sum K_C} \le 2$; and

$\sum S_p$ = Sum of spring stiffness (horizontal force per unit horizontal deflection of all the panels in that storey determined from:

$$S_p = \frac{0.6h/b}{\left[1 + (h/b)^2\right]^2} \, t_p E_p$$

where

t_p = thickness of the wall panel; and

E_p = modulus of elasticity of the panel material.

ANNEX C

[*Clauses* 12.2.2.2 *and* 12.6.2]

DESIGN AGAINST FLOOR VIBRATION

C-1 GENERAL

Floor with longer spans of lighter construction and less inherent damping are vulnerable to vibrations under normal human activity. Natural frequency of the floor system corresponding to the lowest mode of vibration, damping characteristics, are important characteristics in floor vibration. Open web steel joists (trusses) or steel beams on the concrete deck may experience walking vibration problem. Fatigue, overloading of floor systems and vibrations due to rhythmic activities such as aerobic or dance classes are not within the scope of this annex.

C-2 ANNOYANCE CRITERIA

In the frequency range of 2 to 8 Hz in which people are most sensitive to vibration, the threshold level corresponds approximately to 0.5 percent *g*, where *g* is the acceleration due to gravity. Continuous vibration is generally more annoying than decaying vibration due to damping. Floor systems with the natural frequency less than 8 Hz in the case of floors supporting rhythmic activity and 5 Hz in the case of floors supporting normal human activity should be avoided. However, if it is unavoidable, recommendations of specialist literature may be followed.

C-3 FLOOR FREQUENCY

The fundamental natural frequency can be estimated by assuming full composite action, even in non-composite construction. This frequency, f_1 for a simply supported one way system is given by:

$$f_1 = 156 \sqrt{EI_T / WL^4}$$

where

E = modulus of elasticity of steel, in MPa;

I_T = transformed moment of inertia of the one way system (in terms of equivalent steel) assuming the concrete flange of width equal to the spacing of the beam to be effective, in mm^4;

L = span length, in mm; and

W = dead load of the one way joist, in N/mm.

If the one way joist system is supported by a flexible beam running perpendicular with the natural frequency f_2, the floor frequency may be reduced to f_r, given by:

$$\frac{1}{f_r^2} = \frac{1}{f_1^2} + \frac{1}{f_2^2}$$

C-4 DAMPING

The percentage of critical damping may be assumed approximately as given below:

Sl No. (1)	*System* (2)	*Critical Damping* Percent (3)
i)	Fully composite construction	2
ii)	Bare steel beam and concrete deck	3 to 4
iii)	Floor with finishes, false ceiling, fire proofing, ducts, furniture	6
iv)	Partitions not located along a support or not spaced farther apart than 6 m and partitions oriented in orthogonal directions	Up to 12

C-5 ACCELERATION

The peak acceleration a_o, from heel impact for floors of spans greater than 7m and natural frequency f_1, less than 10 Hz may be calculated as:

$$a_o/g = 600\, f_r / W$$

where

W = total weight of floors plus contents over the span length and equivalent floor width (b), in N;

$b = 40t_s$ ($20\, t_s$ when overhang is only on one side of the beam);

t_s = equivalent thickness of the slab, averaging concrete in slab and ribs; and

g = acceleration due to gravity.

ANNEX D

(*Clause* 14.2.2)

DETERMINATION OF EFFECTIVE LENGTH OF COLUMNS

D-1 METHOD FOR DETERMINING EFFECTIVE LENGTH OF COLUMNS IN FRAMES

In the absence of a more exact analysis, the effective length of columns in framed structures may be obtained by multiplying the actual length of the column between the centres of laterally supporting members (beams) given in Fig. 27 and Fig. 28 with the effective length factor *K*, calculated by using the equations given below, provided the connection between beam and column is rigid type:

a) *Non-sway frames* (*braced frame*) [(*see* **11.1.2** (a)]

A frame is designated as non-sway frame if the relative displacement between the two adjacent floors is restrained by bracings or shear walls (*see* **11.1.2**). The effective length factor, *K*, of column in non-sway frames is given by (*see* Fig. 27):

$$K = \frac{[1 + 0.145(\beta_1 + \beta_2) - 0.265\beta_1\beta_2]}{[2 - 0.364(\beta_1 + \beta_2) - 0.247\beta_1\beta_2]}$$

b) *Sway frames* (*moment resisting frames*) [*see* **11.1.2** (b)]

The effective length factor *K*, of column in sway frames is given by (*see* Fig. 28):

$$K = \left[\frac{1 - 0.2(\beta_1 + \beta_2) - 0.12\beta_1\beta_2}{1 - 0.8(\beta_1 + \beta_2) + 0.6\beta_1\beta_2}\right]^{0.5}$$

where

β_1, β_2 are given, $\beta = \frac{\sum K_c}{\sum K_c + \sum K_b}$

K_c, K_b = Effective flexural stiffness of the columns and beams meeting at the joint at the two ends of the columns and rigidly connected at the joints, and these are calculated by:

$$K_c \text{ and } K_b = C\,(I/L)$$

I = moment of inertia of the member about an axis perpendicular to the plan of the frame,

L = length of the member equal to centre to centre distance of the intersecting member, and

C = correction factor as shown in Table 33.

Table 33 Correction Factors for Effective Flexural Stiffness

(*Clause* D-1)

Sl No.	**Far End Condition**	**Correction Factor, C**	
		Braced Frame	Unbraced Frame
(1)	(2)	(3)	(4)
i)	Pinned	$0.67(1 - \bar{n})$	$0.75(1 - \bar{n})$
ii)	Rigidly connected to column	$0.5(1 - \bar{n})$	$1.5(1 - 0.2\bar{n})$
iii)	Fixed	$1.0(1 - 0.4\bar{n})$	$1.0(1 - 0.4\bar{n})$

NOTE — $\bar{n} = \frac{P}{P_e}$

where

P_e = elastic buckling load, and

P = applied load.

D-2 METHOD FOR DETERMINING EFFECTIVE LENGTH FOR STEPPED COLUMNS (*see* **14.2.2**)

D-2.1 Single Stepped Columns

Effective length in the plane of stepping (bending about axis *z-z*) for bottom and top parts for single stepped column shall be taken as given in Table 34.

NOTE — The provisions of **D-2.1** are applicable to intermediate columns as well with stepping on either side, provided appropriate values of $I_1$and I_2 are taken.

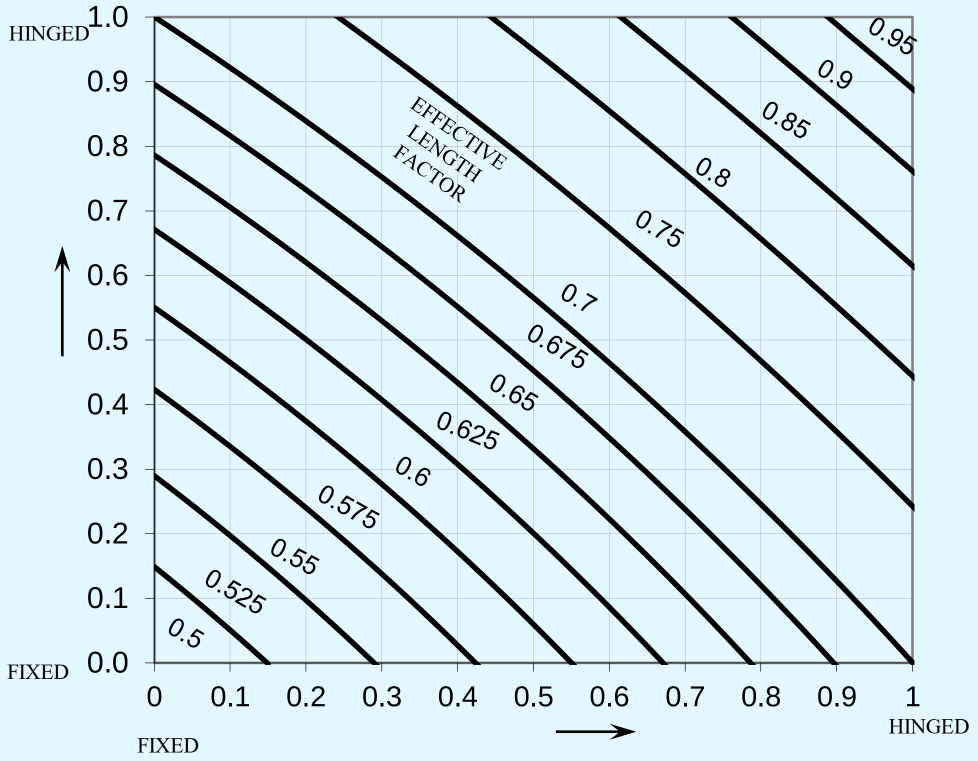

FIG. 27 COLUMN EFFECTIVE LENGTH FACTOR — NON SWAY FRAME

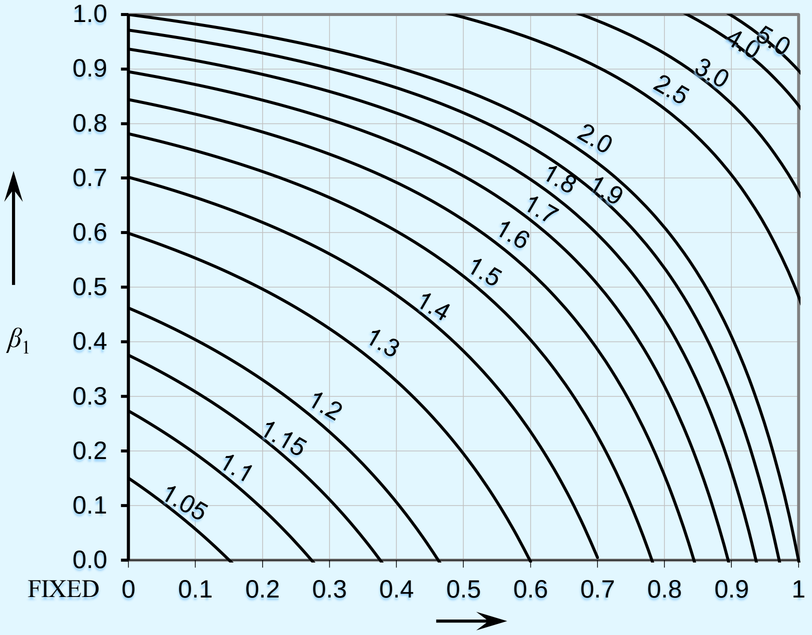

FIG. 28 COLUMN EFFECTIVE LENGTH FACTOR — SWAY FRAME

Table 34 Effective Length of Singled Stepped Columns

(*Clause* D-2.1)

D-3 Effective Length for Double Stepped Columns

Effective lengths in the plane of steppings (bending about axis *z-z*) for bottom, middle and top parts for a double stepped column shall be taken as follows (*see also* Fig. 29):

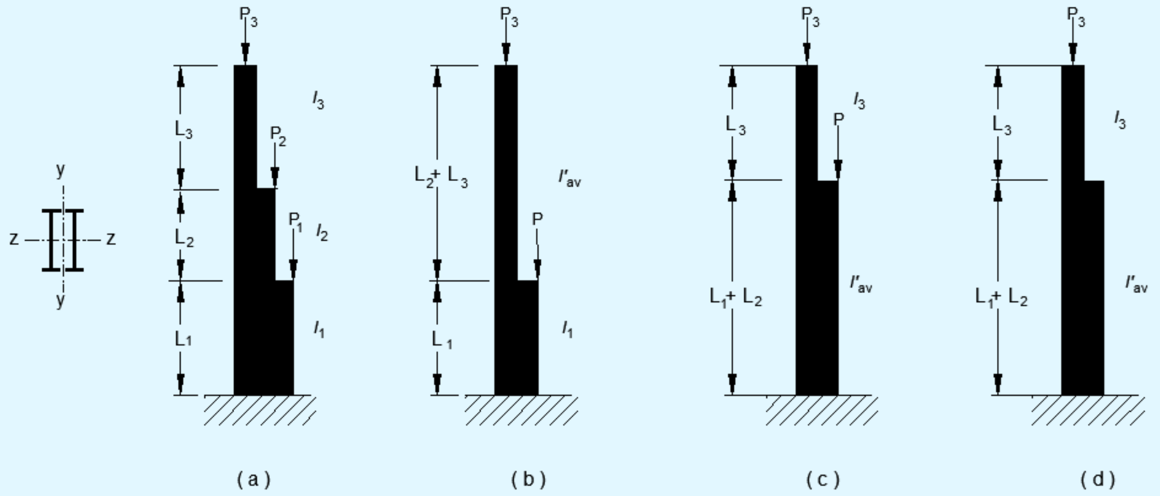

FIG. 29 EFFECTIVE LENGTH OF DOUBLE STEPPED COLUMNS

Coefficient K_1 for effective length of bottom part of double stepped column shall be taken from the formula:

$$K_1 = \sqrt{\frac{t_1 K_1^{\,2} + \left(t_2 K_2^{\,2} + K_3^{\,2}\right) \times \left(1 + n_2\right)^2 \times \dfrac{I_1}{I'_{\text{av}}}}{1 + t_1 + t_2}}$$

where

K_1, K_2, and K_3 are taken from Table 39.

$$t_1 = \frac{P_1}{P_3}, \qquad t_2 = \frac{P_2}{P_3},$$

I'_{av} = average value of moment of inertia for the lower and middle parts

$$= \frac{I_1 L_1 + I_2 L_2}{L_1 + L_2}$$

I'_{av} = average value of moment of inertia for the middle and top parts

$$= \frac{I_2 L_2 + I_3 L_3}{L_2 + L_3}$$

Value of coefficient K_2 for middle part of column is given by formula:

$$K_2 = \frac{K_1}{C_2}, \quad \text{and}$$

Value of coefficient K_3 for the top part of the column is given by:

$$K_3 = \frac{K_1}{C_3} \leq 3$$

where

$$C_2 = \frac{L_2}{L_1}\sqrt{\frac{I_1(P_2+P_3)}{I_2(P_1+P_2+P_3)}}\ ,\ C_3 = \frac{L_3}{L_1}\sqrt{\frac{I_1 P_3}{I_3(P_1+P_2+P_3)}}$$

NOTE — The provisions of **D-3** are applicable to intermediate columns as well with steppings on either side, provided appropriate values of I_1, I_2 and I_3 are taken.

iv)	Effectively held in position and restrained against rotation at bottom end, and top end neither held against rotation nor against translation		$K_1 = 2$	$K_2 = 2$	$K_3 = K_1$ where K_1 is taken from Table 38 with $C_1 = \frac{L_3}{L_1+L_2}\sqrt{\frac{I_{av}}{I_3}}$	

ANNEX E

(*Clause* 15.2.2.1)

ELASTIC LATERAL TORSIONAL BUCKLING

E-1 ELASTIC CRITICAL MOMENT

E-1.1 General

The elastic critical moment is affected by the following:

a) Moment gradient in the unsupported length;

b) Boundary conditions at the lateral support points;

c) Non-symmetric and non-prismatic nature of the member; and

d) Location of transverse load with respect to shear centre.

The boundary conditions at the lateral supports have two components:

1) *Torsional restraint* — where the cross section is prevented from rotation about the shear centre; and

2) *Warping restraint* — where the flanges are prevented from rotating in their own plane about an axis perpendicular to the flange.

The elastic critical moment corresponding to lateral torsional buckling of a doubly symmetric prismatic beam subjected to uniform moment in the unsupported length and torsionally restraining lateral supports is given by:

$$M_{\mathrm{cr}} = \frac{\pi^2 E I_{\mathrm{y}}}{(L_{\mathrm{LT}})^2}\left[\frac{I_{\mathrm{w}}}{I_{\mathrm{y}}} + \frac{G\,I_{\mathrm{t}}\,(L_{\mathrm{LT}})^2}{\pi^2 E\,I_{\mathrm{y}}}\right]^{0.5}$$

where

I_{y}, I_{w}, I_{t} = moment of inertia about the minor axis, warping constant and St.Venant's torsion constant of the cross section, respectively (*see* accepted standards [C-6A(36)] for properties of sections);

G = modulus of rigidity; and

L_{LT} = effective length against lateral torsional buckling (*see* **15.3**).

This equation in simplified form for I-section has been presented in **15.2.2.1**.

While the simplified equation is generally on the safe side, there are many situations where this may be very conservative. More accurate calculation of the elastic critical moment for general case of unsymmetrical sections, tapered members, loading away from shear centre and beams with moment gradient can be obtained from specialist literature, by using an appropriate computer program or equations given below.

E-1.2 Elastic Critical Moment of a Section Symmetrical About Minor Axis

In case of a beam which is symmetrical only about the minor axis, and bending about major axis, the elastic critical moment for lateral torsional buckling is given by the general equation below,

$$M_{\mathrm{cr}} = c_1 \frac{\pi^2 E I_{\mathrm{y}}}{(L_{\mathrm{LT}})^2}\left\{\left[\left(\frac{K}{K_{\mathrm{w}}}\right)^2 \frac{I_{\mathrm{w}}}{I_{\mathrm{y}}} + \frac{G\,I_{\mathrm{t}}\,(L_{\mathrm{LT}})^2}{\pi^2 E\,I_{\mathrm{y}}} + (c_2 y_{\mathrm{g}} - c_3 y_{\mathrm{j}})^2\right]^{0.5} - (c_2 y_{\mathrm{g}} - c_3 y_{\mathrm{j}})\right\}$$

where

c_1, c_2, c_3 = factors depending upon the loading and end restraint conditions (*see* Table 40);

K = effective length factors of the unsupported length accounting for boundary conditions at the end lateral supports. The effective length factor K varies from 0.5 for complete restraint against rotation about weak axis to 1.0 for free rotate about weak axis, with 0.7 for the case of one end fixed and other end free. It is analogous to the effective length factors for compression members with end rotational restraint;

K_w = warping restraint factor. Unless special provisions to restrain warping of the section at the end lateral supports are made, K_w should be taken as 1.0;

y_g = y distance between the point of application of the load and the shear centre of the cross section and is positive when the load is acting towards the shear centre from the point of application;

y_j = $y_s - 0.5\int_A \left(z^2 + y^2\right)^2 y dA/I_z$;

y_s = coordinate of the shear centre with respect to centroid, positive when the shear centre is on the compression side of the centroid; and

y, z = coordinates of the elemental area with respect to centroid of the section.

y_j can be calculated by using the following approximation:

a) *Plain flanges*:

1) $y_j = 0.8 (2\beta_f - 1) h_y /2.0$ (when $\beta_f > 0.5$)
2) $y_j = 1.0 (2\beta_f - 1) h_y /2.0$ (when $\beta_f \leq 0.5$)

b) *Lipped flanges*:

1) $y_j = 0.8 (2\beta_f - 1) (1+ h_L/h) h_y/2$ (when $\beta_f > 0.5$)
2) $y_j = (2\beta_f - 1) (1+ h_L/h) h_y/2$ (when $\beta_f \leq 0.5$)

where

h_L = height of the lip,

h = overall height of the section,

h_y = distance between shear centre of the two flanges of the cross section, and

$\beta_f = I_{fc} /(I_{fc} + I_{ft})$ where I_{fc}, I_{ft} are the moment of inertia of the compression and tension flanges, respectively, about the minor axis of the entire section.

I_t = St. Venant's Torsion constant, given by:

$I_t = \sum b_i t_i^3 /3$ (for open section)

$= 4A_e^{\,2} / \sum (b/t)$ (for hollow section)

where

A_e = area enclosed by the section, and

b, t = breadth and thickness of the elements of the section, respectively.

I_w = The warping constant, given by:

$(1-\beta_f) \beta_f I_y h_y^2$ (for I-sections mono-symmetric about weak axis)= 0 (for angle, Tee, narrow rectangle section and approximately for hollow sections)

ANNEX F

(*Clauses* 11.2.1.2, 15.6.4.2, 17.6.1, 18.10.4.1 *and* 18.11.2.1)

CONNECTIONS

F-1 GENERAL

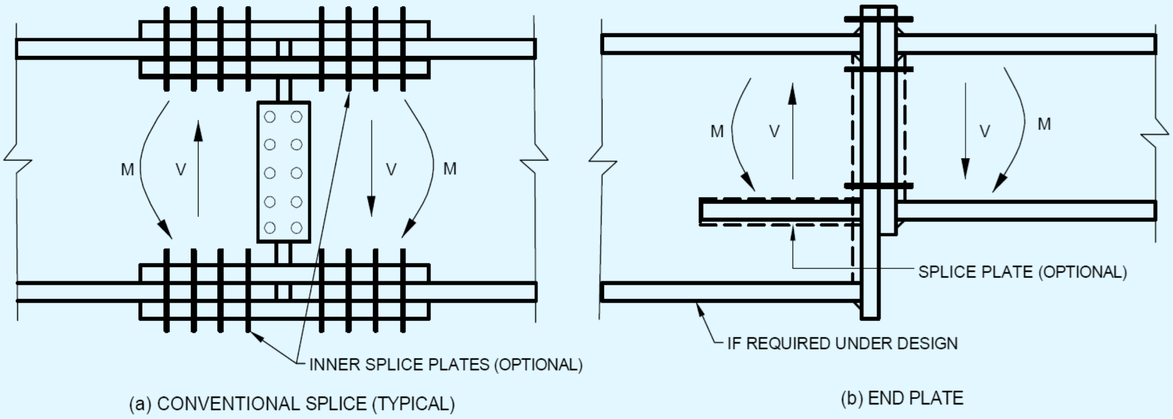
The requirement for the design of splice and beam to column connection as well as recommendation for their design shall be as given below.

F-2 BEAM SPLICES

F-2.1 For rolled section beam splices located away from the point of maximum moment, it may be assumed that the flange splice carries all the moment and the web splice carries the shear (*see* Fig. 30). However, in the case of a deep girder, the total moment may be divided between the flange and the web in accordance with the stress distribution. The web connection should then be designed to resist its share of moment and shear. Even web splice is designed to carry only shear force, the moment about the centroid of the bolt group on either side of the splice should be designed for moment due to eccentricity.

F-2.2 Flange joints should preferably not be located at points of maximum stress. Where splice plates are used, their area shall not be less than 5 percent in excess of the area of the flange element spliced; and their centre of gravity shall coincide, as nearly as possible with that of the element spliced. There shall be enough fasteners on each side of the splice to develop the load in the element spliced plus 5 percent but in no case should the strength developed be less than 50 percent of the effective strength of the material spliced. Wherever possible in welded construction, flange plates shall be joined by complete penetration butt welds. These butt welds shall develop the full strength of the plates. Whenever the flange width or thickness changes at the splice location, gradual transition shall be made in the width/thickness of the larger flange.

F-2.3 When beam splice is located at the point of inflection of a continuous beam, the flange splicing requirement given above may be relaxed appropriately.



(a) CONVENTIONAL SPLICE (TYPICAL)

(b) END PLATE

FIG. 30 BEAM SPLICES

F-3 COLUMN SPLICE

F-3.1 Where the ends of compression members are faced for bearing over the whole area, they shall be spliced to hold the connected parts aligned. The ends of compression members faced for bearing shall invariably be machined to ensure perfect contact of surfaces in bearing (*see* Fig. 31).

F-3.2 Where such members are not faced for complete bearing the splices shall be designed to transmit all the forces to which the members is subjected at the splice location.

F-3.3 Wherever possible, splices shall be proportioned and arranged so that centroidal axis of the splice coincides as nearly as possible with the centroidal axes of the members joined, in order to avoid eccentricity; but where eccentricity is present in the joint, the resulting stress considering eccentricity shall be provided for.

F-3.4 If a column flange is subjected to significant tension or if the faces are not prepared for bearing, or if full continuity is required without slip, only HSFG bolts shall be used.

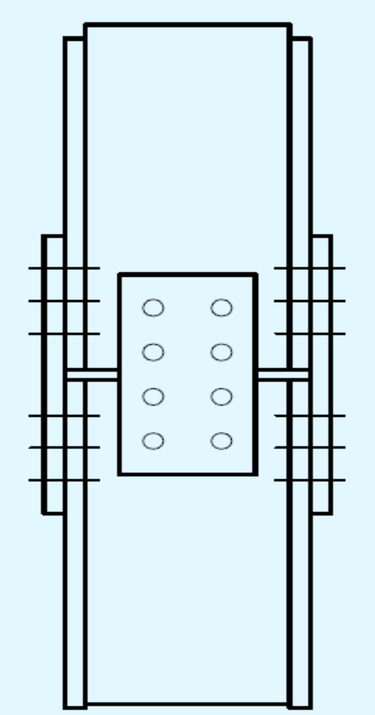


FIG. 31 COLUMN SPLICE
(TYPICAL)

F-4 BEAM-TO-COLUMN CONNECTIONS

F-4.1 Simple Connections

Simple connections are assumed to transfer only shear at some nominal eccentricity and typically used in frames up to about five stories in height, where strength rather than stiffness govern the design. In such frames separate lateral load resisting system is to be provided in the form of bracings or shear walls. The connections shown in Fig. 32 (A), Fig. 32 (B), Fig. 32 (C) and Fig. 32 (D) can be assumed as simple connections in framed analysis and need to be checked only for the transfer of shear from beam to column.

F-4.2 Rigid Connections

In high-rise and slender structures, stiffness requirements may warrant the use of rigid connections. Rigid connections transfer significant moments to the columns and are assumed to undergo negligible deformations at the joint. These are necessary in sway frames for stability and also contribute in resisting lateral loads. The connections shown in Fig. 32 (E), Fig. 32 (F), Fig. 32 (G) can be assumed as rigid connection in frame analysis and need to be checked for both shear and moment transfer from beam to the column. Fully welded connections can also be considered as rigid beam to column connections.

32 H HEADER PLATE

FIG. 32 SIZE PARAMETER FOR VARIOUS TYPES OF CONNECTION

F-4.3 Semi-Rigid Connections

Semi-rigid connections fall between the two types mentioned above. The fact is that simple connections do have some degree of rotational rigidity as in the semi-rigid connections. Similarly, rigid connections do experience some degree of joint deformation and this can be utilized to reduce the joint design moments.

The moment-rotation relationship of the connections have to be determined based on experiments conducted for the specific design or based on the relationship derived from tests, presented in specialist literature. The simplest method of analysis will be to idealize the connection as an equivalent rotational spring with either a bilinear or non-linear moment-rotation characteristics. The classification proposed by Bjorhovde combined with the Frye-Morris model can be used with convenience to model semi-rigid connections, as given in the next section.

F-4.3.1 *Connection Classification*

Connections are classified according to their ultimate strength or in terms of their initial elastic stiffness and Bjorhovde's classification. It is based on the non-dimensional moment parameter ($m^1 = M_u / M_{pb}$) and the non-dimensional rotation parameter ($\theta^1 = \theta_r/\theta_p$), where θ_p is the plastic rotation. The Bjorhovde's classification is based on a reference length of the beam equal to 5 times the depth of the beam. The limits used for connection classification are shown in Table 41 and are graphically represented in Fig. 33.

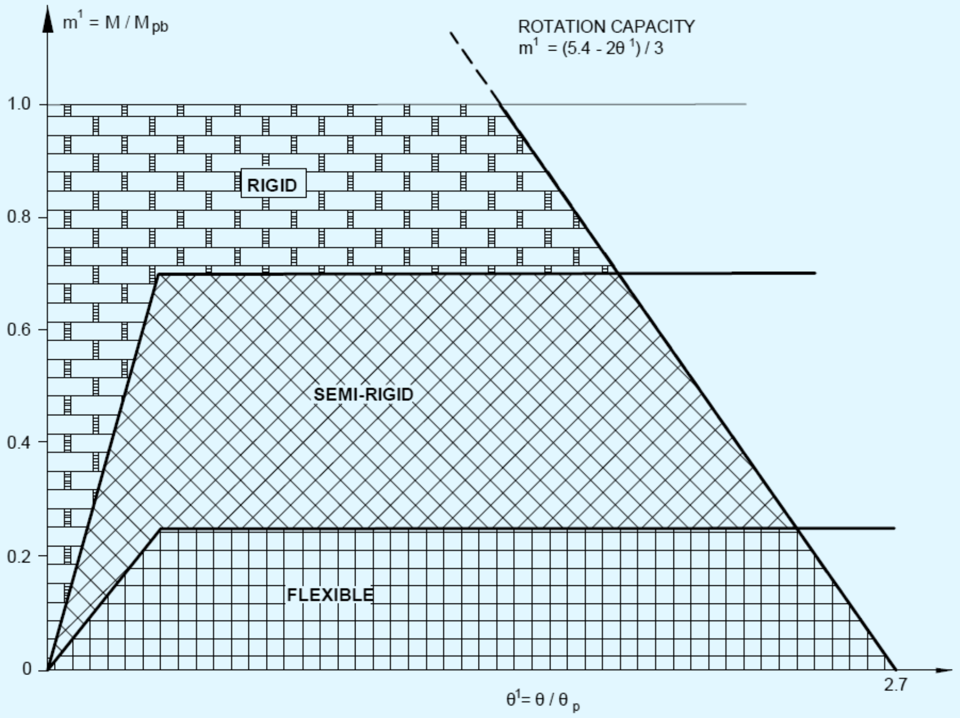

FIG. 33 CLASSIFICATION OF CONNECTIONS ACCORDING TO BJORHOVDE

F-4.3.2 *Connection Models*

Frye-Morris has derived the following polynomial model for the moment curvature relationship of semi-rigid connections:

$$\theta_r = C_1(KM)^1 + C_2\,(KM)^3 + C_3\,(KM)^5$$

where

M = moment at the joint, in kN.m;

K = standardization parameter which depend on the connection type and geometry; and

C_1, C_2, C_3 = curve fitting constants Table 42 shows the curve fitting constants and standardization constants for Frye-Morris Model [All size parameters in the table are in mm, (*see* Fig. 32)].

Table 41 Connection Classification Limits

(*Clause* F-4.3.1)

Sl No. (1)	Nature of the Connection (2)	In Terms of Strength (3)	In Terms of Stiffness (4)
i)	Rigid connection	$m^1 \geq 0.7$	$m^1 \geq 2.5\theta^1$
ii)	Semi-rigid connection	$0.7 > m^1 > 0.2$	$2.5\theta^1 > m^1 > 0.5\theta^1$
iii)	Flexible connection	$m^1 \leq 0.2$	$m^1 \leq 0.5\theta^1$

Table 42 Connection Constants in Frye-Morris Model

(*Clause* F-4.3.2)

Sl No. (1)	Type (2)	Connection Type (3)	Curve-Fitting Constants (4)	Standardization Constants (5)
i)	A	Single web angle connection	$C_1 = 1.91 \times 10^4$ $C_2 = 1.30 \times 10^{11}$ $C_3 = 2.70 \times 10^{17}$	$K = d_a^{-2.4} t_c^{-1.81} g^{0.15}$
ii)	B	Double web angle connection	$C_1 = 1.64 \times 10^3$ $C_2 = 1.03 \times 10^{14}$ $C_3 = 8.18 \times 10^{25}$	$K = d_a^{-2.4} t_c^{-1.81} g^{0.15}$
iii)	C	Top and seat angle connection with double web angle	$C_1 = 2.24 \times 10^{-1}$ $C_2 = 1.86 \times 10^4$ $C_3 = 3.23 \times 10^8$	$K = d^{-1.287} t_a^{-1.128} t_c^{-0.415}$ $l_a^{-0.694} (g - 0.5 d_b)^{1.35}$
iv)	D	Top and seat angle connection without double web angle	$C_1 = 1.63 \times 10^3$ $C_2 = 7.25 \times 10^{14}$ $C_3 = 3.31 \times 10^{23}$	$K = d^{-1.5} t_a^{-0.5} l_a^{-0.7} d_b^{-1.1}$
v)	E	End plate connection without column stiffeners	$C_1 = 1.78 \times 10^4$ $C_2 = -9.55 \times 10^{16}$ $C_3 = 5.54 \times 10^{29}$	$K = d_g^{-2.4} t_p^{-0.4} t_f^{-1.5}$
vi)	F	End plate connection with column stiffeners	$C_1 = 2.60 \times 10^2$ $C_2 = 5.37 \times 10^{11}$ $C_3 = 1.31 \times 10^{22}$	$K = d_g^{-2.4} t_p^{-0.6}$
vii)	G	T-stub connection	$C_1 = 4.05 \times 10^2$ $C_2 = 4.45 \times 10^{13}$ $C_3 = -2.03 \times 10^{23}$	$K = d^{-1.5} t_f^{-0.5} l_t^{-0.7} d_b^{-1.1}$

Table 42 (*Concluded*)

Sl No. (1)	Type (2)	Connection Type (3)	Curve-Fitting Constants (4)	Standardization Constants (5)
viii)	H	Header-plate connection	$C_1 = 3.87$ $C_2 = 2.71 \times 10^5$ $C_3 = 6.06 \times 10^{11}$	$K = t_p^{-1.6} g^{1.6} d_b^{-2.3} t_w^{-0.5}$

where

d = depth, in mm, of beam;

d_a = depth, in mm, of the angle;

d_b = diameter, in mm, of the bolt;

d_g = centre, in mm, to centre of the outermost bolt of the end plate connection;

g = gauge, in mm, distance of bolt line;

t_a = thickness, in mm, of the top angle;

t_c = thickness, in mm, of the web angle;

t_f = thickness, in mm, of flange T-stub connector;

t_w = thickness, in mm, of web of the beam in the connection;

t_p = thickness, in mm, of end plate, header plate;

l_a = length, in mm, of the angle; and

l_t = length, in mm of the T-stub connector.

NOTE — For preliminary analysis using a bilinear moment curvature relationship, the stiffness given in Table 43 may be assumed depending on the type of connection. The values are based on the secant stiffness at a rotation of 0.01 radian and typical dimension of connecting angle and other components as given in the table.

Table 43 Secant Stiffness

(*Table 42*)

SI No. (1)	Type of Connection (2)	Dimension mm (3)	Secant Stiffness kNm/Radian (4)
i)	Single web connection angle	$d_a = 250$, $t_a = 10$, $g = 35$	1 150
ii)	Double web-angle connection	$d_a = 250$, $t_a = 10$, $g = 77.5$	4 450
iii)	Top and seat angle connection without double web angle connection	d_a=300, t_a=10, l_a=140, d_b=20	2 730
iv)	Header plate	$d_p = 175$, $t_p = 10$, $g = 75$, $t_w = 7.5$	2 300

F-5 COLUMN BASES

F-5.1 Base Plates

Columns shall be provided with base plates capable of distributing the compressive forces in the compressed parts of the column over a bearing area such that the bearing pressure on the foundation does not exceed the design strength of the point. The design strength of the joint between the base plate and the foundation shall be determined taking account of the material properties and dimensions of both the grout and the concrete foundation.

F-5.2 Holding Down Bolts (Anchor Bolts)

F-5.2.1 Holding down bolts shall be provided if necessary to resist the effects of the design loads. They shall be designed to resist tension due to uplift forces and tension due to bending moments as appropriate.

F-5.2.2 When calculating the tension forces due to bending moments, the lever arm shall not be taken as more than the distance between the centroid of the bearing area on the compression side and the centroid of the bolt group on the tension side, taking the tolerances on the positions of the holding down bolts into account.

F-5.2.3 Holding down bolts shall either be anchored into the foundation by a hook or by a washer plate or by some other appropriate load distributing member embedded in the concrete.

F-5.2.4 If no special elements for resisting the shear force are provided, such as block or bar shear connectors, it shall be demonstrated that sufficient resistance to transfer the shear force between the column and the foundation is provided by one of the following:

a) Frictional resistance of the joint between the base plate and the foundation;

b) Shear resistance of the holding down bolts;

c) Shear resistance of the surrounding part of the foundation; and

d) Shear and bearing resistance of the shear key plates welded to the base plate and embedded in the pedestal/foundation.

ANNEX G

(*Foreword*)

PLATE GIRDERS WITH CORRUGATED WEB

G-1 FLEXURAL RESISTANCE

The overhang of the flange beyond the farthest face of the web at any section may be limited to that required by class 1, 2 and 3 sections, as given in Table 2. Contribution of web in flexural resistance is disregarded as given below.

The flexural design resistance is given by

$$M_d = Min\left\{\frac{b_c t_c f_{fc}}{\gamma_{m0}}\left(h_w + \frac{t_t + t_c}{2}\right); \frac{b_t t_t f_{ft}}{\gamma_{m0}}\left(h_w + \frac{t_t + t_c}{2}\right)\right\}$$

where

The dimensional symbols are shown in Fig. 34.

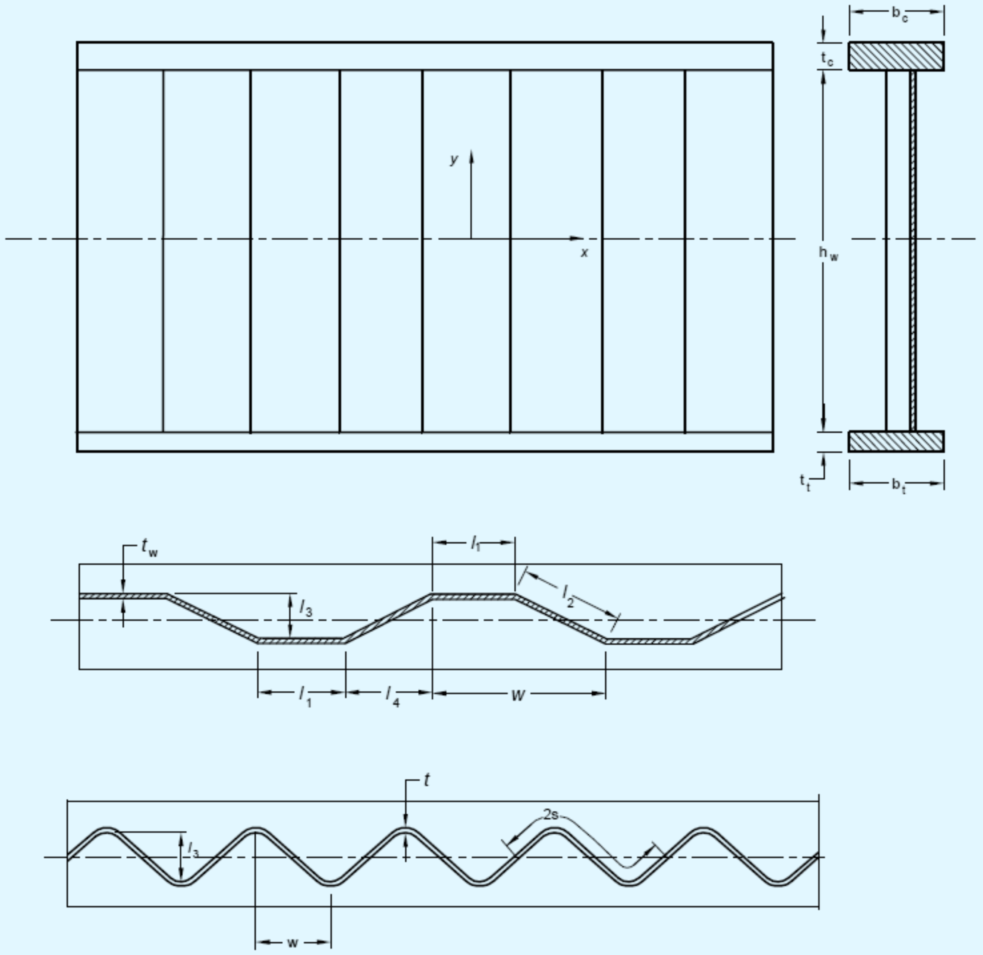

FIG. 34 ELEMENT DIMENSIONS OF PLATE GIRDER WITH CORRUGATED WEB

The design compressive stress, f_{fc}, is the minimum of yielding compressive stress after accounting for transverse (in-plane) bending of compression flange due to eccentric shear flow in the flange due to corrugated web as given below, or by lateral buckling of compression flange as given in **15.2.2**.

The yield strength after accounting for eccentric shear flow in the flanges is given by

$$f_{fc} = f_{yc}\sqrt{1 - \frac{4 M_{vc}\gamma_{m0}}{b_c^2 t_c f_{yc}}}\ ; \qquad f_{ft} = f_{yt}\sqrt{1 - \frac{M_{vt}\gamma_{m0}}{M_{Pf}}}$$

where

f_{yc}, f_{yt} = Yield strength of the material in the tension and compression flanges respectively

M_{Pf} = Ultimate design resistance of the flange under in in-plane bending

= $t\, b^3\, f_{yf}/4$ for plastic and compact flanges, $t\, b^3\, f_{yf}/6$ for semi compact flanges

M_{vc}, M_{vt} = in-plane transverse bending moment in the tension and compression flange, respectively due to eccentric shear force from the web as shown in Fig. 35, and is evaluated from

$$M_{vc} = \frac{V\, y_c b_c\, t_c\, l_1 l_3}{2I_z}; \qquad M_{vt} = \frac{V\, y_t b_t\, t_t\, l_1 l_3}{2I_z}$$

where

V = Shear force at the section of the girder;

I_z = Moment of inertia about the major axis of the section disregarding the corrugated web; and

y_c, y_t = Distance of the centroid of the compression and tension flange, respectively, from the neutral axis of the girder.

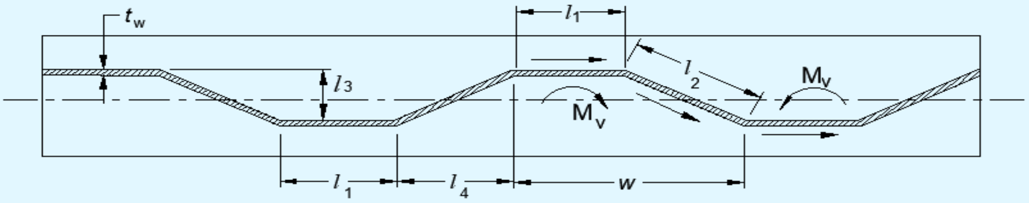

FIG. 35 IN-PLANE TRANSVERSE BENDING MOMENT IN FLANGES DUE TO ECCENTRIC SHEAR FLOW FROM WEB

G-2 SHEAR RESISTANCE

The design shear resistance of the web, V_d, is given by

$$V_d = V_n/\gamma_{m0}$$

where

$$V_n = h_w\, t_w\, \chi_v\, f_{yw}/\sqrt{3}$$

where

h_w, t_w, f_{yw} = depth, thickness and yield strength of the web;

χ_v = shear stress reduction factor to account for web buckling, and is the smallest of local buckling χ_{vl}, global buckling, χ_{vg}, or interaction buckling, χ_{vlg}, of the web under shear, evaluated as given below; and

χ_v = min (χ_{vl}, χ_{vg}, χ_{vlg}).

The shear stress reduction factor for local buckling of the web is evaluated as,

$\chi_{vl} = 1.0$ when $\lambda_{wl} \leq 0.8$,
$\chi_{vl} = [1 - 0.8(\lambda_{wl} - 0.8)]$ when $0.8 < \lambda_{wl} < 1.2$,
$\chi_{vl} = \frac{1}{\sqrt{3}\lambda_{wl}^2}$ when $\lambda_{wl} \geq 1.2$,

where

$$\lambda_{wl} = \sqrt{f_{yw}/(\sqrt{3}\tau_{cr,l})}$$

$$\tau_{cr,l} = \frac{k_v \pi^2 E}{12(1-\mu^2)\,(h_w/t_w)^2}$$

$$k_v = 4.0 + 5.35\left(\frac{c}{h_w}\right) \quad \text{when } (c/h_w) < 1.0$$

$$k_v = 5.35 + 4.0\left(\frac{c}{h_w}\right) \quad \text{when } (c/h_w) \geq 1.0$$

where

c is larger of l_1 and l_2 of corrugated web (*see* Fig. 35).

In case of sinusoidally corrugated webs $\tau_{cr,e}$ may be evaluated using:

$$\tau_{cr,l} = \left(5.35 + \frac{l_3\, s}{h_w t_w}\right)\frac{\pi^2 E}{12(1-\mu^2)(s/t_w)^2}$$

The shear stress reduction factor for global buckling of the web is evaluated as:

$$\chi_{vg} = \frac{1.5}{(0.5+\lambda_{wg}^2)} \leq 1.0$$

$$\lambda_{wg} = \sqrt{f_{\mathrm{yw}}/(\sqrt{3}\tau_{\mathrm{cr,g}})}$$

$$\tau_{cr,g} = \frac{32.4}{t_w h_w^2}\sqrt[4]{D_x D_z^3}$$

$$D_x = \frac{Et_w^3}{12(1-\mu^2)}\frac{w}{s} \text{ for sinusoidal corrugation}$$

$$D_x = \frac{Et_w^3}{12(1-\mu^2)}\frac{w}{(l_1+l_2)} \text{ for profiled corrugation}$$

$$D_z = \frac{EI_z}{w}$$

I_z = second moment of area of one corrugation of length w

The shear stress reduction factor for global buckling of the web is evaluated as:

$$\chi_{vlg} = \frac{\chi_{vl} \times \chi_{vg}}{\sqrt{{\chi_{vl}}^2 + {\chi_{vg}}^2}} \leq 1.0$$

The reduction in shear resistance of the web due to the moment at the section need not be considered, since its contribution to flexure is not considered.

G-3 RESISTANCE TO CONCENTRATED LOAD

The design for bearing resistance under concentrated load and reactions may be carried out as required in **15.7**.

ANNEX H

(*Clause* 24.16)

GENERAL RECOMMENDATIONS FOR STEELWORK TENDERS AND CONTRACTS

H-1 GENERAL

H-1.1 The recommendations given in this annex are in line with those generally adopted for steelwork construction and are meant for general information.

H-1.2 These recommendations do not form part of the requirements of the Section and compliance with these is not necessary for the purpose of complying with this Section.

H-1.3 The recommendations are unsuitable for inclusion as a block requirement in a contract, but in drawing up a contract the points mentioned should be given consideration.

H-2 EXCHANGE OF INFORMATION

Before the steelwork design is commenced, the building designer should be satisfied that the planning of the building, its dimensions and other principal factors meet the requirements of the building owner and comply with regulations of all authorities concerned. Collaboration of building designer and steelwork designer should begin at the outset of the project by joint consideration of the planning and of such questions as the stanchion spacing, materials to be used for the construction, and depth of basement.

H-3 INFORMATION REQUIRED BY THE STEELWORK DESIGNER

H-3.1 General

Site plans showing in plan and elevation of the proposed location and main dimensions of the building or structure;

a) Ground levels, existing and proposed;

b) Particulars of buildings or other constructions which may have to remain on the actual site of the new building or structure during the erection of the steelwork;

c) Particulars of adjacent buildings affecting, or affected by, the new work;

d) Stipulation regarding the erection sequence or time schedule;

e) Conditions affecting the position or continuity of members;

f) Limits of length and weight of steel members in transit and erection;

g) Drawings of the substructure, proposed or existing, showing:

    1) levels of stanchion foundations, if already determined;

    2) any details affecting the stanchion bases or anchor bolts;

    3) permissible bearing pressure on the foundation; and

    4) provisions for grouting.

NOTE — In the case of new work, the substructure should be designed in accordance with the relevant standards dealing with foundations and substructure.

h) The maximum wind velocity appropriate to the site (*see* Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS); and

j) Environmental factors, such as proximity to sea coast, and corrosive atmosphere. Reference to bye-laws and regulations affecting the steelwork design and construction.

H-3.2 Further Information Relating to Buildings

a) Plans of the floors and roof with principal dimensions, elevations and cross sections showing heights between floor levels;

b) The occupancy of the floors and the positions of any special loads should be given;

c) The building drawings, which should be fully dimensioned, should preferably be to the scale of 1 to 100 and should show all stairs, fire escapes, lifts, etc, suspended ceilings, flues and ducts for heating and ventilating. Doors and windows should be shown, as the openings may be taken into account in the computations of dead load;

    1) Requirements should be given in respect of any maximum depth of beams or minimum head room; and

    2) Large-scale details should be given of any special features affecting the steelwork.

d) The inclusive weight per m^2 of walls, floors, roofs, suspended ceilings, stairs and partitions, or particulars of their construction and finish for the computation of dead load;

    1) The plans should indicate the floors, which are to be designed to carry partitions. Where the layout of partitions is not known, or a given layout is liable to alteration, these facts should be specially noted so that allowance may be made for partitions in any position (*see* Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS).

e) The superimposed loads on the floors appropriate to the occupancy, as given in Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS or as otherwise required;

f) Details of special loads from cranes, runways, tips, lifts, bunkers, tanks, plant and equipment; and

g) The grade of fire resistance appropriate to the occupancy as may be required.

H-4 INFORMATION REQUIRED BY TENDERER (IF NOT ALSO DESIGNER)

H-4.1 General

All information listed under H-3.1;

a) Climatic conditions at site-seasonal variations of temperature, humidity, wind velocity and direction;

b) Nature of soil. Results of the investigation of sub-soil at site of building or structure;

c) Accessibility of site and details of power supply;

d) Whether the steelwork contractor will be required to survey the site and set out or check the building or structure lines, foundations and levels;

e) Setting-out plan of foundations, stanchions and levels of bases;

f) Cross sections and elevations of the steel structure, as necessary, with large-scale details of special features;

g) Whether the connections are to be bolted, riveted or welded. Particular attention should be drawn to connections of a special nature, such as turned bolts, high strength friction grip bolts, long rivets and overhead welds;

h) Quality of steel, and provisions for identification;

j) Requirements in respect of protective paintings at works and on site, galvanizing or cement wash;

k) Approximate dates for commencement and completion of erection;

m) Details of any tests which have to be made during the course of erection or upon completion; and

n) Schedule of quantities. Where the tenderer is required to take off quantities, a list should be given of the principal items to be included in the schedule.

H-4.2 Additional Information Relating to Buildings

a) Schedule of stanchions giving sizes, lengths and typical details of brackets, joints, etc;

b) Plan of grillages showing sizes, lengths and levels of grillage beams and particulars of any stiffeners required;

c) Plans of floor beams showing sizes, lengths and levels eccentricities and end moments. The beam reactions and details of the type of connection required should be shown on the plans;

d) Plan of roof steelwork. For a flat roof, the plan should give particulars similar to those of a floor plan. Where the roof is pitched, details should be given of trusses, portals, purlins, bracing, etc;

e) The steelwork drawings should preferably be to a scale of 1 to 100 and should give identification marks against all members; and

f) Particulars of holes required for services, pipes, machinery fixings, etc Such holes should preferably be drilled at works.

H-4.3 Information Relating to Execution of Building Work

a) Supply of materials;

b) Weight of steelwork for payment;

c) Wastage of steel;

d) Insurance, freight and transport from shop to site;

e) Site facilities for erection;

f) Tools and plants;

g) Mode and terms of payment;

h) Schedules;

j) Force majeure (sections and provisions for liquidation and damages for delay in completion); and

k) Escalation sections.

H-5 DETAILING

In addition to the number of copies of the approved drawings or details required under the contract, dimensioned shop drawings or details should be submitted in duplicate to the engineer who should retain one copy and return the other to the steel supplier or fabricators with his comments, if any.

H-6 TIME SCHEDULE

As the dates on which subsequent trades can commence, depend on the progress of erection of the steel framing, the time schedule for the latter should be carefully drawn up and agreed to by the parties concerned at a joint meeting.

H-7 PROCEDURE ON SITE

The steelwork contractor should be responsible for the positioning and levelling of all steelwork. Any checking or approval of the setting out by the general contractor or the engineer should not relieve the steelwork contractor of his responsibilities in this respect.

H-8 INSPECTION

References may be made to the good practice [C-6A(44)] for general guidance.

H-8.1 Access to Contractor’s Works

The contractor should offer facilities for the inspection of the work at all stages.

H-8.2 Inspection of Fabrication

Unless otherwise, agreed, the inspection should be carried out at the place of fabrication. The contractor should be responsible for the accuracy of the work and for any error, which may be subsequently discovered.

H-8.3 Inspection on Site

To facilitate inspection, the contractor should during all working hours, have a foreman or properly accredited charge hand available on the site, together with a complete set of contract drawings and any further drawings and instructions which may have been issued from time to time.

H-9 MAINTENANCE

H-9.1 General

Where steelwork is to be encased in solid concrete, brickwork or masonry, the question of maintenance should not arise, but where steelwork is to be housed in hollow fire protection or is to be unprotected, particularly where the steelwork is exposed to a corroding agent, the question of painting or protective treatment of the steelwork should be given careful consideration at the construction stage, having regard to the special circumstances of the case.

H-9.2 Connections

Where connections are exposed to a corroding agent, they should be periodically inspected, and any corroded part should be thoroughly cleaned and painted.

Where bolted connections are not solidly encased and are subject to vibratory effects of machinery or plant, they should be periodically inspected and all bolts tightened.

LIST OF STANDARDS

The following list records those standards which are acceptable as 'good practice' and 'accepted standards' in the fulfilment of the requirements of this NBCS. The latest version of a standard shall be adopted at the time of enforcement of this NBCS. The standards listed may be used by the Authority as a guide in conformance with the requirements of the referred clauses in this NBCS.

In the following list, the number appearing in the first column within parentheses indicates the number of the reference in this Subsection of this NBCS.

National Building Code Sectional Committee, CED 46

FOREWORD

This NBCS (Part C/Subsection 6B) covers the composite construction consists of the use of prefabricated steel structural units like steel beams and steel open web joists (trusses) in combination with concrete elements and often with steel reinforcements.

The design and construction should ensure monolithic action between the structural steel and concrete components so that they act as a single structural unit.

The Section 6 'Steel' was first published in 1970 and was subsequently revised in 1983, 2005 and 2016 as a chapter of the National Building Code of India. In the second revision in 2005, the detailed design provisions were not included as IS 800 : 1984 'Code of practice for general construction in steel (*second revision*)'was under revision at that time. This Section, therefore, then referred to the 1984 version of IS 800 with the remarks that the latest version would prevail, as and when published. It, however, covered the philosophical aspects of limit state design which was being introduced in the revision of IS 800. IS 800 was subsequently revised and published as IS 800 : 2007 and hence, became the prevailing version for use under this Section. In the third revision of 2016, the Section 6 was brought in line with the revised version of IS 800 : 2007 and its amendment No. 1 and to take care of further improvements and incorporations required.

In the current revision, this publication has been renamed as National Building Construction Standards (NBCS).

In this revision of Section 6, the Section has been subdivided into the following subsections with the chapter on 'composite construction in structural steel and concrete' being introduced for the first time:

a) 6A Steel; and

b) 6B Composite construction in structural steel and concrete.

The provisions of this Subsection (Part C/Subsection 6B) are largely based on IS 11384 : 2022 'Composite construction in structural steel and concrete — Code of practice (*first revision*)'. The growing use of steel-concrete composites in building construction necessitated this new chapter in this NBCS.

The provisions of this Subsection conform to the limit state design philosophy, ensuring consistency with IS 456 : 2000 'Plain and reinforced concrete — Code of practice' for reinforced concrete and Part C/Sec 6A for structural steel. The Subsection includes comprehensive provisions for the design of key structural components such as beams, slabs, and columns in composite construction. It specifically addresses two types of composite columns — Concrete-encased steel columns, which may be either fully or partially encased, and concrete-filled steel columns — Both of which enhance load-bearing capacity and fire resistance. For composite slabs, the Subsection includes two types: profiled sheeting, which serves as formwork for reinforced concrete, and embossed profile sheeting, which functions as both formwork and tension reinforcement, with or without shear connectors. It also provides guidelines for the design and testing of shear connectors to ensure efficient load transfer. Serviceability limit states regulate deflection, vibration, and fire performance. Additionally, the subsection includes specifications for light gauge steel and lightweight concrete, broadening the scope of composite construction applications. This subsection is restricted to the design of steel-concrete composite components and systems used in buildings.

Though the common methods of designs have been covered in this NBCS, special systems of design and construction, not covered by this NBCS, may be permitted on production of satisfactory evidence regarding their design adequacy and safety based on specialist literature or by analysis, test, or both.

All requirements of Part C/Sec 6A in so far as they apply, shall be deemed to form a part of this subsection, except where otherwise laid down in this subsection.

All standards, whether given herein above or cross-referred to in the main text of this Section, are subject to revision. The parties to agreement based on this Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

As the regulation of land development and buildings is a State subject and is dealt by the States and local bodies such as urban local bodies within their jurisdiction through building regulatory documents like building regulations, building byelaws, and fire regulations, this document is voluntary in nature and is non-binding. The implementation depends on adoption by concerned parties or stipulations in a contract or by appropriate adoption by the concerned authorities.

For the purpose of deciding whether a particular requirement of this Subsection is complied with the final value, observed or calculated, expressing the result of a test or analysis shall be rounded off in accordance with IS 2 : 2022 'Rules for rounding off numerical values (*second revision*)'. The number of significant places retained in the rounded-off value should be the same as that of the specified value in this Subsection.

This Page has been Intentionally left blank

Important Explanatory Note for Users of the NBCS

In any Part/Section of this NBCS, where reference is made to **‘good practice’** in relation to design, constructional procedures or other related information, and where reference is made to **‘accepted standard’** in relation to material specification, testing, or other related information, the Indian Standards listed at the end of the Part/Section shall be used as a guide to the interpretation.

At the time of publication, the editions indicated in the standards were valid. All standards are subject to revision and parties to agreements based on any Part/Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

In the list of standards given at the end of a Part/Section, the number appearing within parentheses in the first column indicates the number of the reference of the standard in the Part/Section. For example:

a) Good practices [C-6B(1)] refers to the Indian Standard(s) give at serial number (1) of the list of standards given at the end of this Part C/Subsection 6B, that is, IS 456 : 2000 ‘Plain and reinforced concrete — Code of practice (*fourth revision*)’ and IS 800 : 2007 ‘General construction in steel — Code of practice (*third revision*)’; and

b) Accepted standards [C-6B(4)] refers to the Indian Standards given at serial number (4) of the list of standards given at the end of this Part C/Subsection 6B, that is, IS 2062 (Part 1) : 2025 'Structural steel: Part 1 Hot rolled medium and high tensile steel (*eighth revision*)'.

NATIONAL BUILDING CONSTRUCTION STANDARDS

PART C STRUCTURAL DESIGN

SECTION 6 STEEL AND COMPOSITE CONSTRUCTION

6B COMPOSITE CONSTRUCTION IN STRUCTURAL STEEL AND CONCRETE

1 SCOPE

1.1 This NBCS (Part C/Subsection 6B) deals with the design and construction of composite structures made up of structural steel and cast-in-situ/precast concrete, joined together to act integrally.

1.2 This Subsection is applicable to simply supported as well as continuous beams slabs and supporting column systems. The design provisions in this code are based on the limit states method of design.

2 -

NOTE — This clause is intentionally left blank.

3 TERMINOLOGY

For the purpose of this Subsection, the definitions given in as per good practices [C-6B(1)] and the following shall apply.

3.1 Accidental Load — The load is not normally expected in design life but has a major impact if it ever occurs, such as ramming of vehicles against columns or any other member of the frame like bracings, blast loading, etc.

3.2 Accompanying Load — Imposed load acting along with leading imposed load but causing lower action and/or deflections.

3.3 Action — The primary cause for stress or deformations in a structure, such as dead, imposed, wind, seismic, or temperature loads.

3.4 Built-up Section — A member fabricated by inter-connecting more than one element to form a compound section acting as a single member.

3.5 Camber — intentionally introduced pre-curving (generally upwards) in a system, member or any portion of a member with respect to its chord. These are generally introduced to compensate for deflections at a specific level of loads.

3.6 Composite Action — Integral action of primary supporting steel member and supported concrete deck with or without limited slip at their interface to ensure greater strength and rigidity. In composite columns, it is the integral action between steel and its encasement or infill concrete. The shear transfer is to be ensured through the use of mechanical devices known as shear connectors in composite beams and columns, as required (*see* Fig. 8).

3.7 Design Load/Factored Load — A load value obtained by multiplying the characteristic load with the partial safety factor for loads.

3.8 Design Service Life — The time period during which the structure or its components should satisfy the design objectives and functions.

3.9 Detail Category — Designation given to a particular detail to indicate the S-N curve to be used in fatigue assessment.

3.10 Differential Shrinkages — It is entirely due to shrinkage of concrete from the time composite action comes into effect. When the coefficient of thermal expansion varies significantly between steel and concrete (concrete with limestone or granite aggregate), it also includes the difference in thermal strain between the steel and concrete. Differential shrinkage may lead to an increase in stresses and is more pronounced in continuous beams.

3.11 Fatigue — Damage caused by repeated fluctuations of stress, leading to progressive cracking of a structural element.

3.12 Fatigue Limit State — The state of failure through fatigue damage due to repeated application of loads.

3.13 Fatigue Strength — Stress range that can be endured by a category of detail, depending upon the number of cycles.

3.14 Flexible Shear Connector — It resists shear forces by bending, tension or shearing in the root at the connection point of the steel member. It is subjected to plastic deformations as it reaches the ultimate strength, and the failure mode is ductile. It consists of studs, channels, etc (Fig. 8) welded to steel members to develop composite action with the concrete.

3.15 Initial Dead Load — The combination of weight of steel structure and the portion of the concrete deck that is supported by the steel structure alone before the development of full composite action with concrete reaching 75 percent of its 28 days strength.

3.16 Limit State — The load state beyond which the structure is incapable of performing its desired function.

3.17 Loads — Applied forces as per loads indicated in relevant standards (*see* Part C 'Structural Design/ Section 1 Loads and Load effects' of this NBCS) for dead, imposed, wind, snow loads, etc, and also for seismic loads that the structure is subjected to during its lifetime.

3.18 Partial Safety Factor for Loads — The factors multiplied by the loads or their combinations to obtain design loads while checking performance under various limit states.

3.19 m-k Factors — Physically, in a composite slab, 'm' is a broad measure of the mechanical interlock between the embossed profiled decking sheet and the reinforced cement concrete on top of the deck, and 'k' represents the frictional resistance between the two elements that is, steel and concrete (*see* Fig. 38).

3.20 Rigid Shear Connectors — These are shear hoops welded to bars, angles, horseshoes or tees welded to the flange of the fabricated steel units, as shown in Fig. 8(b) and Fig. 8 (c). They resist shear forces by concrete bearing on the vertical face and shearing. They exhibit negligible deformation under shear transfer (that is, brittle failure). These are not usually recommended for ultimate limit state design.

3.21 Service Limit — The loading state beyond which the structure or its components becomes incapable of performing its intended function due to excessive deformation, or deflection, or vibration.

3.22 Serviceability Loads — The loads on the structure against which the serviceability of the structure needs to be checked.

3.23 Shear Connectors — These are the mechanical attachments to steel members to transfer interface shear between steel and concrete to develop composite action and are composed of flexible shear connectors [Fig. 8 (a), Fig. 8 (c)], rigid shear connectors [Fig. 8 (b)], etc.

3.24 S-N Curve — Curve, defining the relationship between the numbers of stress cycles to failure Nsc at a constant stress range Sc, during fatigue loading on parts of a structure.

3.25 Strength Factors — The factors by which the specified strength is divided to obtain design strength; while assessing the safety under limit states of strength.

3.26 Stress Range — Algebraic difference between two extremes of stresses in a cycle of loading at a location in a member.

3.27 Superimposed Dead Load — The dead loads added subsequent to concrete hardening of concrete that is resisted by composite action.

3.28 Transient Load — The loads that are assumed to be varying over a short time interval like imposed load, loads with dynamic effect, temperature effects, wind loads on the structure, earthquake loads, accident loads, etc.

3.29 Ultimate Limit State — The state at which the structure fails and loses its integrity leading to its collapse.

4 SYMBOLS

For the purpose of this Subsection, the symbols (other than those used for load categorization) given in Annex A are applicable.

5 MATERIALS AND WORKMANSHIP

5.1 The main materials for composite construction are structural steel, reinforcing steel, and concrete. The materials and workmanship of structural steel shall generally comply with specifications laid down in as per good practice [C-6B(3)], and that of reinforced concrete shall comply with specifications laid down in as per good practice [C-6B(2)]. However, the general properties and specifications of materials for composite construction are detailed as given in **5.2** to **5.4**.

5.2 Structural Steel

All the structural steel used in general construction, coming under the purview of this NBCS, shall before fabrication conform to the accepted standard [C-6B(4)].

Structural steel other than those complying with the accepted standard [C-6B(4)] may also be used provided that the limiting stresses and other design provisions are suitably modified and the steel is also suitable for the type of fabrication adopted.

Steel that is not supported by mill test results may be used only in unimportant members and details, where their properties such as ductility and weldability would not affect the performance requirements of the members and the structure as a whole. However, such steels may be used in the structural system after confirming their quality is as per the accepted standard [C-6B(4)], by carrying out appropriate tests in accordance with the method specified in the accepted standard [C-6B(5)].

5.2.1 *Properties of Structural Steel*

The following physical properties shall be assumed for all grades of steel for design purposes:

Unit mass of steel = 7 850 kg/m^3

Young's modulus (modulus of elasticity) = 2.0×10^5 MPa

Shear modulus = 0.769×10^5 MPa

Poisson's ratio = 0.30

Coefficient of thermal expansion = 0.000 012/°C

The mechanical properties of steel like yield stress, ultimate stress and, elongation shall be as per values indicated in as per good practice [C-6B(3)].

5.2.2 *Specifications of Structural Steel*

Unless otherwise permitted herein, structural steel used shall, before fabrication, comply with the requirements of the accepted standards [C-6B(6)].

The use of structural steel not covered by the above standards may be permitted with the specific approval of the competent authority.

5.2.3 *Other Steels*

Except where permitted with the specific approval of the authority, steels for machined parts and for uses in features other than structural members or elements shall comply with the relevant accepted standards [C-6B(7)], as appropriate.

5.2.4 *Castings and Forgings*

Steel casting and forgings shall comply with the requirements of the Indian Standards the accepted standard [C-6B(8)] as appropriate.

5.2.5 *Fasteners*

Bolts, nuts, washers and rivets shall comply with the following or relevant accepted standard [C-6B(9)], as appropriate.

5.2.6 *Welding Consumables and Practices*

Welding consumables and practices shall comply with the following accepted standard [C-6B(10)], as appropriate.

5.2.7 *Wire Ropes and Cables*

These shall conform to the relevant accepted standard [C-6B(11)] except where the use of other types is specifically permitted by the authority.

5.3 Concrete

5.3.1 All structural reinforced concrete shall be of minimum grade M20 and shall be in accordance with material specification and workmanship as stipulated in as per good practice [C-6B(2)]. The strengths shall be specified in terms of the characteristic compressive strengths of cubes, f_{ck}, measured at 28 days. The design provisions in this Subsection are applicable for concrete strength between M20 to M75. Specialist literature shall be adopted in composite design, while using concrete strength outside this range.

5.3.2 Concrete grade shall be designated based on its characteristic strength. The three main categories of concrete strength grade are given below, and the recommended design properties of concrete are correlated to 28 day characteristic compressive strength unless specified otherwise. The mechanical properties of concrete, namely, tensile strength and modulus of elasticity, shall be determined as per good practice [C-6B(2)]. Additional data is given in Annex F.

a) *Ordinary Concrete* — Concrete grades up to M20 are included in this type. It could be prepared by a nominal mix proportioned by the weight of its main ingredients;

b) *Standard Concrete* — This type comprises of concrete grades from M25 to M55. It is made based on a design mix proportioned by the weight of its main ingredients, along with chemical admixtures to achieve certain target values; and

c) *High Strength Concrete* — Concrete grades from M60 to M80 are included in this type. Even though usage of high strength concrete is allowed in composite construction, capacity equations specified in this provision shall not be directly used in the design. Specialist literature and experimental results are required for using this concrete.

5.3.3 *Lightweight Concrete*

Lightweight concrete may be used in composite construction, and the design provisions in this NBCS shall be used within a strength range of M20 to M60. The mean tensile strength $f_{ctm,l}$ and modulus of elasticity $E_{cm,l}$ of lightweight concrete is to be calculated as modifications over the provisions in [C-6B(2)], as follows:

$$f_{\mathrm{ctm,l}} = \eta_{\mathrm{l}} f_{\mathrm{ctm}}$$

$$E_{\mathrm{cm,l}} = \eta_{\mathrm{E}} E_{\mathrm{cm}}$$

The factors η_{l} and η_{E} are determined using the following equation:

$$\eta_{\mathrm{l}} = 0.4 + \frac{0.6\,\rho}{2\,200}$$

$$\eta_{\mathrm{E}} = \left(\frac{\rho}{2\,200}\right)^2$$

Here, ρ is the upper limit of the oven-dry density of the relevant class of lightweight concrete, as given in Table 1.

Table 1 Density Classes and Corresponding Design Densities for Lightweight Concrete

(*Clause* 5.3.3)

Sl No.	**Density Class, ρ**		**1.0**	**1.2**	**1.4**	**1.6**	**1.8**	**2.0**
(1)	(2)		(3)	(4)	(5)	(6)	(7)	(8)
i)	Density range (kg/m^3)		801 to 1 000	1 001 to 1 200	1 201 to 1 400	1 401 to 1 600	1 601 to 1 800	1 801 to 2 000
ii)	Density (kg/m^3)	Plain concrete	1 050	1 250	1 450	1 650	1 850	2 050
		Reinforced concrete	1150	1 350	1 550	1 750	1 950	2 150

5.3.4 Design of concrete components of a composite structure against creep, shrinkage and temperature stress may be done as indicated in as per good practice [C-6B(2)] or as per specialist literature.

5.4 Reinforcement Steel

5.4.1 Reinforcement steel shall consist of hot rolled, thermo-mechanically treated, or heat-treated rods, de-coiled rods, or cold-worked steel of various grades as given in Table 2. The grade designations and strength properties are given in Table 3.

Table 2 Grades of Reinforcing Steel

(*Clause* 5.4.1)

Sl No.	**Types of Steel**	**Grade/Designation**	**Relevant Standard**
(1)	(2)	(3)	(4)
i)	Mild steel (MS)	Grade I	[C-6B(12)]
ii)	High yield strength deformed (HYSD)	Fe 415, Fe 415S, Fe 415D Fe 500, Fe 500S, Fe 500D, Fe 550, Fe 550D, Fe 600	[C-6B(13)]

5.4.2 The minimum strength of reinforcing steel as specified in as per good practice [C-6B(2)] is either the yield stress in case of mild steel or 0.2 percent proof strength in case of high yield strength steel and it is notionally taken as the characteristic strength of reinforcement f_{yk} .

5.4.3 The steel may be coated or galvanized to improve its corrosion resistance. The following corrosion resistive steel may be used as reinforcements:

a) *Galvanized Reinforcements* — The strength, elongation and bond properties are not adversely affected by galvanizing;

b) *Epoxy-coated Reinforcements* — These are reinforcements conforming to the accepted standard [C-6B(13)] coated by fusion bonding epoxy conforming to the accepted standard [C-6B(14)]. The bond of coated reinforcements is lowered by up to 20 percent compared to un-coated reinforcements. The lap length and anchorage length shall be increased by 25 percent while using these steel bars; and

Stainless Steel Reinforcements — Properties of stainless steel reinforcement shall not be inferior to carbon steel reinforcement of corresponding strength and class. These are reinforcements conforming to the accepted standard [C-6B(15)].

Table 3 Strength of Reinforcing Steel

(*Clause* 5.4.1)

Sl No.	Type of Steel	Grade/ Designation	Minimum Yield Stress/0.2 Percent Proof Stress,	Minimum Tensile Strength, as Percent of the Actual 0.2 Percent Proof Stress/Yield Stress But Not Less Than	Minimum Percent Elongation
(1)	(2)	(3)	(4)	(5)	(6)
i)	Mild steel	Grade - I	Bars up to and including 20 mm dia = 250 MPa	410 MPa	23.0
			Bar dia > 20 mm ≤ 50 mm = 240 MPa	410 MPa	23.0
ii)	High yield strength deformed steel (HYSD)	Fe 415	415 MPa	110 Percent (≥ 485 MPa)	14.5
		Fe 415D/S		112 Percent (≥ 500 MPa)	18.0
		Fe 500	500 MPa	108 Percent (≥ 545 MPa)	12.0
		Fe 500D/S		110 Percent (≥ 565 MPa)	16.0
		Fe 550	550 MPa	110 Percent (≥ 585 MPa)	10.0
		Fe 550 D		108 Percent (≥ 600 MPa)	14.5
		Fe 600	600 MPa	106 Percent (≥ 600 MPa)	10.0

NOTES

1 Elongation on a gauge length of $5.65\sqrt{A}$, where A is the cross-sectional area of the test piece, when tested in accordance with [C-6B(5)].

2 For Seismic Zone III, IV and V; HYSD steel bars having a minimum elongation of 14.5 percent and conforming to other requirements of [C-6B(13)] shall be used.

3 For Seismic Zone III, IV and V; Structural steel maximum yield strength shall not exceed the specified minimum value by more than 20 percent and conforming to other requirements of [C-6B(13)] shall be used.

6 STRUCTURAL ANALYSIS

This section is applicable to composite structures in which most of the members are composite. Where the structural behaviour is essentially that of reinforced or prestressed concrete, with only a few composite members, analysis provisions of as per good practice [C-6B(2)] or as per good practice [C-6B(16)] respectively, shall be used. Similarly, where the structural behaviour is essentially that of structural steel, with only a few composite members, analysis provisions of as per good practice [C-6B(3)] shall be used.

6.1 Modelling and Basic Assumptions

6.1.1 *Local Buckling of Plate Elements of Steel Section and Section Classification*

The types of elements that are encountered in steel sections are listed below:

a) Internal elements are elements attached along both longitudinal edges to other elements or to longitudinal stiffeners connected at suitable intervals to transverse stiffeners, for example, web of I-section and flanges and web of box section;

b) Outside elements or outstands are elements attached along only one of the longitudinal edges to an adjacent element, the other edge being free to displace out of plane for example, flange overhang of an I-section, the stem of T-section and legs of an angle section; and

c) Tapered elements may be treated as a flat elements having an average thickness as defined in the accepted standard [C-6B(17)].

6.1.2 The section strength at the ultimate limit state should be considered based on their ability to resist local buckling before full plastic strength is developed. In this respect, the structural steel sections may be classified as given in as per good practice [C-6B(3)]. Guidelines for sectional classification of composite sections with and without concrete encasements are given below:

a) *Composite Sections*

1) Steel compression elements (plates) in a composite section should be classified according to the least favourable class of steel elements in compression;

2) The class of a composite section depends on the direction of the bending moment at that section;

3) A steel compression element restrained by a reinforced concrete element through shear connectors may be placed in a more favourable class, after ensuring its improved local buckling resistance due to the above connection;

4) Plastic stress distribution over the cross section should be used for section classifications 1 and 2. In classification 3, the elastic stress distribution should be used taking into account the sequence of construction and the effects of creep and shrinkage;

5) For classification, design values of the strength of materials should be taken. Concrete in tension should be neglected. The stress distribution should be established for the gross cross-section of the steel web and the effective concrete flanges;

6) The tension capacity of steel reinforcements satisfying the ductility requirements specified in 5.4, only can be used in evaluating the strength in the hogging moment regions of the composite members. When the design resisting moment of the full or partial composite members is evaluated based on either simple rectangular stress block or parabolic stress block, the minimum area of steel reinforcement, A_{st}, used within the effective width of the concrete flange should satisfy the following:

$$A_{st} = A_c\, \alpha\, \frac{1}{\varepsilon^2}\frac{f_{ctm}}{f_{yk}}\sqrt{k_c}$$

where

ε = $\sqrt{250/f_y}$;

A_c = Effective area of the concrete flange;

f_y = Nominal value of yield strength of structural steel, in MPa;

f_{yk} = Characteristic yield strength of tension reinforcement, in MPa;

f_{ctm} = Mean tensile strength of concrete, in MPa (Annex F);

k_c = $\frac{1}{(1+d_s/(2\,z_0))} + 0.3 \le 1.0$;

α = 1.06 for compact section, 1.17 for plastic section;

d_s = thickness of concrete slab excluding haunch if any; and

z_0 = vertical distance between the centroid of the uncracked concrete slab and the centroid of the uncracked effective composite section using the modular ratio m for short-term loading.

7) The welded mesh should not be included in the effective section unless it has sufficient ductility before fracture when embedded in concrete; and

8) Account should be taken of the class of steel section at every stage of construction in the global elastic analysis.

b) *Composite Sections without Concrete Encasements*

1) A steel compression flange that is restrained from buckling by effective attachment to a concrete flange by shear connectors may be assumed to be in class 1 if the maximum spacing of the connectors is in accordance with **11.6.3**;

2) Other steel flanges and webs in compression in the composite beams should be classified on the basis of width to thickness ratios and susceptibility to local buckling of steel only unless they are also restrained by concrete as in columns. Accordingly, sections are categorized into three groups as indicated in as per good practice [C-6B(3)]; and

3) In beams, cross-sections with webs in Class 3 and flanges in Class 1 or 2 may be treated as an effective cross-section in Class 2 with an effective web in accordance with Fig. 1. The proportion of the web in compression should be replaced by a part of $20\varepsilon t_w$ adjacent to the compression flange, with another part of $20\varepsilon\, tw$ adjacent to the plastic neutral axis of the effective cross-section where ε = $\sqrt{250/f_y}$ and t_w is the thickness of the web.

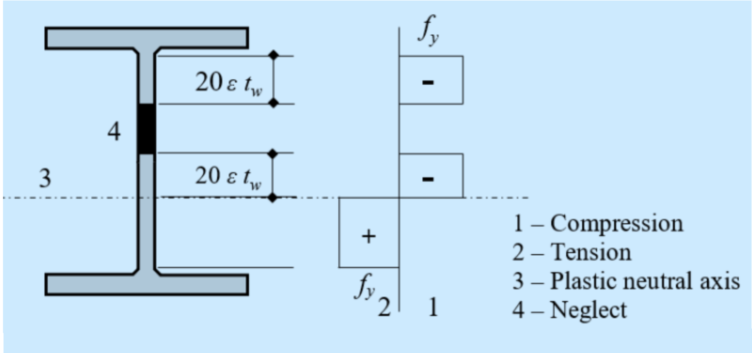

FIG. 1 EFFECTIVE CLASS 2 WEB IN BENDING

c) *Composite section with concrete encasements*

1) A steel outstand flange shall be classified as per Table 4; and

2) In partially concrete-encased I-section (Fig. 2), wherein the concrete is effectively attached to the web with stud or any reinforcement and covers on each side of the at least 80 percent of the flange overhang, the limiting overhang width of the flange to thickness ratio, b/t_f, for section classification may be taken as given in Table 4, where ε = $\sqrt{250/f_y}$.

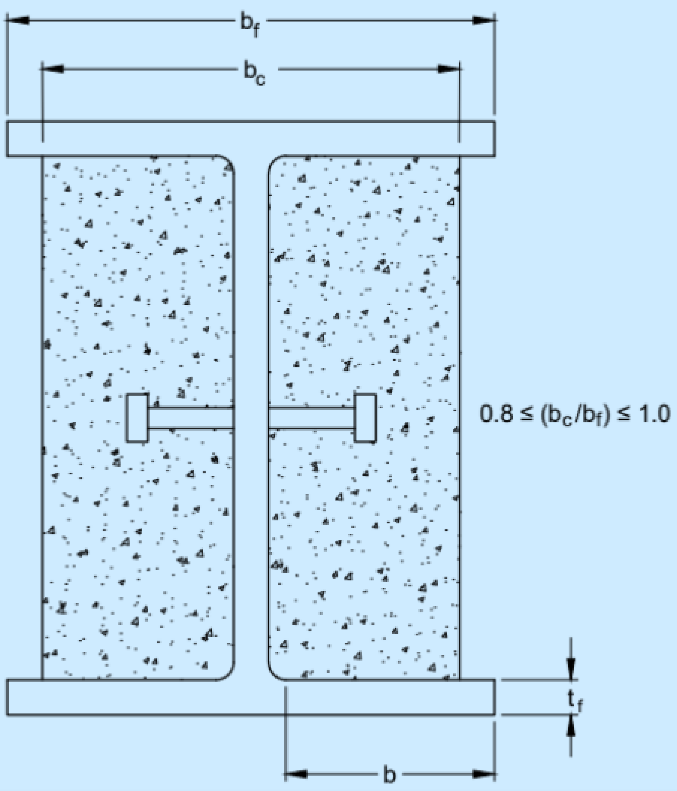

FIG. 2 PARTIALLY ENCASED I-SECTION

Table 4 Encased I Section Classification

[*Clause* 6.1.2(c)]

Sl No.	Section	Flange Overhang to Thickness Ratio (b/t_f)		
		Class 1 Plastic	Class 2 Compact	Class 3 Semi-compact
(1)	(2)	(3)	(4)	(5)
i)	Rolled section	9.4 ε	10.5 ε	15.7 ε
ii)	Welded section	8.4 ε	9.4 ε	13.6 ε

6.1.3 *Joints*

Joints in a composite structure may be modelled as:

a) Hinged, wherein the connection transfers only axial force and shear force, and negligible moment may be assumed to be transferred;

b) Rigid, wherein relative deformation between the members being joined is negligible due to the rigid nature of the joint, and the compatibility of deformation of the adjacent members at the joint may be assumed in the analysis; and

c) Semi-rigid, wherein the joint deformation under the force transferred across the joint should be modelled.

The effects of the deformation behaviour of the joints on the internal force resultants and deformations in the members and structure may be generally neglected. However, where such effects may be significant (such as in semi-rigid connections), they shall be considered as discussed in as per good practice [C-6B(3)].

6.1.4 *Foundation Support*

Normally the support from the foundation may be assumed as hinged or rigid, depending on the soil condition and foundation type. Effects of support deformation may be considered, where significant.

6.1.5 *Deformation of the Structure*

6.1.5.1 If under the external actions, the deformations are small, then the analysis can be done by studying the equilibrium of the undeformed structure. Such an analysis is referred to as first-order analysis or linear elastic analysis.

6.1.5.2 If under the external actions, the deformations are large enough to significantly affect or modify the structural behaviour, then the analysis should be performed considering the equilibrium of the structure under deformed configuration. Such an analysis is referred to as second-order analysis.

6.1.5.3 First-order analysis is adequate if the increase in the internal forces or moments due to actions on the deformation from the first-order analysis is less than 10 percent. This may be assumed to be satisfied if the ratio of the P_{cr}/P_d is greater than or equal to 10, where P_{cr} is the load corresponding to elastic instability of the member or structure as a whole and P_d, is the factored design compressive load. In evaluating the elastic critical load, P_{cr}, effect of cracking and creep of concrete, deformation of the joint shall be considered.

6.1.6 *Imperfections*

Effects of imperfections in the member (local imperfections) and imperfections in the overall geometry of the structure should be considered if they are significant. The first order analysis does not account for these, and hence the design method used should consider these effects. The second-order analysis should include the imperfections in the modelling, if the ratio of elastic critical load to the factored design loads, $P_{cr}/P_d < 4.0$. If the second-order analysis does not include the imperfection effects (when $P_{cr}/P_d \geq 4.0$), the design method used should consider the imperfection effects. If the second-order analysis includes imperfection modelling, then the design method shall not include the effects of imperfections.

6.1.7 *Shear Lag and Effective Width of Flanges*

The effectiveness of steel and concrete flanges is reduced due to shear deformation in their plane either through rigorous analysis or by using effective width of the concrete as given in section **8.3.3** and that of steel flanges as given in as per good practice [C-6B(3)].

6.1.8 *Creep, Shrinkage and Temperature*

The effect of creep of concrete on the internal forces can be accounted by using effective modulus of elasticity of concrete, as recommended in as per good practice [C-6B(2)], by considering the creep and the age of concrete at the time of loading. The shrinkage strain may be taken as recommended in as per good practice [C-6B(2)] or as per specialized literature.

When permanent loads are imposed in several stages, one mean value of time may be used for calculating creep coefficient. Such a mean value may also be used for evaluating prestressing deformations if the age of the relevant portion of the concrete at the time of prestressing is more than 14 days.

If a prefabricated and prestressed concrete slab is made composite with structural steel subsequently, the creep and shrinkage values only after the composite action becomes effective are to be taken.

The effects of creep, shrinkage and differential temperature, in terms of internal forces, moments and deformation in determinate structure and indeterminate structures, where compatibility is not enforced, are referred to as 'primary effects'. In indeterminate structures, wherein the compatibility of deformation is ensured in the analysis, the additional effects of enforcing compatibility are referred to as 'secondary effects'.

The effects of creep, shrinkage, and temperature are normally neglected in analysis for the ultimate limit state other than fatigue for composite members, in which steel sections used should meet either plastic or compact classification.

The characteristic values of indirect actions due to the controlled imposed deformations (for example jacking of supports) may be calculated using the characteristic or nominal values of material properties in prestressed indeterminate composite beams and slabs unless a more accurate method is followed.

6.1.9 *Cracking of Concrete*

The effect of cracking of concrete in tension zones, as obtained from elastic analysis of the uncracked concrete model, may be considered by using effective stiffness of cracked concrete as given in as per good practice [C-6B(2)].

6.1.10 *Sequence of Construction*

Depending upon the type of construction (propped/unpropped, prestressed, precast, etc) the model for different stages of loading may differ. For the resultant internal forces, stresses and deflection at service load considering the effects of the staged construction may be obtained by superposing the analysis results for different loads obtained from different appropriate models for the stage of construction.

The effect of the sequence of construction may be neglected in structures made of plastic and compact steel sections and the model corresponding to the final stage of construction may be utilized for the ultimate limit state, other than fatigue.

6.2 Methods of Global Analysis

Different methods of global analysis, as discussed in the following sections, are permitted. The design and member strength check methods are chosen to be consistent with assumptions in analysis and actual global/member behaviour. Linear elastic first order method is most commonly used, but the second order effects and member imperfection effects, etc. Have to be taken care of in the design and member check stages.

6.2.1 *Linear Elastic Analysis*

6.2.1.1 Effect of cracking of concrete in tension, creep, shrinkage, temperature, prestressing and sequence of construction should be considered in the linear elastic analysis, as discussed in **6.1** and **7**. Forces and moments from the linear elastic analysis may be used even when the design is based on the ultimate limit state. In the case of continuous structures with hogging moments over supports, evaluation of the effective section at supports may be necessary, as mentioned in **8.3.3**. Appropriate load combinations with corresponding load factors are to be used to find out the maximum design values of moments and shears.

The stability of a structure as a whole against overturning shall be ensured under the limit state as per provisions of as per good practice [C-6B(2)]. The foundation components of the structure shall also be safe against sliding under adverse conditions of the applied characteristic loads. The following factor of safety shall be ensured:

a) *Overturning* — The stability of a structure as a whole against overturning shall be ensured so that the restoring moment shall not be less than the sum of 1.2 times the maximum overturning moment due to the characteristic dead load and 1.4 times the maximum overturning moment due to the characteristic imposed loads. In cases where dead load provides the restoring moment, only 0.9 times the characteristic dead load as per good practice [C-6B(2)] shall be considered. Restoring moments due to imposed loads shall be ignored;

b) *Sliding* — The structure shall have a factor against sliding of not less than 1.4 under the most adverse combination of the applied characteristic forces. In this case also, only 0.9 times the characteristic dead load shall be taken into account if it assists in resisting sliding; and

c) *Instability* — Linear elastic instability analysis of member and the global system is possible, wherein first order assumptions and the resulting eigenvalue problem leads to eigenvalues as the instability load,

6.2.1.2 *Redistribution of moments from first order analysis*

Bending moments obtained from the linear elastic analysis of indeterminate slabs, beams and frames in composite structures in buildings may be redistributed to a limited extent as given below while ensuring the equilibrium is still satisfied:

a) concrete members are subjected primarily to flexure in accordance with as per good practice [C-6B(2)];

b) steel members satisfy the plastic section requirements of as per good practice [C-6B(3)];

c) composite members have partial or full shear connection as given in **11**;

d) redistributed internal forces and moments should satisfy equilibrium;

e) inelastic behaviour of the material, and local and lateral-torsional buckling should allow such a redistribution;

f) at least one end of the beam should be connected by a rigid or full-strength joint to the adjacent member; and

g) each span is of uniform depth.

Table 5 gives the maximum percentage reduction in the hogging bending moments obtained from linear elastic global analysis, in composite beams, unless it is verified that the plastic rotation capacity permits a higher value.

Table 5 Limits to Percentage Redistribution of Hogging Bending Moments Obtained from Linear Elastic Analysis

(*Clause* 6.2.1.2)

Sl No. (1)	Classification of the Cross-Section in the Hogging Moment Region (2)	Plastic (3)	Compact (4)	Semi-compact (5)	Slender (6)
i)	For un-cracked section analysis moment	40	30	20	10
ii)	For cracked section analysis moment	25	15	10	0

NOTES

1 For grades of steel having yield strength greater than 360 MPa, redistribution is applicable to beams with plastic or compact cross-sections. In the redistribution, the reduction in hogging moment should not exceed the values for compact sections given in Table 5, unless it is demonstrated that rotation capacity permits a higher value.

2 The limits in Table 5 for semi-compact and slender sections relate to bending moments to be resisted by composite members and moments to be resisted by bare steel section should not be redistributed.

6.2.2 *Non-linear Global Analysis*

The non-linear analysis may be performed as specified in as per good practice [C-6B(3)]. The non-linear behaviour of the shear connection shall be taken into account. Effects of deformed geometry of the structure, imperfections, joint and foundations, creep, shrinkage, temperature, stages of loading shall be taken into account as discussed in **6.1**.

6.2.3 *Rigid Plastic Analysis*

Rigid plastic global analysis may be used in composite structures to obtain ultimate limit state design values other than fatigue if the conditions given below are satisfied. Second-order effects, imperfections, creep, shrinkage, temperature effects, etc. need not be considered in the rigid plastic analysis. The effect of alternating plasticity due to variable loading need not be normally considered in buildings:

a) All the members and joints of the frame are either composite or structural steel;

b) Material and cross-section should satisfy requirements of plastic analysis as given in [C-6B(3)];

c) Joints are able to sustain the plastic resisting moments over a large plastic hinge rotation;

d) Critical plastic hinge location shall satisfy the following requirements:

   1) Cross-section of the structural steel section shall be symmetric about the plane of bending;
   2) restraints are provided to prevent lateral torsional buckling;
   3) lateral restraint is provided to the compression flange at all critical plastic hinge sections under any loading;
   4) The rotation capacity of the section, considering any axial compression at the section, should be adequate to permit the plastic hinge rotation to form the plastic collapse mechanism; and
   5) When rotation requirements are not calculated and ensured, all effective sections at potential plastic hinge locations should be of plastic classification;

e) The plastic hinge rotation capacity in composite sections may be assumed to be adequate where:

   1) the yield strength of structural steel does not exceed 450 MPa;
   2) the concrete slab is of normal density concrete, having a characteristic strength within the range of 25 MPa to 50 MPa;
   3) contribution of reinforced concrete encasement in compression is neglected in calculating design moment resistance;
   4) all effective steel sections at potential plastic hinge rotation should be plastic, and all the other sections should be plastic or compact;
   5) all beam connections to adjacent beams/columns should have adequate plastic rotation capacity or should have a design resisting moment of at least 1.2 times the design plastic resistance of the adjacent beam;
   6) structural steel compression flange at plastic hinge location should be laterally restrained;
   7) adjacent span lengths do not differ by more than 50 percent of the shorter span length;
   8) the end span length is not more than 115 percent of the adjacent span length;
   9) at plastic sections with the concrete slab is under compression, not more than 15 percent of the total depth of the section shall be under compression at the ultimate moment unless the plastic hinge at the section is the last to form (not requiring much plastic hinge rotation);
   10) plastic hinges shall not be located in composite columns unless plastic rotation capacity can be verified;
   11) the lateral support to the compression flange shall be located within half the depth of the steel section from the plastic hinge section; and
   12) sections away from plastic hinge regions should satisfy at least compact section requirements.

7 LIMIT STATE DESIGN

7.1 General

In the limit state design method, the structure shall be designed to withstand safely all loads likely to act on it throughout its life. The objective of the design is to arrive at a structure that will remain fit for use during its life with acceptable target reliability. In other words, the probability of a limit state being reached during its lifetime should be very low. The acceptable limit for the safety and serviceability requirements before failure occurs is called a limit state. In general, the structure shall be designed on the basis of the most critical limit state and shall be checked for other limit states.

For satisfactory functioning of a structure during its design life conditions, stipulations and directives laid down in [C-6B(1)] shall be adequately satisfied for all steel-concrete composite structures.

7.1.1 *Effect of Construction Sequence*

The linear elastic method is valid for the analysis of the structure after considering load history, sequence of concrete casting and development of composite strength. In the case of propped construction, most of the initial dead load is resisted through the beam-prop system and the steel beam remains basically unstressed at this stage. In the case of un-propped construction, the steel beams alone have to carry the initial dead load and construction loads. Consequently, stresses and deflections at this stage shall not exceed specified design limits. The necessary distinction has to be made in the analysis about the stage of loading and the effectiveness of the system resisting the load. In the ultimate limit state, however, this distinction is not necessary while checking for flexural resistance. For the design of steel components and concrete deck, stipulations of as per good practice [C-6B(1)] and this Subsection shall be applied.

7.1.2 The sequence of construction should be considered as an integral part of the design process, for example, when calculating the stresses under serviceability limit criteria. The sequence and method of construction need to be mentioned in the drawings. Additional information such as the position of construction joints, if any, may also be included in the drawings.

Where the composite section is loaded before the concrete has attained its 28 days characteristic cube strength, the elastic properties and limiting compressive strength of the concrete, and the nominal strengths of shear connectors should be based upon the cube strength of the concrete at the time of loading. Where a partially cast slab is assumed to act compositely, the shear connection should be designed for this condition as well as for the final condition. In calculating deflections, consideration should be given to the sequence of construction and, where appropriate, proper account should be taken of the pre-camber of steel section, the deflections of the steel section due to loads applied to it prior to the development of composite action and of partial composite action where deck slabs are cast in stages. In execution, the rate and sequence of concreting should be required to be such that partly matured concrete is not damaged as a result of limited composite action occurring from the deformation of the steel beams under subsequent concreting operations.

7.2 Limit States

A composite structure or part of it is considered unfit for use when it exceeds a particular state called the limit state, beyond which it infringes on one of the criteria governing its performance or use. The limit states can be classified into the following categories:

a) Ultimate limit state;
b) Serviceability limit state; and
c) Fatigue limit state.

7.2.1 *Ultimate Limit State*

It is the state when under the worst combination of factored loads the structure or its components either reach design strength or becomes unstable. Both stability and strength need to be checked under the ultimate limit state.

In steel-concrete composite structures used in buildings or general constructions, the significant ultimate limit states to be considered are as follows:

a) Collapse due to flexural, shear or bearing failure of one or more critical sections or components;
b) Collapse due to horizontal shear failure at the interface between the steel beam and the concrete slab or composite slab system involving concrete slab and embossed profiled sheets;
c) Collapse due to the vertical separation of the concrete/composite slab from the steel beams; and
d) Collapse due to shear failure between steel and concrete components of the composite column or due to buckling of both fully/partially concrete encased steel columns or concrete filled hollow sections used as columns.

7.2.2 *Serviceability Limit States*

It is the state at which any of the following conditions occur during the loads encountered under construction and service:

a) Stress in structural steel has reached the prescribed limit;

b) Stress in concrete has reached the prescribed limit;

c) Deflection of a structure or its component reaches the prescribed limit;

d) Concrete crack width reaches the prescribed limit;

e) Slip at the interface between steel and concrete exceeds the prescribed limit;

f) Vibration becomes excessive, especially at overhangs;

g) Excessive corrosion affecting the durability of the structure; and

h) Unacceptable effects due to fire.

7.2.3 *Fatigue Limit State*

It is the state at which stress range due to the application of imposed loads reaches the prescribed limit, corresponding to the number of load cycles and detail configuration.

7.3 Design Philosophy

For ensuring the design objectives, the design should be based on the characteristic values for material strengths (resistance) and applied loads (actions), which take into account the probability of variations in the material strengths and in the loads to be supported. The characteristic values should be based on statistical data, if available. Where such data is not available, they should be based on experiments. The design values are derived from the characteristic values through the use of partial safety factors, both for material strengths and for loads. In the absence of special considerations, these factors should have the values given in this section according to the material, the type of load and the limit state being considered. The reliability of the design is achieved by ensuring that:

$$\text{Design Action (Load)} \leq \text{Design Strength (Resistance)}$$

Design action refers to the external actions or load which act on the structure and the design resistance refers to the maximum resistance the structure and its components provides to resist the actions without causing failure of the structure and its components or causing hindrances to the smooth operation of the structure for which it is intended.

7.4 Design Actions (Loads)

7.4.1 *Actions* (*Loads*) *are Classified into Three Main Categories*:

a) *Permanent or dead loads* — Loads due to self-weight of structural and non-structural components, fittings, ancillaries, and fixed equipment etc. Dead loads shall be calculated on the basis of unit weights which shall be established taking into consideration the materials specified for construction. Alternatively, the dead loads may be calculated on the basis of nominal dimensions and unit weights of materials given in (*see* Part C 'Structural Design/Section 1 Loads and Load effects' of this NBCS);

b) *Variable or imposed loads* — Construction and service stage loads such as imposed loads (for example, crane loads, impact, etc.), wind loads, snow loads and other loads shall be assumed in accordance with (*see* Part C 'Structural Design/Section 1 Loads and Load effects' of this NBCS) and the earthquake forces shall be calculated in accordance with the same; and

c) *Accidental loads* — Accidental loads are actions or loads expected due to explosions and the impact of vehicles, etc. The characteristic values of accidental loads generally correspond to the value specified by relevant code, standard or client. Design for the accidental load is generally not required in every building unless it is required by the client or approving authority, in which case, general recommendations given in as per good practice [C-6B(3)] or specialist literature shall be followed.

7.4.2 Other than the actions due to the externally applied loads as given in **7.4.1**, if the effects of shrinkage, creep and temperature are liable to affect material safety and serviceability of the structure, these shall be accounted for in the design calculations (*see* Part C 'Structural Design/Section 1 Loads and Load effects' of this NBCS) .

7.4.3 *Load Combination*

The different combinations of loads considered shall be as given in (*see* Part C 'Structural Design/Section 1 Loads and Load effects' of this NBCS). For each combination, different partial safety factors for loads are assigned to different loads, γ_f to account for:

a) Possibility of unfavourable deviation of the load from the characteristic value;

b) Possibility of inaccurate assessment of the load;

c) Uncertainty in the assessment of effects of the load; and

d) Uncertainty in the assessment of the limit states being considered.

The loads or load effects shall be multiplied by the relevant γ_f factors, given in Table 6, to calculate the design loads or design load effects.

Table 6 Partial Safety Factor for Loads, γ_f for Limit States

(*Clause* 7.4.3 *and* 9.3.2.1)

Sl No.	**Combination**	**Limit State of Strength**					**Limit State of Serviceability**

[1] This value is to be considered when the dead load contribution to stability against overturning is critical or the dead load causes a reduction in stress due to other loads.

[2] When the action of different imposed loads is simultaneously considered, the leading imposed load shall be considered to be the one causing the higher load effects in the member/section.

NOTE — The effects of actions (loads) in terms of stresses or stress resultants may be obtained from an appropriate method of analysis.

Abbreviations: DL= Dead Load, LL= Imposed Load, WL= Wind Load, CL= Crane Load (Vertical / horizontal), AL=Accidental Load, ER= Erection Load, EL= Earthquake Load.

7.5 Material Strength and Partial Safety Factor

The design strength, S_d of a structural component, is obtained as given below from nominal ultimate strength, S_u, and partial safety factors for material strength, γ_m.

$$S_d = S_u/\gamma_m$$

where the partial safety factor for materials, γ_m, (*see* Table 7), account for:

a) Possibility of unfavorable deviation of material strength from the characteristic value;

---

[1] This value is to be considered when the dead load contribution to stability against overturning is critical or the dead load causes a reduction in stress due to other loads.

[2] When the action of different imposed loads is simultaneously considered, the leading imposed load shall be considered to be the one causing the higher load effects in the member/section.

b) Possibility of unfavorable variation of member sizes;

c) Possibility of unfavorable reduction in member strength due to fabrication and tolerances; and

d) Uncertainty in the calculation of the strength of the members.

Table 7 Partial Safety Factor for Material γ_m

(*Clauses* 7.5, 8.3.5.1, 8.3.6.1 *and* 9.1.2)

Sl No. (1)	Material (2)	Item (3)	Partial Safety Factor γ_m (4)
i)	Structural steel, and steel sheeting	Resistance against yield stress, γ_{m0}	1.10
		Resistance of member to buckling, γ_{m0}	1.10
		Resistance against ultimate stress γ_{m1}	1.25
ii)	Reinforcement	Reinforcement resistance against yield stress,γ_k	1.15
iii)	Shear connectors	Yield stress, γ_{mv}	1.25
iv)	Connections	Bolts-friction type, γ_{mf}	1.25

		Rivets, γ_{mr}	1.25
		Welds for shop fabrication, γ_{mw}	1.25
		Welds for site fabrication, γ_{mw}	1.50
v)	Concrete	For basic and seismic load combinations, γ_c	1.50

NOTE — The partial safety factor for resistance for all materials in case of accidental loads = 1.0

8 DESIGN FOR ULTIMATE LIMIT STATES

8.1 Composite Beams

Composite beams shall be checked for the following:

a) resistance to flexure;

b) resistance to lateral-torsional buckling;

c) resistance to web shear buckling;

d) resistance to longitudinal shear (between steel and concrete components).

8.1.1 *Assumptions*

Design for the limit state of collapse in flexure shall be based on the assumptions given below:

a) Plane sections normal to the neutral axis remain plane and normal after bending;

b) The maximum strain in concrete at the outermost compression fiber at collapse is taken as 0.003 5 in bending as per good practice [C-6B(2)];

c) The tensile strength of the concrete is ignored;

d) The stress-strain curve for the reinforcing steel shall be assumed to be the same as given in as per good practice [C-6B(2)];

e) The properties of structural steel shall be taken as given in as per good practice [C-6B(3)]; and

f) The stress-strain curve for concrete may be taken to be the same as given in as per good practice [C-6B(2)]. The corresponding parabolic stress block may be used to evaluate the design bending resistance of composite beams and slabs. The bending resistance of a composite beam for the value of concrete stress using an equivalent rectangular stress block, which simplifies the design resistance equation, may be used as an alternative method. Both methods and the design resistance equations are given in Annex B.

NOTE — Critical cross-sections include the following:

a) the sections where the bending moment is maximum;
b) the section at the faces of the support;
c) sections adjacent to concentrated force or reactions; and
d) locations where a sudden change of cross-section occurs; (ratio of greater to the lesser resisting moment at adjacent sections exceeds 1.2) (changes due to cracking of concrete not to be included).

8.1.2 *Ultimate Bending Resistance*

For determining the position of the plastic neutral axis and the ultimate moment of resistance of composite beams, the guidelines given in Annex B may be used.

8.1.2.1 *General*

Composite constructions of types: (a) Top flange of steel beam supporting the concrete slab (Fig. 3) and (b) composite slab resting on structural steel beam (Fig. 4) are included in this design philosophy. A typical composite beam arrangement is shown in Fig. 3, where cast in place or precast RC slab is directly resting on the steel beam. Fig. 4 depict a composite slab consisting of RC and profiled deck sheet with or without embossments) and supported on a structural steel beam, parallel and perpendicular to the steel beam, respectively. The neutral axis may be in the concrete slab, in the top flange of the steel section, or in the web of the steel section.

Fig. 4 Typical Composite Beams with Profiled Decking Sheet (a) Ribs Parallel to Beams (b) Ribs Perpendicular to Beam

Bending moments and shears due to the application of factored loads may be analyzed in indeterminate structures by elastic theory assuming the concrete in the slab as un-cracked and unreinforced.

Hogging moments over internal supports as calculated above should be checked against section resistance assuming steel beam acting integrally with concrete (considering un-cracked and unreinforced). If the flexural tensile stress in concrete thus calculated exceeds the tensile strength of concrete, $f_{ctk,\,0.05}$ as in Annex F then a new analysis, neglecting concrete but including reinforcements over the effective width of the slab (*see* **8.3.3**) and over 15 percent of the span on each side of the support should be done to calculate the required design resistance, provided adjacent spans do not differ appreciably.

The redistribution of elastic analysis moment of indeterminate structure, as recommended in **6.2.1.2**, is allowed to arrive at the design moments in the case of plastic beams. Design for plastic analysis moments (as given in **6.2.3**) is permitted in the case of beams classified as plastic.

The bottom flange of the beam in the hogging moment zone should be adequately braced against lateral buckling. Otherwise, lateral buckling resistance has to be evaluated as recommended in **B-4**.

8.2 Precast Slab on Steel Beam

The use of precast slab, both full depth and partial depth, is allowed for composite construction as one of the components of composite beams. Precast slabs shall be erected and connected to the steel section so as to ensure composite action along with the steel beam.

8.2.1 *Full Depth Precast Slab*

Full-depth precast concrete deck panels may be used for new construction as well as for the replacement of deteriorated concrete decks on existing steel beams so as to obtain composite action. This shall be ensured by proper shear connection during the erection of these precast panels. The typical requirements for these types of beams are as given below:

a) Panels shall either span the full width of the concreting deck or shall be in lengths that span between two or more parallel beams. The minimum thickness of the slab shall be 150 mm;

b) The panels shall be connected to the beams using shear connectors in pockets, which consist of mechanical connectors, such as shear studs encapsulated in non-shrinking grouted pockets. These connections cause the panels to develop composite action with the beams; and

c) The contact between the precas t panels at their longitudinal edge should ensure transfer of compression between the panels, necessary for composite action.

8.2.2 *Partial Depth Precast Slab*

Partial depth precast concrete deck panels are generally thin RCC/prestressed concrete panels that span between beams and also serve as forms/shuttering for the cast-in-place concrete deck. The typical geometrical parameters that govern the use of these panels as a composite unit for the floor system are as given below:

a) The minimum thickness of the precast panels shall be 75 mm;

b) As a composite floor system, the cast in-situ concrete and the partial-depth panels together create the total thickness of the slab, with the panel reinforcing steel serving as the positive moment reinforcement in the bending direction of the combined slab;

c) Dimensions of the precast panels shall be chosen from consideration of easy handling, ease of lifting by cranes and for catering to the construction loads, including load of wet cast in-situ concrete;

d) Partial-depth panels must be capable of developing sufficient composite action with the cast *in-situ* concrete to be an effective floor system;

e) To ensure full bond between the cast *in-situ* concrete and precast panels, it is recommended that the top surface of the precast panel is intentionally roughened while casting it and is cleaned by removing the laitance or other contaminants on the surface and other measures may be taken, before the placement of the cast *in-situ* concrete so as to ensure a good bond between precast and cast in place concrete; and

f) After the precast panels are in place, the top layer of the reinforcing steel shall be placed over it, and the cast-in-situ concrete shall be placed on top of the panels.

8.2.3 *General Design Principles*

The design of precast slabs is based on the following principles:

a) The precast slab together with any *in-situ* concrete (for partial depth slab) should be designed as continuous in both the longitudinal and the transverse direction;

b) The joints between slabs should be designed to transmit membrane forces as well as bending moment and shear forces;

c) The effective width of precast slab in the composite beam action shall be calculated as per **8.3.3**;

d) The design principles of composite beams involving either full depth or partial depth precast slabs are similar to standard composite decks using cast *in-situ* reinforced concrete;

e) Vertical shear check of the composite beam shall be done as per **8.3.6**; and

f) For serviceability limit states, guidelines given in **7.2.2** and **9** shall be followed.

8.2.4 *Joints between Steel Beam and Precast Concrete Slab*

a) Where precast slabs are supported on steel beams without bedding, the influence of the vertical tolerances of the bearing surfaces shall be considered; and

b) The shear transfer between steel flange and precast concrete through mechanical shear connector shall be designed as per **11** with the following precautions:

    1) If shear connectors are welded to the steel beam projecting into the recesses within the slabs or joints between slabs, which are filled with concrete after erection, the detailing and the properties of the concrete should be such that it can be cast properly.

    2) The minimum infill around the shear connectors should be at least 25 mm.

    3) If shear connectors are arranged in groups, sufficient reinforcement should be provided near each group to prevent premature local failure in either the precast or the *in-situ* concrete.

    4) Special provision for protection against corrosion shall be adopted, wherein the steel flange under

precast slabs without bedding should have the same corrosion protection as the rest of the steelwork in addition to the top coating provided after erection.

5) Bedding with the purpose of protecting against corrosion may be designed to be non-load bearing.

8.2.5 *Joints between Precast members*

The critical sections of members close to joints should be designed to resist the most adverse combination of shear, axial force and bending caused by the ultimate vertical and horizontal forces. When the design of the precast members is based on the assumption that the joint between them is not capable of transmitting bending moment (*see* **8.3.4**), suitable precautions should be taken to ensure that if any crack developed is not excessive, and reduce the shear or axial force resistance of the member and should not be aesthetically or functionally objectionable.

Where space is left between two or more precast units, to be filled later with *in-situ* concrete or non-shrink grout, the gap should be large enough for easy placement and adequate compaction of the filling material to fill the gap completely.

8.2.6 *Structural Connection at Joints*

When designing and detailing the connections across joints between precast members, the overall stability of the structure, including its stability during construction, shall be considered. A typical joint connection is shown in Fig. 5.

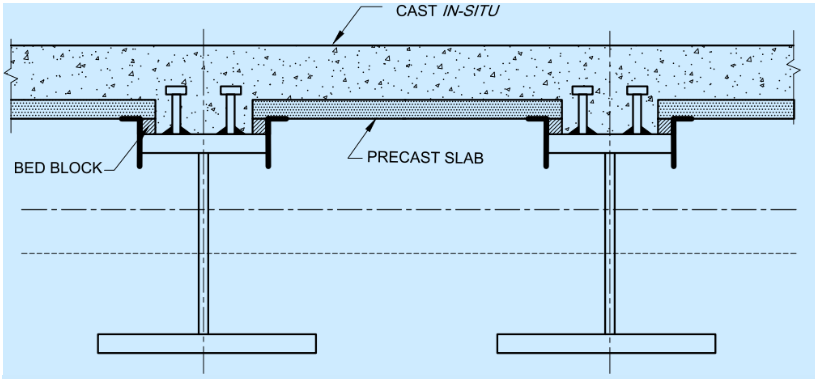

FIG. 5 TYPICAL JOINT CONNECTION FOR PARTIAL DEPTH PRECAST SLAB

8.3 Design Method

Connections should, where possible, be designed in accordance with the generally accepted methods applicable to reinforced concrete or structural steel.

8.3.1 *General Considerations in Design Details*

In addition to ultimate resistance requirements, the following should be considered:

a) *Protection* — Connections should be designed so that the standard of protection against weather and corrosion required for the rest of the structure is sufficiently maintained;

b) *Appearance* — Where connections are to be exposed, they should be designed to achieve and maintain the quality of appearance required for the rest of the structure; and

c) *Manufacture, assembly, and erection* — Methods of manufacture and erection should be considered during design. Care should be taken during erection and the following precautions are mandatory:

   1) Where projecting bars or sections are required, they should be kept to a minimum and made as simple as possible. The lengths of such projections should be not more than necessary;

   2) Fixing devices should be located in concrete sections of adequate strength;

   3) The practicability of both casting and assembly should be considered; and

4) Most connections require the introduction of suitable jointing material. Sufficient space should be allowed in the design for such material to ensure that the proper filling of the joint is possible.

8.3.2 *Reinforcement Continuity at Joint*

Where continuity of reinforcement is required through the connection, the joining method used should be such that the assumptions made in analyzing the structure and critical sections are realized. The standard methods applicable for achieving continuity of reinforcements are lapping, butt welding of bars and grout couplers.

8.3.3 *Effective Width of Concrete Slab*

a) For resistance calculation, the width of the slab, which is effective as the compression flange of the composite beam on each side of the steel beam, b_{eff}, shall be as per the equation given below:

$$b_{\text{eff}} = b_{\text{o}} + (b_{\text{e1}} + b_{\text{e2}}) = b_{\text{o}} + \frac{L_{\text{e}}}{4} \leq b_{\text{o}} + (b_1 + b_2)$$

where

b_{o} = centre to centre between the outer row of shear connectors;

$b_{\text{e1}}, b_{\text{e2}}$ = are the value of the effective width of the concrete flange on each side of the web and taken as $L_{\text{e}}/8$ but not greater than the geometric width b_1 and b_2, respectively as shown in Fig. 6;

$L_{\text{e}}/8 \leq b_1$ and b_2 (*respectively*);

L_{e} = the effective equivalent span length of the corresponding composite beam;

centre-to-centre distance between the supports for simply supported beam; and

as shown in Fig. 7 in a continuously supported beam.

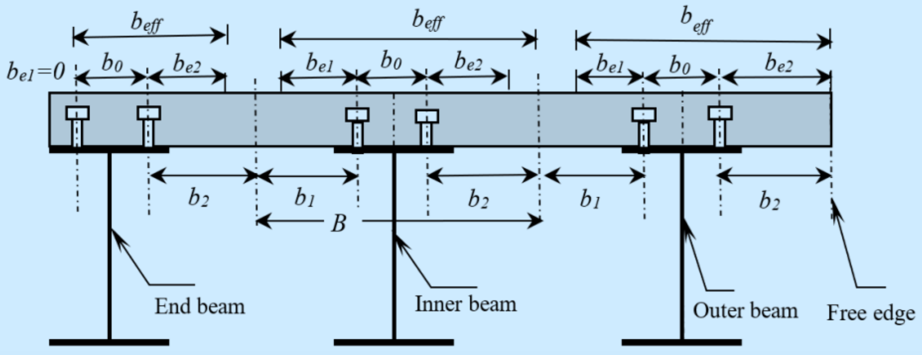

FIG. 6 EFFECTIVE WIDTHS FOR CONCRETE FLANGE OF COMPOSITE BEAMS

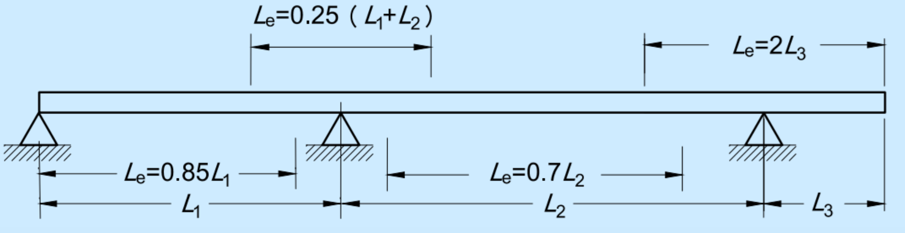

FIG. 7 EQUIVALENT SPANS FOR BEAM CONTINUITY

Reinforcements placed parallel to the steel beam within the effective width of the concrete slab should be considered for hogging moment resistance calculation of the composite beam at the continuous support.

b) The effective width at an end beam may be determined as:

$$b_{\text{eff}} = b_0 + \beta_{e1}\, b_{\text{e1}} + \beta_{e2}\, b_{\text{e2}}$$

where

β_{e1} = $0.55 + 0.025\,(L_{\text{e}}/b_{\text{e1}}) \leq 1.0$

β_{e2} = $0.55 + 0.025\,(L_{\text{e}}/b_{\text{e2}}) \leq 1.0$

L_{e} = Equivalent effective end span; and

b_{e1} = 0 as shown in Fig. 6.

8.3.4 *Effective Cross Section for Strength Calculation*

In calculating the strength of the cross section of the composite beams, the following should be considered:

a) For Sagging Moment — Concrete in the effective width and structural steel beam to be included but not the steel reinforcements in the effective width of concrete; and

b) For Hogging Moment — Concrete to be neglected but longitudinal steel reinforcement along the beam length within the effective width of the concrete in tension and structural steel beam to be included.

8.3.5 *Design of Structure for Bending Moment*

8.3.5.1 The factored design flexural strength, Md, in a beam and the external action, M, shall satisfy

$$M \leq M_d$$

where

M_{d} = $M_{\text{n}}/\gamma_{\text{m0}}$ = design flexural resistance calculated as given below;

γ_{m0} = partial safety factor against flexural failure (Table 7); and

M_{n} = nominal ultimate flexural resistance.

8.3.5.2 Considering local buckling, sections are to be analyzed as plastic, compact or semi-compact with the following additional consideration:

a) Load history and development in composite action are to be taken into consideration with appropriate values of the modular ratio, *m* at each stage, and stresses and deflections are to be the summation of values over successive stages;

b) Determination of bending resistance for a beam before composite action has set in or during the construction stage shall be done as per good practice [C-6B(3)];

c) The structural steel reinforcement and concrete fully interact with full shear transfer between the concrete and structural steel under composite action;

d) The effective width of concrete in composite action may be as mentioned in **8.3.3**;

e) For calculating the bending resistance of plastic, compact and semi-compact composite beams, the procedure presented in Annex B may be followed; and

f) The partial shear connection may be used in plastic and compact sections either for attaining economy without losing much in the moment capacity of the composite section or under conditions where the number of shear connectors required for full shear interactions cannot be provided. Requirements on the method of evaluating the bending resistance of partial shear connection are presented in **B-1.2**.

The bending moment and shear force distribution in continuous beams for secondary, as well as primary moment resistant frames/beams have to be determined by structural analysis.

8.3.5.3 *Design of structure for effect of lateral buckling on moment resistance*

Lateral buckling may govern the design under the following conditions:

a) At the construction stage, in the top flange closer to mid-span in both simply supported and continuous beams; and

b) At the construction and composite stage, in the bottom flange closer to support in continuous beams.

At the construction stage, the effect of lateral buckling on the bottom flange in a continuous beam shall be taken care of by considering cantilever action up to the point of inflection from the support.

If required, suitable horizontal bracings or members may be provided at the bottom flange to reduce the effective length of the compression flange near support. For beams that are provided with such bracings or members giving effective lateral restraint to the compression flange at intervals along the span, the effective lateral restraint shall be capable of resisting a force equal to 2.5 percent of the maximum force in the compression flange taken as divided equally between the numbers of points at which the restraint in bracing members occur. In beams supporting composite slabs, wherein the sheeting is welded to the top flange before concreting is done, the lateral restraint of the deck sheet may be considered.

The effective laterally unsupported length of compression flange of steel sections in sagging and hogging moment regions may be taken as given in as per good practice [C-6B(3)]. In sagging moment segments of composite beams, the concrete slab may be assumed to provide lateral support, provided an adequate shear connection between the slab and the beam is provided. In the hogging moment regions of composite beams, the effective length considering the rotational restraint provided by the slab to the top tension flange may be taken into account as given in **B-2**.

8.3.5.4 *Simplified design of continuous beams in buildings without lateral bracings*

Continuous composite beams (or composite beams within a frame) with plastic, compact, or semi-compact sections may be designed without any additional lateral bracings to the compression flange when the following conditions are satisfied:

a) The concrete slab on top should be adequately attached with shear connectors to the structural steel section and to at least one another parallel member top flange to facilitate inverted U-frame action that rotationally restrains bottom flange lateral buckling at hogging moment sections;

b) Adjacent span lengths of continuous beams should not differ by more than 20 percent of the shorter span length. Cantilever span length should not exceed 15 percent of the adjacent span length;

c) The loading on each span should be uniformly distributed, with the permanent design loads exceeding 40 percent of the total design load;

d) At each support of steel member, the bottom flange should be laterally restrained with a web bearing stiffener at that location; and

e) The maximum depth of steel beam sections should not exceed the value given in Table 8.

Table 8 Maximum Depth of Steel Beams in Composite Construction (In mm)

[*Clause* 8.3.5.4 (e)]

Sl No.	Type of Member	Nominal Yield Strength Limit of Structural Steel (MPa)							
		250		300		350		> 400	
		Un-cased	En-cased	Un-cased	En-cased	Un-cased	En-cased	Un-cased	En-cased
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)
i)	I Section	800	1 000	700	900	650	850	500	650
ii)	Parallel flange	600	800	550	750	400	600	270	430

8.3.6 *Design of Structural Steel Web against Vertical Shear Force*

8.3.6.1 The factored design shear force, V_d, in a composite beam due to external action, V, shall satisfy:

$$V \leq V_d$$

where

Vd = design shear resistance calculated as given below.

$$V_d = V_n/\gamma_{m0}$$

γ_{m0}= partial safety factor as mentioned in Table 7.

V_n = nominal ultimate shear resistance.

The vertical shear force is assumed to be resisted by the web of the steel section only unless the value for contribution from the reinforced concrete part of the beam has been established. The nominal shear resistance, Vn may be governed by plastic shear resistance or strength of the web or governed by shear buckling as given below:

a) *Plastic Shear Resistance*

The nominal plastic shear resistance of composite beams under pure shear shall be calculated as indicated in as per good practice [C-6B(3)], disregarding the contribution of the concrete slab. The shear resistance for I-sections, channels both for major axis bending and minor axis bending as well as for rectangular and circular hollow sections of uniform thickness shall be as per good practice [C-6B(3)].

b) *Shear Buckling Resistance*

Resistance to shear buckling shall be verified as specified in as per good practice [C-6B(3)]. The nominal shear resistance, Vn, of webs with or without intermediate stiffeners as governed by buckling may be evaluated as detailed in as per good practice [C-6B(3)] either using the simple post-critical method or tension field method. The contribution of encasing concrete to shear resistance may be considered and that of shear reinforcement can be considered provided they consist of closed-loop stirrups. The total shear may be shared between the structural steel section and encasing concrete in the ratio of their contribution to plastic moment capacity.

8.3.6.2 *Reduction in bending resistance under high shear force*

If V is less than 0.6Vd, reduction in the plastic bending resistance of the section need not be considered. When $V > 0.6V$d, the bending resistance is reduced as the contribution of the web to bending gets diminished. The reduced bending resistances of the following sections are given below:

a) *Plastic or compact section*

$$M_{dv} = M_d - \beta(M_d - M_{fd}) \leq (1.2\, z_e f_y)/\gamma_{m0}$$

where

β = $(2V/V_d - 1)^2$

M_d = plastic design moment of the whole section disregarding high shear force effect considering web buckling effects

V = factored applied shear force.

V_d = design shear resistance as governed by web yielding or web buckling

M_{fd} = Plastic design resistance of the area of the cross section excluding the shear area, considering partial safety factor γ_{m0}

b) *Semi-compact Section*

$$M_{\mathrm{dv}} = Z_{\mathrm{e}} f_{\mathrm{y}} / \gamma_{\mathrm{mo}}$$

where

Z_e = elastic section modulus of the whole section.

8.3.7 *Hybrid Sections*

Use of hybrid steel sections consisting of different grade steel elements is permitted. The plastic and compact section design strength is obtained by using the appropriate value of yield stress in the different elements of the hybrid section. The design strength of the semi-compact section is evaluated with necessary adjustment (reduction) in stresses of the flange element in the cross-section with higher yield stress by the reduction factor, R_h. The R_h may be determined using the procedure as presented in **B-3** of Annex B.

8.3.8 *Partially Encased Sections*

This section is applicable for partially encased composite plastic or compact beams, provided the web depth to thickness ratio, d/t_w, is less than or equal to 117ε.

The full shear connection between the structural steel section and concrete encasing the web shall be ensured. The steel reinforcement in the compression zone and concrete in the tension zone may be disregarded.

The partial shear connection may be used in the partially encased composite section, provided the requirements of **8.3.5.2** are satisfied.

9 DESIGN FOR SERVICEABILITY LIMIT STATES

9.1 General

9.1.1 Serviceability limit states are related to the criteria governing normal use. Serviceability limit state is the limit state beyond which the serviceability criteria specified below are no longer met:

a) Stress and deflection limit;

b) Vibration limit;

c) Durability consideration; and

d) Fire resistance

9.1.2 Linear elastic analysis is used for finding out design moments and stresses under various load combinations and load factors, as mentioned in Table 7, for serviceability limit states. Concrete is assumed as unreinforced and un-cracked for the analysis.

9.1.3 *Method of Construction*

The stress and strain at serviceability limit state depend on whether the steel beam is propped or un-propped during construction, as given below:

a) *Un-propped construction* — In un-propped construction, the steel beam has to carry the construction load, including shuttering, wet concrete and its own weight until the concrete hardens;

b) *Propped construction* — In propped construction, both the dead and imposed load are resisted by the composite section. When props are used, they should be kept in place until the *in-situ* concrete has attained a strength equal to approximately twice the stress to which the concrete may be subjected to upon removal of props; and

c) *Non-composite construction* — In non-composite construction, the concrete slab is designed according to [C-6B(2)] and the steel deck sheet act just as a permanent shuttering.

The difference in the method (a) and (b) of construction does not, however, affect the ultimate limit load, wherein the total load, including the transient loads, shall be resisted by the composite section.

9.2 Negative Moments

Negative moments over intermediate supports may be adjusted as mentioned in **8.1.2.1**.

9.3 Stresses and Deflections

For calculating stresses at service load and deflection, the value of the modular ratio, *m* shall be taken as,

$m = \frac{E_s}{E_{cm}} \geq 7.5$ For short-term effect or loading.

$m = \frac{E_s}{K_c E_{cm}} \geq 15.0$ For permanent or long-term loads.

where

K_c = Creep factor, 0.5

E_s = Modulus of elasticity for steel = 2.0×10^5 N/mm^2;

E_{cm} = Modulus of elasticity of cast *in-situ* concrete as per Annex F;

f_{ck} = characteristic cube compressive strength of concrete in N/mm^2; and

E_{ci} = Modulus of elasticity of cast *in-situ* concrete at *i* days ($i < 28$ days).

The equivalent area of concrete slab at any stage shall be determined by dividing the effective width of the concrete slab by the modular ratio as given below.

$$m = \frac{E_s}{E_{ci}}$$

Final stresses and deflection are to be worked out separately at each stage of load history with relevant modular ratios and section modulus as discussed above and then added together.

9.3.1 *Limiting Stresses for Serviceability*

Limiting stresses for different stages of construction are as indicated below:

a) Concrete — The limiting compressive stress in concrete should not exceed one-third of the characteristic strength of concrete;

b) Reinforcement Steel — The limiting tensile stress in steel reinforcement should not exceed f_{yk}/γ_k; and

c) Structural Steel — The limiting stress in steel beam considering the different stages of construction should not exceed f_y/γ_{mo}.

Where bearing stress is combined with tensile or compressive stress, bending and shear stresses under the most unfavourable conditions of loading, the equivalent stress obtained from the following equation shall not exceed $0.9f_y$:

$$f_{ec} = \sqrt{f_{bc}{}^2 + f_p{}^2 + f_{bc}.f_p + 3\tau_b{}^2}$$

and

$$f_{et} = \sqrt{f_{bt}{}^2 + f_p{}^2 + f_{bt}.f_p + 3\tau_b{}^2}$$

where

f_{ec} and f_{et} = equivalent compressive and tensile stress in steel section;

f_{bc} and f_{bt} = actual compressive and tensile stress in steel section;

f_p = actual bearing stress in steel section; and

τ_b = actual shear stress in steel section.

The value of bending stresses f_{bc} about each axis, to be used in the above formula, shall be individually lesser than the values of the maximum allowable stresses in bending about the corresponding axis.

9.3.2 *Limiting Deflection and Camber*

9.3.2.1 *Deflection limit*

The deflection under serviceability loads of a building or a building component should not impair the strength of the structure or components or cause damage to finishing. Deflections are to be checked for the most adverse but realistic combination of service loads and their arrangements by elastic analysis using a load factor given Table 6. The deflection of a member shall be calculated without considering the impact factor or dynamic effect of the loads on deflection. As per good practice [C-6B(3)] gives recommended limits of deflections for certain structural members and systems. Circumstances may arise where greater or lesser values would be more appropriate depending upon the nature of the material in element to be supported (vulnerable to cracking or not) and intended use of the structure, as required by the client.

9.3.2.2 *Provision of camber*

Where the deflection due to the combination of dead load and imposed load is likely to be excessive, consideration should be given to pre-camber the steel beams. The values of desired camber shall be specified in the design drawing. Generally, for spans greater than 25 m, camber approximately equal to the deflection due to dead loads plus half the imposed load may be used.

9.4 Vibration

Suitable provisions in the design shall be made for the dynamic effects of imposed loads, impact loads and vibration due to machinery operating loads. In severe cases, the possibility of resonance, fatigue or unacceptable vibrations shall be investigated. Unusually flexible structures (generally the height to the effective width of lateral load resistance system exceeding 5 : 1) shall be investigated for lateral vibration under dynamic wind loads as per(*see* Part C 'Structural Design/Section 1 Loads and Load effects' of this NBCS). Structures subjected to a large number of cycles of loading shall be designed against fatigue failure in accordance with as per good practice [C-6B(3)]. The floor vibration effect shall be considered using specialist literature.

9.5 Durability

9.5.1 Several factors that affect the durability of the buildings under conditions relevant to their intended life are listed below:

a) The environment;

b) The degree of exposure;

c) The shape of the member and the structural detail;

d) The protective measure; and

e) Ease of maintenance.

The durability of the structural steel component of a composite section shall be ensured by recommendations as given in as per good practice [C-6B(3)]. Specialist literature may be referred to for more detailed additional information in design for durability. For concrete, the durability shall be ensured by following the recommendations as given in as per good practice [C-6B(2)].

9.5.2 *Profiled Steel Sheeting for Composite Slabs*

The durability criteria for profiled steel sheets of composite deck slab shall be met by the following procedures:

a) The exposed surfaces of the steel sheeting shall be adequately protected to resist particular atmospheric conditions; and

b) A zinc coating of a total mass 275 g/m^2 (including both sides) is sufficient for internal floors in a non-aggressive environment, but the specification may be varied depending on service conditions.

9.6 Fire Resistance

Fire resistance of a steel component of a composite member is a function of its mass, its geometry, and the actions to which it is subjected, its structural support conditions, fire protection measures adopted and the fire to which it is exposed. Design provisions to the resistance of fire for concrete shall be as per guidelines given in as per good practice [C-6B(2)]. For the design of structural steel components for fire resistance, as per good practice [C-6B(3)] shall be referred. Specialist literature may be referred to for more detailed information on the design for fire resistance of steel/composite structures. The aspect of fire resistance is given in **15**.

9.7 Control of Cracking in Concrete and Crack Width Calculation

Minimum reinforcements in terms of diameter and spacing required for crack control at the top of concrete as per good practice [C-6B(2)] are to be provided in composite beams at the zone of the negative moment to prevent cracks adversely affecting the appearance and durability of the structure. Crack width calculation as well as limiting crack width as given in as per good practice [C-6B(2)] may be followed, subject to the discretion of engineers. The crack width in concrete shall be restricted to values as indicated in as per good practice [C-6B(2)].

10 DESIGN FOR FATIGUE LIMIT

This section applies to the design of structures and structural elements subject to loading which could lead to fatigue failure. The following effects are not considered in the section:

a) Corrosion fatigue;

b) Low cycle (high stress) fatigue;

c) Thermal fatigue;

d) Stress corrosion cracking;

e) Effects of high temperature (> 150 °C); and

f) Effects of low temperature (< below transition temperature).

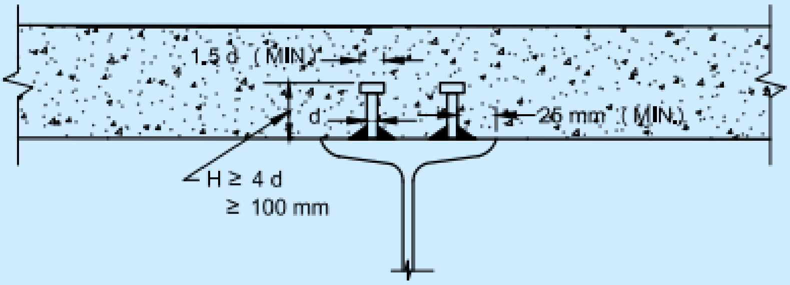
The fatigue design of various components of composite structures like members, welded joints, bolts, shear lugs etc. shall be carried out as per the specifications laid down in as per good practice [C-6B(3)]. Fatigue provisions in the design of shear connectors are discussed in **11.3**.

11 SHEAR CONNECTORS

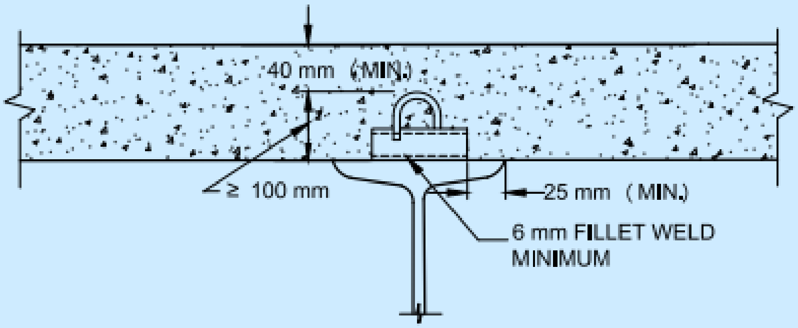
The shear connectors shall fulfill the dual purpose of transferring shear force between concrete and structural steel as well as anchoring the two components relative to each other with minimum slip to ensure full or partial composite action as per the design requirement. The dimensional details of shear shall be as given in Fig. 8.

11.1 Longitudinal Shear in Beams and Slabs

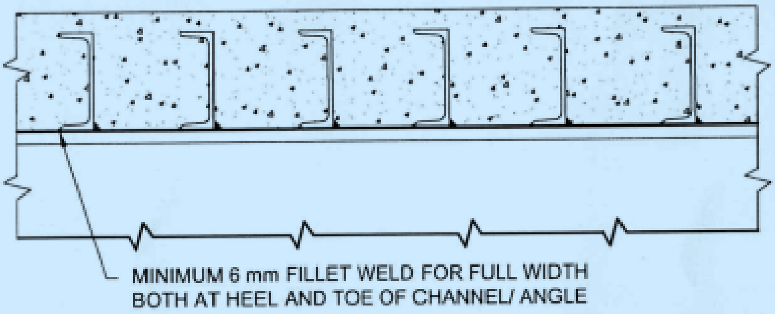
Longitudinal shear load on shear connectors in a composite section, irrespective of boundary conditions of the members, is to be calculated for service and fatigue limit states on the basis of elastic theory. Appropriate sectional properties based on effective widths and modular ratios as per the load history and development of composite action shall be considered for the design of the section for resistance against longitudinal shear between steel and concrete.



(a) STUD CONNECTOR



(b) ANGLE / CHANNEL CONNECTOR - TRANSVERSE SECTION



MINIMUM 6 mm FILLET WELD FOR FULL WIDTH
BOTH AT HEEL AND TOE OF CHANNEL/ ANGLE

FIG. 8 DETAILS OF SHEAR CONNECTORS

NOTES

1 The diameter of the stud connector welded to the flange plate shall not exceed two and half times the flange plate thickness.

2 The height of the stud connectors shall not be less than four times their diameter nor 100 mm.

3 The diameter of the head of the stud shall not be less than one and a half times the diameter of the stud and the depth shall not be less than 0.4 d.

4 The size of the fillet weld joining other types of connectors to the flange plate shall not exceed half the thickness of the flange plate.

5 Channel and angle connectors shall have at least 6 mm fillet welds placed along the heel and toe of the channels/angles. The clear distance between the edge of the flange and the edge of the shear connectors shall not be less than 25 mm.

6 The overall height of a connector, including any hoop, which is an integral part of the connector, shall be at least 100 mm with a clear cover of 25 mm.

11.2 Design Strength of Shear Connectors

Shear connectors shall be checked for adequacy against failure in both ultimate limit states and fatigue limit states. The strength of shear connectors against failure under ultimate limit states and fatigue limit states shall be considered as per 11.2.1, 11.2.2 and 11.3, respectively.

11.2.1 *Design Strength of Shear Connectors*

Design static strengths of flexible shear connectors, mainly stud connectors and channel connectors can be determined by the following equations:

a) *Stud connectors*

The design resistance, Q_d of stud shears connectors shall be as given below:

$$Q_\mathrm{d} = \frac{0.8 f_{us}.\pi.d^2/4}{\gamma_\mathrm{mv}} \leq \frac{0.29\ \alpha\ d^2\sqrt{0.8\ f_\mathrm{ck}.E_\mathrm{cm}}}{\gamma_\mathrm{mv}}$$

where

$$\alpha = 0.2\left\{\frac{h_\mathrm{s}}{d}+1\right\} \text{ for } 3 \leq \frac{h_\mathrm{s}}{d} \leq 4 \text{ and } \alpha = 1.0 \quad \text{for } \frac{h_\mathrm{s}}{d} > 4;$$

Q_d = design strength of stud in, Newton (N);

γ_{mv} = partial safety factor for stud connector = 1.25;

d = diameter of the shank of the stud, in mm (16 mm ≤ d ≤ 25 mm);

f_us = ultimate tensile strength of the stud material $\leq$ 500 N/mm^2;

f_ck = Characteristic compressive strength of concrete of density not less than 1750 kg/m^3;

h_s = nominal height of stud in mm; and

E_{cm} = Secant modulus of elasticity of concrete (*see* Annex F).

b) *Channel Connectors*

Assuming that the web of the channel is placed vertical and the shear applied is nominally perpendicular to the web, the design resistance of a channel connector shall be determined as given below:

$$Q_d = \frac{\left[20b(h)^{3/4}\right](0.8f_\mathrm{ck})^{1/3}}{\gamma_{mv}}$$

where

Q_d = Design strength of channel in Newton (N);

h = height of the channel in mm;

b = length of the channel in mm;

f_ck = Characteristic compressive strength of concrete in MPa; and

γ_{mv} = factor for channel shear connector = 1.25.

While using the channel shear connectors, the following recommendations need to be followed:

a) The height h of the channel should not exceed 20 times the channel web thickness or 150 mm, whichever is less;

b) The width b of the channel should not exceed 300 mm;

c) The underside of the top flange of the channel should not be less than 30 mm clear above the bottom reinforcement; and

d) The size of the fillet weld connecting the channel to the flange plate should not exceed half the flange plate thickness.

11.2.2 The design strengths of some standard shear connectors are given in Table 9. The following points have to be considered while using Table 9:

a) $f$ck is the specified characteristic cube strength at 28 days;

b) Connector strengths for concrete of intermediate grade may be obtained by linear interpolation;

c) For channels of lengths different from those quoted above, the capacities are proportional to the lengths greater than 150 mm;

d) For rolled angle and tee shear connectors, the values given for channel connectors are applicable, provided the height is at least equal to that of the channel;

e) For stud connectors of overall height greater than 100 mm, the design static strength should be taken as the values given in Table 9 for 100 mm high connectors;

f) The above provisions of stud connectors are not applicable to composite slab using a profiled deck. The strength of the shear connector in such cases is given in **11.2.3**;

g) The number of shear connectors given by the above Table 9 shall be distributed in the zone between the maximum and the zero moment sections. The number of connectors has to meet both ultimate strength consideration as well as fatigue consideration; and

h) In order to avoid undesirable slip, the maximum interface shear per unit length due to superimposed dead load and imposed load under service conditions at any point in the beam should satisfy **11.3.1**.

Table 9 Ultimate Static Design Strengths of Shear Connectors (*Q*n for Different Concrete Strengths)

(*Clause* 11.2.2 *and* 11.3.1)

Sl No.	Type of Connector	Material	Size		Ultimate Static Strength in kN per connector			
			Nominal diameter mm	Nominal height mm	For concrete strengths, f_{ck} MPa

			ISMC 100		206	219	241	260
			ISMC 75		166	176	194	209

11.2.3 *Design Resistance of Studs Used with Profiled Steel Sheeting*

11.2.3.1 *Sheeting with ribs parallel to the supporting beams*

The studs are located within a region of concrete that has the shape of a haunch (Fig. 9). When the sheeting is continuous across the beam, the width of the haunch b_0 is equal to the width of the trough, as given in Fig. 10. Where the sheeting is not continuous, b_0 is as given in Fig. 9. The depth of the haunch should be taken as d_p, the overall depth of the sheeting excluding embossments.

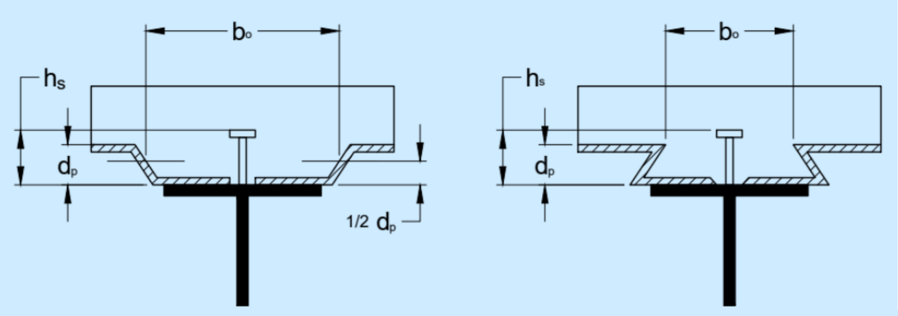

FIG. 9 BEAM WITH PROFILED DECKING SHEET RIBS PARALLEL TO THE BEAM

The design resistance of the shear connector should be taken as the resistance in a solid slab, multiplied by the reduction factor k_p given by the following expression:

$$k_{\mathrm{p}} = 0.6\frac{b_0}{d_{\mathrm{p}}}\left(\frac{h_{\mathrm{s}}}{d_{\mathrm{p}}} - 1\right) \leq 1.0$$

Where h_s is the overall height of the stud, but not greater than d_p+75 mm.

Where the sheeting is not continuous across the beam, as shown in Fig. 9, the side of the haunch and its reinforcement shoud be taken as the depth of the profile d_p excluding the embossments.

11.2.3.2 *Sheeting with ribs transverse to the supporting beams*

Provided that the conditions given in **11.2.2** are satisfied, the design shear resistance should be taken as the resistance in a solid slab, calculated as given by **11.2.1** (except that f_{us} should not be taken as greater than 450 N/mm^2) multiplied by the reduction factor k_t given by:

$$k_{\mathrm{t}} = \frac{0.7}{\sqrt{n_{\mathrm{r}}}}\frac{b_0}{d_{\mathrm{p}}}\left(\frac{h_{\mathrm{s}}}{d_{\mathrm{p}}} - 1\right) \leq 1.0$$

where

n_r is the number of stud connectors in one rib at the beam intersection, not to exceed two in calculation of the reduction factor k_t and of the longitudinal shear resistance of the connection.

The factor k_t should not be taken greater than the appropriate value k_{tmax} given in Table 10. The values for k_t are applicable provided that: the studs are placed in ribs with a height d_p not greater than 85 mm and a width b_0 not less than d_p and for through deck welding, the diameter of the studs is not greater than 20 mm, or for holes provided in the sheeting, the diameter of the studs is not greater than 22 mm.

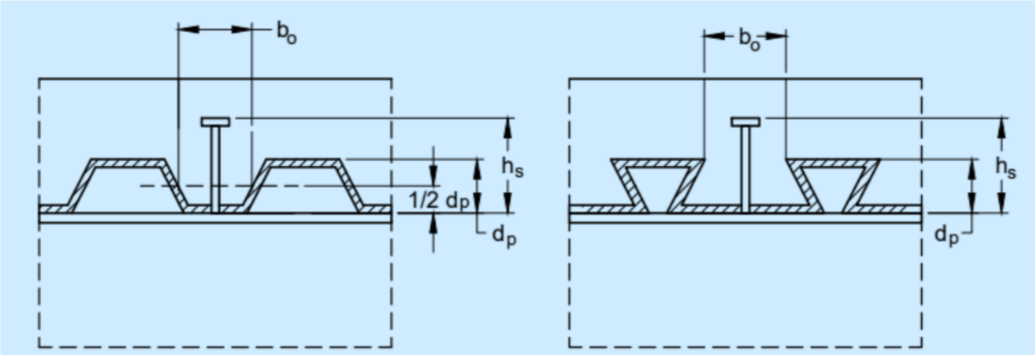

FIG.10 BEAM WITH PROFILED DECKING SHEET RIBS TRANSVERSE TO THE BEAM

		>1.0	1.0	0.75
ii)	n_r =2	≤1.0	0.70	0.60
		>1.0	0.8	0.60

11.3 Fatigue Strength of Shear Connectors

The fatigue shear stress range (fatigue Strength) of the shear connector shall be obtained from [C-6B(3)], corresponding to the design load life cycle, N_{SC}.

The strength shall be determined as given below:

$$\tau_f = \tau_{fn}\sqrt[5]{5\times10^6/N_{SC}}$$

τ_{fn} = design normal and shear fatigue stress range respectively of the detail for 5 × 10^6 cycles as given in [C-6B(3)].

τ_{fn} = 67 N/mm^2 for stud connector as per good practice [C-6B(3)].

τ_{fn} = 59 N/mm^2 for channel connector as per good practice [C-6B(3)] [provided that the thickness of the top flange of steel beam is greater than or equal to 12 mm and the edge distance from the end of weld to the edge of the top flange is 10 mm].

The design fatigue strengths of some standard shear connectors are presented in Table 11.

Table 11 Fatigue Strengths Qr (in kN)

(*Clause* 11.3)

Sl No.	Type of Connectors (Headed Stud – Diameter)	Connector Material	N = Nos. of Cycles in Millions				
			0.1	0.5	2	10	100
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
i)	Headed studs φ 25	f_{ys} = 385 MPa f_{us} = 495 MPa Elongation = 18 percent	72	52	40	29	18
ii)	Headed studs φ 22		56	40	31	22	14
iii)	Headed studs φ 20		46	33	25	18	12
iv)	Headed studs φ 16		29	21	16	12	7
v)	Channel 150 long for a nominal weld of 8 mm	[C-6B(4)]	108	79	60	43	27

NOTE — For intermediate stress cycles the values may be interpolated from log scales (that is, the above equation). Other connectors, if used, should have their capacities established through tests.

11.3.1 *Spacing of Shear Connectors*

The design shear action per unit length of the steel concrete interface, V_L, is given by:

$$V_L = \sum \left[\frac{VA_{ec}y}{I}\right]_{DL,IL}$$

where

V_L = Longitudinal shear per unit length;

V = The factored vertical shear forces due to dead load and imposed load (including impact if any) separately at each state of load history;

A_{ec} = The transformed compressive area of concrete above the plastic neutral axis of the composite section with the appropriate modular ratio depending on the nature of load (short term that is, imposed load, or long term, that is, dead load);

y = C.G. distance of transformed concrete area from the plastic neutral axis;

I = Moment of Inertia of the composite section using an appropriate modular ratio; and

DL, IL = Different load history conditions, that is, sustained load or composite action dead load, transient load, or composite action imposed load. These loads are to be considered with appropriate load factors at this stage.

Maximum spacing of shear connectors, S_{L1} is given as

$$S_{L1} = \frac{\sum Q_n}{V_L}$$

Q_n is the ultimate static strength of one shear connector (Table 9) and the summation is over the number of shear studs in one section.

The maximum longitudinal force at the interface due to bending moment shall also be calculated over the shear span, *L,* equal to the distance from zero moment to maximum moment section and is given by the following equations:

$$H_1 = A_{sl} f_y \times 10^{-3} / \gamma_{m0}$$

$$H_2 = 0.36 f_{ck} A_{ec} \times 10^{-3}$$

where

H_1, H_2 = Longitudinal interface shear force due to bending (kN);

A_{sl} = Area of tensile steel (mm^2) in the longitudinal direction;

A_{ec} = Effective area of concrete:

$b_{eff}.x_u$ (for neutral axis within the slab); and

$b_{eff}.\ d_s$ (for the neutral axis in the steel section)

Sufficient connectors should be provided to resist the longitudinal force *H*, the maximum compressive force action in the composite beam slab interface, which is the smaller of H_1 and H_2.

The maximum spacing of shear connectors, S_{L2}, is given as:

$$S_{L2} = \frac{\sum Q_n}{H} . L$$

11.3.2 *Fatigue Strength of Shear Connectors*

$$V_r = \Sigma \left[\frac{V_R . A_{ec} . y}{I}\right]_{LL}$$

where

V_R = The shear range in which is the difference between the maximum and minimum vertical shear envelop due to imposed load and impact; and

H = is imposed load with impact.

V, Aec, y and I are as explained above

Spacing of shear connectors from fatigue consideration is given as:

$$S_R = \frac{\Sigma Q_r}{V_r}$$

Q_r is the design fatigue strength of one shear connector, which is to be taken from as per good practice [C-6B(3)] Table 10.

For full shear connection, the lowest spacing of S_{L1}, S_{L2}, and S_R is to be provided as the actual spacing of the shear connectors.

11.4 Partial Shear Connection

11.4.1 Partial shear connection may be used either for attaining economy without losing much in the moment capacity of the composite section or where the number of shear connectors required for full shear cannot be provided without compromising minimum spacing provisions.

Partial shear connections may be used in plastic and compact sections. The number of connectors n_p shall then be determined by a partial shear connection theory, taking into account the deformation capacity of the shear connector.

$$S_c \text{ degree of shear connection} = \frac{n_p}{n_f}$$

n_p = Number of shear connectors provided for partial shear connection;

n_f = Number of shear connectors required for full shear connection;

M_R = Required reduced bending resistance of the section;

M_d = The fully plastic moment of resistance of the composite section; and

M_{ps} = Plastic moment of resistance of steel section alone.

$$n_p = \frac{M_R - M_{ps}}{M_d - M_{ps}} n_f$$

11.4.2 *Limitation on the Use of Partial Shear Connection in Beams for Buildings*

Headed studs with an overall length after welding not less than 4 times its diameter and with shank diameter not less than 16 mm and neither greater than 25 mm may be considered as ductile with the following limits for the degree of shear connection, S_c:

a) For steel sections with equal flanges:

$$L_e \leq 25: S_c \geq \; 1 - 1.42\varepsilon^2\,(0.75 - 0.03L_e);\, S_c \geq 0.4$$

$$L_e > 25: S_c = 1.0$$

b) For steel sections having a bottom flange with an area of three times the area of top flange:

$$L_e \leq 20: S_c \geq 1 - 1.42\varepsilon^2\,(0.30 - 0.015L_e);\;\; S_c \geq 0.4$$

$$L_e > 20: S_c = 1.0$$

where

$\epsilon = \sqrt{250/f_y}$, L_e is the distance between points of zero bending moment in the sagging bending range in metres. For typical continuous beams, L_e may be assumed as shown in Fig. 6 and Fig. 7.

c) For steel sections having a bottom flange with an area exceeding the area of the top flange but less than three times that area, the limit for S_c may be determined from expressions in (a) and (b) above by linear interpolation.

11.5 Precautions against Separation of Steel Beam from Concrete

a) Where a concrete haunch is used, between the steel flange and the soffit of the slab, top of stud and top flange of channel shear connectors shall extend up to at least 40 mm above the transverse reinforcements in the haunches, provided the reinforcements are sufficient to transfer longitudinal shear; and

b) Where shear connectors are placed adjacent to the longitudinal edge of the slab, transverse reinforcement provided in accordance with **11.7** shall be fully anchored in the concrete between the edge of the slab and the adjacent row of connectors.

11.6 Detail of Haunches in Reinforced Concrete

11.6.1 Figure 11 indicates the dimension of haunches as applicable for slabs with haunches resting on steel beam. The edge of haunches shall be located outside a line drawn at 45 degrees from the outside edge of the base of the connector, as shown in Fig. 11.

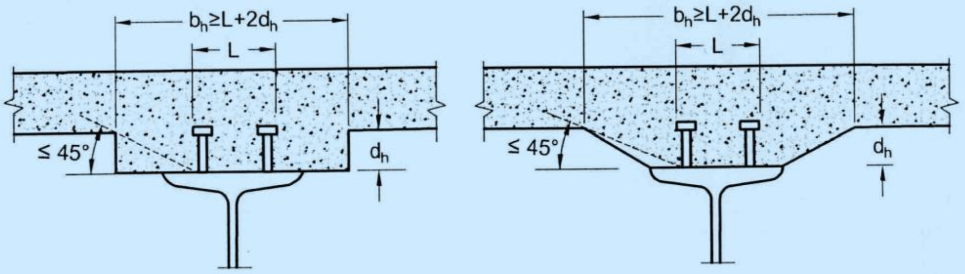

FIG. 11 DIMENSION OF HAUNCHES

11.6.2 *Clear Cover to Shear Connectors*

The clear depth of concrete cover over the top of the shear connectors shall not be less than 25 mm. The horizontal clear concrete cover to any shear connector shall not be less than 50 mm as shown in Fig.12.

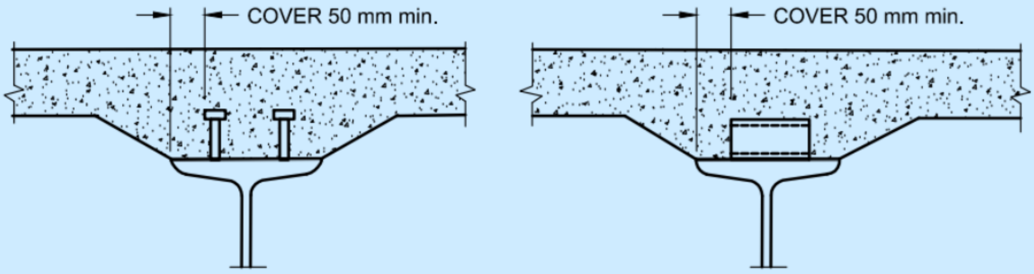

FIG. 12 CLEAR COVER TO SHEAR CONNECTORS

11.6.3 *Spacing of Shear Connectors*

Where the compression flange of steel beam, in spite of being semi-compact is assumed to be compact or plastic based on the restraint provided by shear connectors, the centre-to-centre spacing of the shear connectors in the direction of the compression should satisfy the following:

a) Where the slab is in contact over the full length (for example, solid slab)

$$S_{\mathrm{L}} < 21 \cdot t_{\mathrm{f}} \, . \, \varepsilon$$

b) Where the slab is not in contact over the full length (for example, slab with ribs transverse to the beam):

$$S_{\mathrm{L}} < 14 \cdot t_{\mathrm{f}} \, . \, \varepsilon$$

where

$\varepsilon = \sqrt{250/f_{\mathrm{y}}}$

t_{f} = thickness of the flange;

f_{y} = nominal yield strength of the flange in N/mm^2; and

S_{L} = maximum spacing of the shear connector.

In addition, the clear distance from the edge of the compression flange to the nearest line of shear connectors should not be greater than $9t_{\mathrm{f}} \ \varepsilon$ or 50 mm, whichever is less.

In all cases, a shear connector shall be provided throughout the length of the beam and may be uniformly spaced between critical cross sections. The maximum longitudinal spacing of the shear connectors shall be limited to the lesser of 600 mm or 3 times the total slab thickness or four times the height of the connector (including any hoop which is an integral part of the connector), whichever is least.

Minimum spacing should be such as to allow proper concrete flow and compaction around the connectors. In stud connectors, the minimum spacing should not be less than 75 mm.

11.7 Transverse Shear Check (Requirement of Bottom Steel in Concrete Slab)

Planes, which are critical for longitudinal shear failure in the process of transfer of longitudinal shear from the beam to the slab are of four main types as shown in Fig. 13. The shear force Q in kN/m of beam is given by:

$$Q = \frac{N_{\mathrm{r}} \, Q_{\mathrm{u}}}{S_{\mathrm{L}}}$$

where

N_{r} = Number of shear connection at a section;

Q_{u} = Design strength one shear connector; and

S_{L} = Longitudinal spacing of connector in meter.

The shear force transferred per metre length from steel beam to concrete slab above, V_{L} shall satisfy both the following conditions:

a) $V_{\mathrm{L}} \leq 0.623 \, L\sqrt{f_{\mathrm{ck}}}$; or

b) $V_{\mathrm{L}} \leq 0.232 \, L\sqrt{f_{\mathrm{ck}}} + 0.1. A_{\mathrm{st}}. f_{\mathrm{yk}}. n$

where

V_{L} = Longitudinal shear force per unit length calculated for the ultimate limit state;

f_{ck} = Characteristic strength of concrete, in MPa;

f_{yk} = Yield stress of transverse reinforcement, in MPa;

L = Length (in mm) of possible shear planes; for two rows of shear studs as shown in Fig.15, $L = 2\,h_s + b_0$;

n = Number of times each lower transverse reinforcing bar is intersected by a shear surface (that is, the number of rows of shear the connector at one section of the beam). Generally, for T-beam n = 2 and for L-beam n = 1; and

A_{st} = Sectional areas (in cm^2) of transverse reinforcements per meter run of the beam. The amount of transverse steel (cm^2/m) in the bottom of the slab shall not be less than $\frac{2.5Q}{f_{yk}}$.

11.8 General Arrangements of Transverse Reinforcements

11.8.1 If the concrete by itself is insufficient to take the longitudinal shear, sufficient transverse reinforcements shall be provided to transfer longitudinal shear force from the beam to the effective width of the slab. The area of transverse reinforcement per unit length of the beam will be the sum total of all the reinforcement [A_t, A_b or A_h, as shown in Fig. 14(a), Fig. 14(b) and Fig. 14 (c)], which are intersected by the shear plane and are fully anchored on both the sides of the shear plane considered.

(c) STUD CONNECTORS IN HAUNCHED BEAM (d) CHANNEL CONNECTORS IN HAUNCHED BEAM

FIG. 13 ARRANGEMENT OF TRANSVERSE REINFORCEMENTS

11.8.2 *Total Transverse Reinforcements*

The total transverse reinforcements Ast· per unit length of the beam in case of shear plane 1 – 1, which crosses the whole thickness of the slab, will be the sum of (A_t + A_b) [Fig. 14(a)]. Area of reinforcements A_t and A_b include those provided for flexure. The total transverse reinforcements across plane 2-2 [Fig. 14(a)] is $A_{st} = 2\,A_b$ and that across plane 3-3 [Fig. 14(b)] is $Ast = 2Ah$ as these planes do not cross the full thickness of the slab. In the case of shear plane 4 – 4 [Fig. 14(c)], the total transverse reinforcement is $Ast = 2(A_h + A_b)$. The transverse reinforcements shall be placed at locations as shown in Fig. 14. The haunch bars shall be extended beyond the junction of bottom bars by a length equal to the anchorage length.

FIG. 14 TRANSVERSE REINFORCEMENTS ALONG SHEAR PLANES

12 COMPOSITE SLABS WITH PROFILED STEEL SHEETING

12.1 General

The provisions in this section deal with composite floor slabs spanning only in the direction of ribs of the decking. The provisions are applicable in buildings, wherein the slabs are subjected to predominantly static imposed loads. The application of the provision is limited to narrowly spaced web, which is defined by the ratio of the width of the sheet rib to the rib spacing $b_r/b_p \leq 0.6$ (*see* Fig. 15).

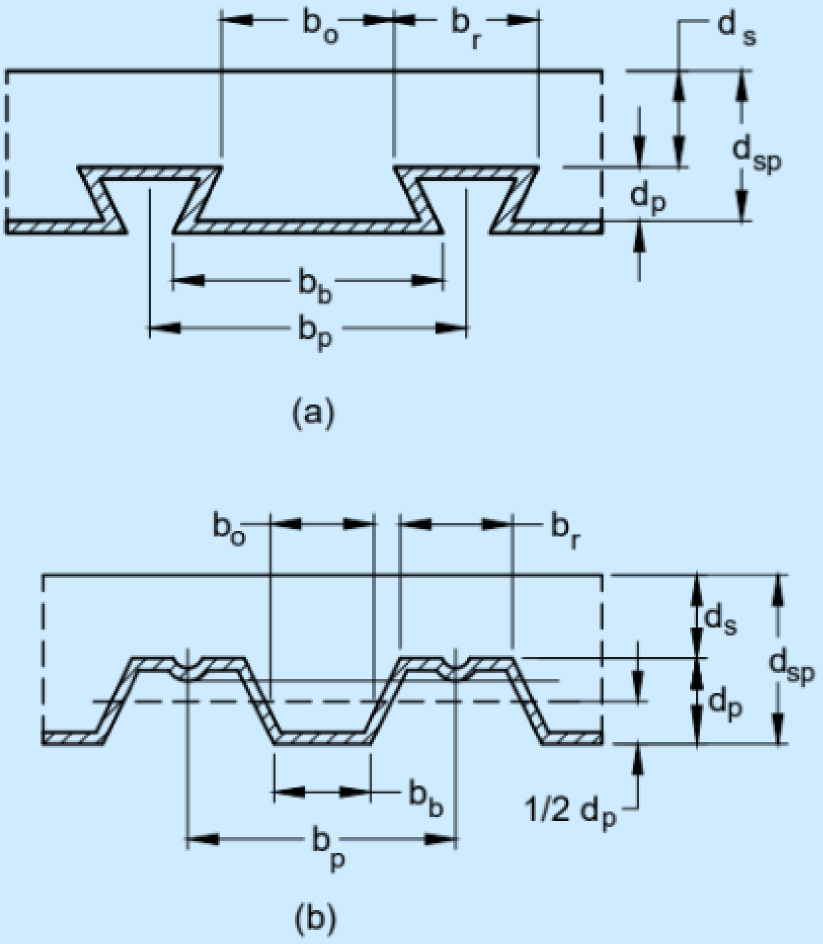

FIG. 15 PROFILE DIMENSION FOR COMPOSITE SLABS.

12.2 Prequalifications

12.2.1 *Prequalification of Slab dimension*

The prequalification of composite and non-composite slabs are presented below:

a) Where the slab acts composite with a steel beam or used as a diaphragm:
  1) the overall depth of the slab should not be less than 90 mm; and
  2) the thickness of concrete above the main top flat surface of the sheeting ribs should not be less than 50 mm.

b) Where the slab does not act composite with a steel beam or has no other stabilizing function:
  1) the overall depth of the slab should not be less than 80 mm; and
  2) the thickness of concrete above the main flat top surface of the sheeting ribs should not be less than 40 mm.

12.2.2 *Bearing Length*

The recommended minimum bearing lengths of steel decking on the support (L_{bs}) and the composite slab, including the cast in place concrete (L_{bs}) shall be as given in (*see* Fig. 16):

a) For composite slab bearing on steel or concrete: L_{bc}=75 mm, L_{bs}=50 mm; and

b) For composite slab bearing on other material: L_{bc}=100 mm, L_{bs}= 70mm.

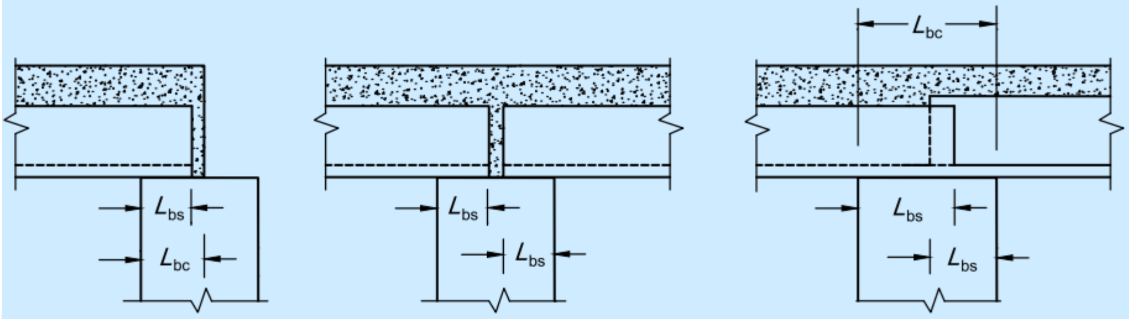

FIG. 16 MINIMUM BEARING LENGTHS

12.2.3 *Reinforcement for Shrinkage and Temperature Stresses*

The effect of temperature stress in composite slabs in buildings is normally neglected unless required in special conditions. The effect of shrinkage is to be considered. The total shrinkage strain for design may be taken as 0.000 3 in the absence of test data.

12.2.4 *Minimum Reinforcement*

The minimum reinforcement in either direction should be according to [C-6B(2)]. The spacing of the reinforcement bar should be in accordance with as per good practice [C-6B(2)].

12.2.5 *Size of Aggregates*

In addition to the above, the largest nominal aggregate size should be according to as per good practice [C-6B(2)].

12.3 Analysis for Internal Forces and Moments

12.3.1 *Analysis of Profile Steel Sheeting as Shuttering*

a) The elastic analysis shall be used where sheeting is considered. The design based on the elastic distribution of bending moment is conservative, as it does not take into account of redistribution of moments that can occur between support and mid span sections;

b) In the analysis of propped profile steel sheeting, the magnitude of bending moments and shear forces could be conservatively calculated by using the coefficients of bending moment and shear force as per good practice [C-6B(2)] ;

c) More accurate analysis and design of profile steel sheeting as a shuttering should be in accordance with as per good practice [C-6B(18)] ;

d) If the deflection at the center of the shuttering due to its own weight and the wet weight of concrete is less than (1/10) of the depth of the composite slab, the effect of 'ponding' due to shuttering deflection can be disregarded. Otherwise, that effect of additional load shall be evaluated by taking the additional uniform depth of concrete over the span as 0.7 times the central deflection. Ponding is explained in C-3'

e) The effect of ponding, especially in longer span, can be reduced by propping the shuttering during concreting until the concrete hardens. Plastic redistribution of moments in the propped shuttering is not allowed in evaluating stresses due to self-weight and wet concrete weight.

12.3.2 *Analysis of Composite Slab*

a) The application of linear methods of analysis is suitable for the serviceability limit states as well as for the ultimate limit states. Plastic methods shall be used only in the ultimate limit state;

b) The following method of analysis may be used for ultimate limit states:

1) Linear analysis without redistribution (serviceability limit state), and with redistribution (Ultimate limit state). If the effects of cracking of concrete are neglected in the analysis for ultimate limit states, the hogging bending moments at internal supports may be optionally reduced by up to 30 percent and corresponding increases are made to the sagging bending moments in the adjacent spans;

2) Rigid-plastic global analysis may be used provided it is shown that sections where plastic rotations are required have sufficient rotation capacity. Plastic analysis without any direct check on rotation capacity may be used for the ultimate limit state if reinforcing steel satisfying the ductility requirement in **6.2.3** is used and the span length is not greater than 3.0 m. (Ultimate limit state); and

3) Elastic-plastic analysis accounting for the non-linear material behavior. (Ultimate limit states).

c) A continuous slab may be designed as a series of simply supported spans. Nominal reinforcement should be provided in accordance with as per good practice [C-6B(2)], over the intermediate supports to manage crack size; and

d) Concentrated loads may be assumed to be distributed over an effective width of the slab, assuming the load is distributed at an angle of 45° to the horizontal up to the top surface of the decking.

12.4 Design of Composite Slabs

Proprietary data backed by analysis and tests may be used in the design. Otherwise, the procedure given below may be used to evaluate the strength of composite slabs.

12.4.1 *Effective Span*

a) When a continuous composite slab is designed as a series of simply supported spans, for simplicity, the effective span can be taken as the lesser of the following:

1) Distance between centres of the supports; and

2) The clear span plus the effective depth of the slab.

b) Where the composite slab is designed as continuous, it is permitted to use an equivalent isostatic span for the determination of the resistance. The span length should be taken as:

1) 0.8 L for internal span (effective span L); and

2) 0.9 L for external span (effective span L).

12.4.2 *Design of Profile Steel Sheeting as Shuttering During Construction*

The stress analysis of the profiled steel sheeting should be evaluated using the design equations or tests. For the ultimate limit state, the resistance of the sheet to sagging and hogging bending, together with the effects of combined bending and web crushing, are normally critical:

a) For the serviceability limit state, the limiting value of deflection $\delta_{\max}$ of steel sheeting under its own weight plus the weight of wet concrete may be considered as $L/180$ (where L is the effective span between supports) as per good practice [C-6B(3)];

b) Profiled decking acting alone resists construction, dead, and imposed load until the concrete hardens and gains strength. 'Ponding' effect, especially in long spans due to excessive deflection of decking, has to be accounted while evaluating design forces and design strength unless sufficient propping is provided during the construction stage until the concrete hardens; and

c) The longer spans will require propping to eliminate substantial deflection. Otherwise, a significant increase in concrete weight due to ponding has to be accounted.

12.4.3 *Design of Composite Slab for the Ultimate States*

The bending moment and shear force distribution in continuous beams for secondary, as well as primary moment resistant frames/beams, have to be determined by structural analysis. The design values of load effects shall not exceed the design values of resistance for the relevant ultimate limit states.

12.4.3.1 *Design flexural resistance*

The design flexural resistance calculation shall take the following provisions into consideration:

a) The design bending resistance, M_d of any cross section should be in accordance with Annex C, where the yield stress of the steel sheeting should be taken as f_{yp};

b) The effect of local buckling of compressed parts of the sheeting should be considered by using effective widths not exceeding twice the limiting values of Class-1 steel webs as discussed in as per good practice [C-6B(3)];

c) For the effective area A_p of the steel sheeting, the width of embossments and indentations in the sheet should be neglected unless tests infer that a larger area is effective;

d) The sagging bending resistance of a cross-section should be calculated from the equilibrium of stress distribution as shown in **C-4**;

e) In hogging bending regions, the contribution of steel sheeting shall be taken into account only where the sheet is continuous. The redistribution of moments that can occur between support and mid-span sections shall not be considered. If the contribution of the steel sheeting is neglected, the hogging bending resistance of a cross-section should be calculated as reinforced concrete for the stress distribution, as shown in **C-4.3**; and

f) In the case of partial shear connection, the sagging design bending resistance, M_d, shall be calculated as per **C-5**.

12.5 Shear Resistance of Composite Slab

12.5.1 *Punching Shear*

The punching shear resistance of a composite slab should be calculated as per good practice [C-6B(2)], where the critical perimeter is as shown in Fig. 17.

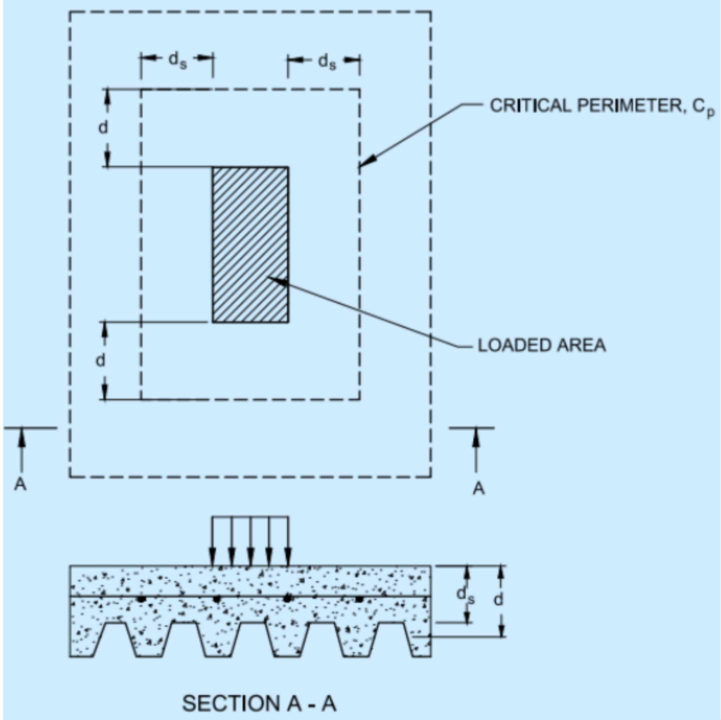

FIG. 17 PUNCHING PERIMETER IN A PROFILED COMPOSITE SLAB

12.5.2 *Resistance to Shear*

The vertical shear resistance V_{dvd} of composite slab over a width equal to the distance between centres of ribs and the effective depth, which depends on the effective depth of the cross section to the centroid of the tensile reinforcement, should be in accordance with as per good practice [C-6B(2)].

The sheeting may be considered as the tensile reinforcement, provided that it is fully anchored beyond the section considered. For heavily loaded slabs, additional reinforcement may be required at the support when the profiled steel sheeting is discontinuous and has only limited anchorage.

In the case of partial shear connection, the shear capacity may be governed by the interface shear strength between steel decking and concrete, as presented in Annex C.

12.6 Serviceability Limit State

12.6.1 *Design against Cracking*

The crack width is calculated at the top surface in the hogging moment region using standard methods prescribed for reinforced concrete in as per good practice [C-6B(2)]. Crack width should not exceed 0.3 mm. The provision of 0.4 percent steel at the top of the slab will normally avoid cracking problems in propped construction. The provision of 0.2 percent of steel is normally sufficient for the same in un-propped construction.

If the environment is corrosive, it is advisable to design the slab as continuous at supports and take advantage of steel provided for negative bending moment resistance and for minimizing cracking during service loads.

12.6.2 *Deflection Limits*

As per good practice [C-6B(2)] gives a stringent deflection limitation of span/350 or 20 mm whichever is less, which may be unrealistic for un-propped construction. The span to depth ratio in the range of 25 to 35 for the composite condition is recommended for the simply supported slabs and the continuous slabs. The deflection of the composite slabs is influenced by the slip between sheeting and concrete. Testing is the best method to estimate the actual deflection for the conditions adopted.

12.6.3 *Fire Resistance*

The fire resistance is based on (a) thermal insulation criterion concerned with limiting the transmission of heat by conduction and (b) integrity criteria concerned with preventing the spread of flames and hot gases to nearby compartments. These are met by specifying the adequate thickness of insulation below the metal decking. When the metal decking is used as a permanent shuttering, the fire resistance of the slab shall be considered as per as per good practice [C-6B(2)].

13 COMPOSITE COLUMNS

13.1 General

13.1.1 This section applies to various forms of steel-concrete composite columns, including fully or partly encased steel columns and concrete in-filled rectangular or circular steel tubes, provided:

a) The columns or compression members consist of structural steel with grade conforming to the accepted standard [C-6B(4)] and normal weight concrete of strength M20 to M60.

b) This clause applies to isolated columns or compression members in framed structures where the other structural members are either composite or steel members.

c) The steel contribution ratio δ (Table 12) should fulfill the criteria:

$$0.2 \leq \delta \leq 0.9$$

d) Further:

   1) The influence of local buckling of the structural steel section on the resistance of the composite section as a whole shall be considered in the design; and

2) The effects of local buckling may be neglected for a steel section fully encased in accordance with **13.2**, and for other types of cross-section, the maximum width to thickness ratio given in as per good practice [C-6B(3)] shall not be exceeded.

13.1.2 *Types of Composite Columns*

Composite columns can be of two types:

a) Encased where concrete encases the steel section (*see* Fig. 18); and

b) In-filled where concrete fills rectangular or circular steel tube (*see* Fig. 19).

13.2 Details for Composite Action

In composite columns with fully encased steel sections, concrete cover to structural steel sections shall be at least 40 mm or one-sixth of the breadth *b* of the flange, over steel section. The concrete shall be adequately held by steel reinforcements and stirrups all around. The steel section shall be unpainted to ensure bond and friction between steel and concrete, but cleaned to ensure protection against corrosion and spalling of concrete. The cover to steel reinforcement should be in accordance with as per good practice [C-6B(2)].

Shear transfer between steel-concrete interfaces is ensured basically through bond for which calculated shear stress at interface shall be limited in accordance with Table 15, beyond which mechanical shear connectors are to be provided.

13.3 Members Under Axial Compression

Standard composite sections used as columns are as shown at Fig. 18 and Fig. 19.

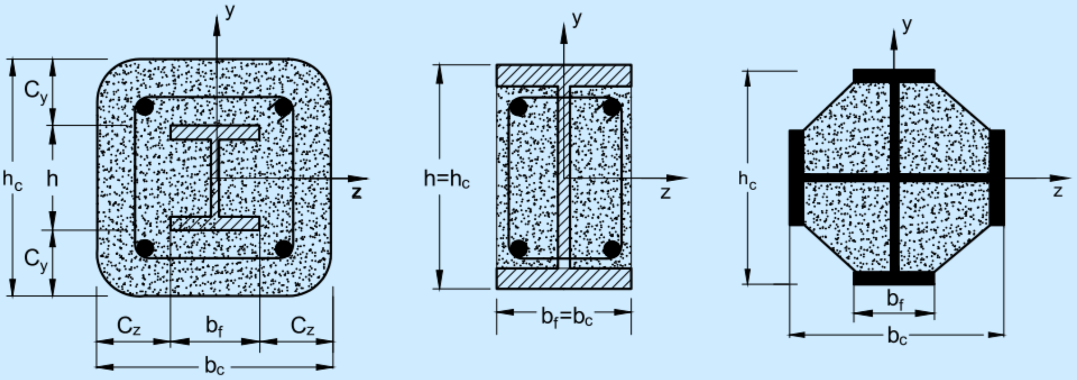

FIG. 18 FULLY AND PARTIALLY CONCRETE ENCASED COLUMNS

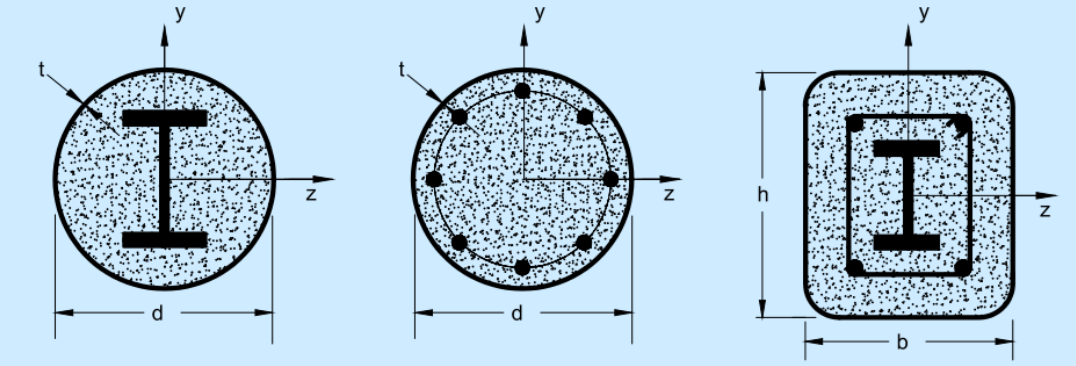

FIG. 19 CONCRETE IN-FILLED COLUMNS

13.3.1 *General Design Philosophy*

To ensure structural stability of a compression member, second-order effects like residual stresses, geometrical imperfections, local instability, cracking of concrete, creep/shrinkage of concrete, yielding of structural steel and reinforcement etc. shall be considered. While designing the compression members, including design for the above effects, the following shall be taken into account:

a) The above effects shall be considered in any direction in which failure might occur if they affect the structural stability significantly;

b) Internal forces shall be determined by any of the analysis methods discussed in **6**;

c) Full composite action between steel and concrete shall be considered up to failure; and

d) Effects of creep and shrinkage shall be considered if they are likely to reduce the structural stability significantly. For simplification, creep and shrinkage effects may be ignored if the increase in the first-order bending moments due to creep deformations from permanent loads is not greater than 10 percent of first-order bending moments due to total design loads.

13.3.2 *Design Guidelines*

The simplified design provisions given in the following sections is applicable for composite members that are doubly symmetrical and uniform in cross-section throughout the length of the member. This method is not applicable to members consisting of two or more unconnected sections. Further, the composite member should conform to the following conditions.

a) The non-dimensional slenderness λ shall not be greater than 2.

b) For a fully encased steel section (Fig. 18), the maximum thickness of concrete cover that may be used in the strength calculation is limited to:

$$c_z\,(Max) = 0.4\,b_f$$

$$c_y\,(Max) = 0.3\,h$$

c) The longitudinal steel reinforcement that may be used in the calculation should not exceed 6 percent of the concrete area; and

d) The ratio of the cross-section's depth h_c to width b_c, (*see* Fig. 18), should be within limits ($0.2 \leq h_c/b_c \leq 5.0$)

13.4 Local Buckling of Steel Sections

13.4.1 To prevent premature local buckling of structural steel components in partly encased steel section and concrete filled steel sections (Fig. 18 and Fig. 19), the width to thickness ratio of individual elements of the steel sections in compression must satisfy the following limits:

$\frac{d}{t} \leq 88\varepsilon^2$	for concrete-filled circular tubular sections
$\frac{h}{t} \leq 50\varepsilon$	for concrete-filled rectangular tubular sections
$b_f/t_f \leq 43\varepsilon$	for partially encased I sections

where

$\varepsilon = \sqrt{\frac{250}{f_y}}$ and f_y is the yield strength of the steel section, in MPa.

13.4.2 For fully encased steel sections, the above local buckling check is not required. However, the concrete cover to the flange of a fully encased steel section should not be less than 40 mm, nor less than one-sixth of the breadth, b_f, of the flange.

13.4.3 Design of concrete-filled rectangular tubular sections where *h/t* ratios exceed the local buckling limits for semi-compact sections should be verified by tests.

13.4.4 The cover to reinforcement should be in accordance with as per good practice [C-6B(2)].

13.4.5 The steel section shall not be painted to ensure friction between steel and concrete but cleaned at the abutting surface to ensure protection against corrosion and spalling of concrete.

13.5 Design Compressive Resistance of Short Composite Columns

13.5.1 A column is termed as a 'short column' when one of the following conditions is satisfied.

a) its non-dimensional slenderness ratio $\lambda \leq 0.2$; and

b) If the actual design compressive force on the composite column, P, is less than 0.1 P_{cr}.

where

$$\lambda = \sqrt{\frac{P_{\mathrm{n}}}{P_{\mathrm{cr}}}}$$

P_{cr} = the elastic buckling load of the column = $\frac{\pi^2 (EI)_{\mathrm{e}}}{L^2}$;

$(EI)_{\mathrm{e}}$ = effective elastic flexural stiffness of the composite column (13.5.2); and

L = the effective length of the column, which may be conservatively taken as the overall length L for an isolated non-sway composite column.

The design compressive strength P_{n} of short columns of plastic and compact sections may be evaluated using the design strength of the material with appropriate partial safety factors. The most common column sections are bi-symmetric. The design compressive strength of short bi-symmetric columns is evaluated using equations given in **D-2**.

NOTE — While providing spiral ties it must be designed as per of [C-6B(2)], and the ratio of the volume of helical reinforcement to the volume of the core is not less than 0.36 $(A_{\mathrm{g}}/A_{\mathrm{co}}-1)f_{\mathrm{ck}}/f_{\mathrm{yk}}$.

(Where, A_{g} = Gross area of section; A_{co} = Area of core of the confined core of column measured to the outer diameter of the helix).

13.5.2 *Effective Elastic Flexural Stiffness*:

a) *Short Term Loading* — The effective elastic flexural stiffness, $(EI)_{\mathrm{e}}$, is obtained by adding up the flexural stiffness of the individual components of the cross-section:

$$(EI)_{\mathrm{e}} = E_{\mathrm{s}} I_{\mathrm{s}} + 0.6\, E_{\mathrm{cm}} I_{\mathrm{c}} + E_{\mathrm{st}} I_{\mathrm{st}}$$

where

E_{s} and E_{st} = modulus of elasticity of the structural steel section and the reinforcement, respectively; and

E_{cm} = secant modulus of the concrete.

b) *Long Term Loading* — In slender columns ($\lambda > 0.2$), the effect of long-term loading should be considered.

$$(EI)_{\mathrm{e}} = E_{\mathrm{s}} I_{\mathrm{s}} + 0.6 E_{\mathrm{ceff}} I_{\mathrm{c}} + E_{\mathrm{st}} I_{\mathrm{st}}$$

$$E_{\mathrm{ceff}} = E_{\mathrm{cm}} \frac{1}{1 + \left(\frac{P_{\mathrm{G,E_d}}}{P_{\mathrm{E_d}}}\right) \varphi_{\mathrm{t}}}$$

where

φ_{t} = creep coefficient according to [C-6B(2)]

$P_{\mathrm{E_d}}$ = Total design axial load

$P_{\mathrm{G,E_d}}$ = Part of the *axial load* $P_{\mathrm{E_d}}$ that is caused due to the permanent gravity loads

If the eccentricity *'e'* of loading is more than twice the cross-section dimension *'D'* ($e > 2D$), the effect on the bending moment distribution caused by increased deflections due to creep and shrinkage of concrete will be very small and may be neglected. The effect of long-term loading need not be considered if the non-dimensional slenderness (λ) of the composite column is less than the limiting values given in Table 12.

Table 12 Limiting Values of λ or Long Term Loading

(*Clause* 13.1 *and* 13.5.2)

Sl No.	Cross-sections	Braced Non-sway Systems	Un-braced and/or Sway System
(1)	(2)	(3)	(4)
i)	Concrete encased cross-section	0.8	0.5
ii)	Concrete filled cross-section	$\frac{0.8}{1-\delta}$	$\frac{0.5}{1-\delta}$

NOTE — δ is the steel contribution ratio defined as $\delta = \frac{A_s.f_y}{P_d \gamma_{mo}}$.

P_d is defined in **D-2**.

When λ exceeds the limits prescribed above and $e/D < 2$, the effect of creep and shrinkage of concrete should be considered by adopting the modulus of elasticity of concrete E_{cs} instead of E_{cm} where E_{cs} is defined as follows:

$$E_{cs} = 0.75E_{cm}\left[1 - \frac{0.5P_{dd}}{P}\right]$$

where

P =the applied factored axial load; and

P_{dd} =the part of the factored load permanently acting on the column.

The effect of long-term loading may be ignored for concrete filled tubular sections with $\lambda \leq 2.0$ provided that $\delta > 0.6$ for braced (non-sway) columns and $\delta > 0.75$ for unbraced (sway) columns.

13.6 Long Members Subjected to Axial Compression

The non-sway composite columns need not be checked for buckling if any one of the following conditions is satisfied:

a) $P < 0.1P_{cr}$ where P is the axial force in the column, and P_{cr} is the elastic buckling load of the column, defined in **13.5.1**.

b) Non-dimensional slenderness $\lambda < 0.2$.

For columns not satisfying the above conditions, safety against buckling strength shall be checked about the corresponding axis. The following equation needs to be satisfied for buckling load:

$$P \leq \chi \cdot P_d$$

where

P = the applied factored axial load;

P_d = is the design plastic resistance to compression (**D-2**);

$\chi = \frac{1}{\phi + \sqrt{\phi^2 - \lambda^2}}$ = is the stability reduction factor;

$\phi = 0.5[1 + \alpha(\lambda - 0.2) + \lambda^2]$;

λ = Non-dimensional slenderness ratio;

α = A value that represents initial imperfections and residual stresses which is based on the buckling curve to be adopted, which is further dependent on the type of section and the axis of bending as given below (*see* Table 13):

Curve *a* = for concrete-filled tubular sections with reinforcement percentage less than 3 percent of gross cross section area and buckling about both axes.

Curve b = for fully or partially concrete-encased I-sections buckling about the strong axis (z-z axis) of the steel sections and for concrete-filled tubular sections with steel reinforcement percentage more than 3 percent of gross cross section area and buckling about both axes or concrete filled tubular section with the addition of I section at the core and buckling about both axes.

Curve c = for fully and partially concrete-encased I-sections buckling about the weak axis (y-y axis) of the steel sections.

Table 13 Imperfection Factor α for the Buckling Curves

(*Clause* 13.6)

Sl No.	Buckling Class	a_0	a	b	c	d
(1)	(2)	(3)	(4)	(5)	(6)	(7)
i)	α	0.13	0.21	0.34	0.49	0.76

13.7 Members Subjected to Combined Compression and Bending

When the bending moment in the section is zero (that is, M = 0), the design compressive strength is as given in **13.5**. Similarly, the plastic moment of resistance of a column at zero compression load is as given **D-3**. The equations for evaluating the design bending resistance of symmetric column sections are given in **D-4**.

13.7.1 *Bending Resistance under High Shear*

While determining the plastic resistance when the simultaneous shear force is high at the section as given below, the bending resistance shall be reduced as given below:

If the shear force V on the steel section exceeds 60 percent of the design shear resistance V_d of the steel (**8.3.6.1**), the influence of the transverse shear on the resistance in combined bending and compression shall be taken into account by a reduced design steel strength $(1 - \beta) f_y / \gamma_{m0}$ in the shear area A_v (β is determined as per **8.3.6.2**).

a) Unless a more accurate analysis is used, the design shear action, V_d, may be distributed into (V_s, acting on the structural steel) and (V_c, acting on the reinforced concrete section) as:

$$V_s = V \frac{M_{ds}}{M_d}$$

$$V_c = V - V_s$$

where

M_{ds} = design moment of resistance of steel section alone;

M = design moment of resistance of the entire composite section; and

V_d = may be assumed to be resisted by steel sections alone as a simplifying approximation.

13.7.2 *Second Order Effects on Bending Moment*

If neither of the two conditions (a) and (b) for short compression members in **13.5.1** is satisfied, then the second-order effects on first-order analysis moment shall be considered by modifying the maximum first-order bending moment (moment obtained linear elastic analysis), $M_{\max}$, with an amplification factor k, which is defined as:

$$k = \frac{C_\mathrm{m}}{1 - \frac{P}{P_\mathrm{cr}}} \geq 1.0$$

where

P = the applied factored axial load;

P_{cr} = elastic critical load for the relevant axis and corresponding to a modified effective flexural stiffness given by $(EI)_e$ as given in **13.5.2** and the effective length of the column is taken as per [C-6B(3)];

C_m = equivalent moment factor given in Table 14 to account for non-uniform bending moment over the length of the member; and

ψ = the ratio of moments at the ends of the laterally unsupported members.

13.8 Members Subjected to Axial Force and Uniaxial Bending

13.8.1 While checking a section for combined axial force and bending moment, first, it should be ensured that the section is safe against an axial force acting alone, considering buckling along each principal axis. The resistance of the section shall then be checked for combined axial compression and uniaxial bending moment, as described below:

The design against combined bending and axial compression are adequate when the following condition is satisfied:

$$M'_\mathrm{d} = \alpha_\mathrm{m}\mu_\mathrm{d}M_\mathrm{d}$$

where

α_m = reduction coefficient based on steel yield strength;

= 0.9 for $250 \geq f_y \leq 400$ MPa;

= 0.8 for $f_y > 400$ MPa;

M'_d = design bending moment, which is to be amplified to account for the second-order effects as discussed in **13.7.2**, when the column is not short; and

M_d = Design bending resistance of the section about the bending axis evaluated as in **D-3**.

The moment resistance reduction ratio μ_d for a long composite column under combined compression and uniaxial bending shall be evaluated as follows:

$$\mu_\mathrm{d} = \frac{(\chi - \chi_\mathrm{d})}{(1-\chi_\mathrm{c})\chi} \quad \text{when} \quad \chi_\mathrm{d} \geq \chi_\mathrm{c} \text{ and}$$

$$\mu_\mathrm{d} = 1 - \frac{(1-\chi)\chi_\mathrm{d}}{(1-\chi_\mathrm{c})\chi} \quad \text{when} \quad \chi_\mathrm{d} < \chi_\mathrm{c}$$

χ_c = Axial resistance ratio to the concrete P_c/P_d;

χ_d = Design axial resistance ratio to the concrete P/P_d;

χ = reduction factor due to column buckling as per good pratice [C-6B(3)];

P_c = axial compressive strength of concrete;

= $A_\mathrm{c}\frac{\alpha_\mathrm{cc.}}{\gamma_\mathrm{c}}.\eta.\lambda.f_\mathrm{ck}$; and

P_d = *see* **D-2**.

13.8.2 *Members Subjected to Axial Force and Bi-axial Bending*

Members subjected to combined axial compression and biaxial bending shall satisfy the following interaction relationships equations:

$$\frac{M_z}{\mu_{dz} M_{dz}} + \frac{M_y}{\mu_{dy} M_{dy}} \le 1$$

$$\frac{M_z}{\mu_{dz} M_{dz}} \le \alpha_{mz}$$

$$\frac{M_y}{\mu_{dy} M_{dy}} \le \alpha_{my}$$

where

μ_{dz} and μ_{dy} = moment resistance reduction factors in z and y directions, respectively. (*see* **13.8**)

$\alpha_{mz} = \alpha_{my} = \alpha_m$ (*see* **13.8**)

Table 14 Equivalent Uniform Moment Factor

(*Clause* 13.7.2)

Bending Moment Diagram (1)	**Range** (2)		***C*** C_{my}, C_{mz}, C_{mLT}	
			Uniform Loading (3)	Concentrated Load (4)
	$-1 \le \psi \le 1$		$0.6 + 0.4\,\psi \ge 0.4$	
	$0 \le \alpha_s \le 1$	$-1 \le \psi \le 1$	$0.2 + 0.8\,\alpha_s \ge 0.4$	$0.2 + 0.8\,\alpha_s \ge 0.4$
	$-1 \le \alpha_s \le 0$	$0 \le \psi \le 1$	$0.1 \quad - 0.8\,\alpha_s \ge 0.4$	$-0.8\,\alpha_s \ge 0.4$
		$-1 \le \psi \le 0$	$0.1(1-\psi) - 0.8\,\alpha_s \ge 0.4$	$0.2(-\psi) - 0.8\,\alpha_s \ge 0.4$
	$0 \le \alpha_h \le 1$	$-1 \le \psi \le 1$	$0.95 - 0.05\,\alpha_h$	$0.90 + 0.10\,\alpha_h$
	$-1 \le \alpha_h \le 0$	$0 \le \psi \le 1$	$0.95 + 0.05\,\alpha_h$	$0.90 + 0.10\,\alpha_h$
		$-1 \le \psi \le 0$	$0.95 + 0.05\,\alpha_h\,(1 + 2\,\psi)$	$0.90 + 0.1\alpha_h\,(1 + 2\,\psi)$
For members with sway buckling mode, the equivalent uniform moment factor $C_{my} = C_{mz} = 0.9$.

13.9 Mechanical Shear Connection and Load Introduction

Proper sharing of loads between the steel section and concrete of composite columns should be ensured at points of load introduction due to load and moment reactions coming from members connected to the ends of the column and also for axial loads applied anywhere within the length of the column, considering the shear resistance at the interface between steel and concrete.

Where composite columns and compression members are subjected to significant transverse shear, for example, by local transverse loads and by end moments, the provision shall be made for the transfer of the corresponding local longitudinal shear stress at the interface between steel and concrete. For axially loaded columns and compression members, longitudinal shear outside the region of load introduction need not be considered.

13.9.1 *Load Introduction*

Shear connectors should be provided at regions of load introduction and at regions with change in cross section, if the design shear resistance at the concrete-steel interface, τ, (Table 15) is exceeded. The shear forces should be determined from the change of sectional forces of the steel or reinforced concrete section within the introduction length. If the loads are introduced into the concrete cross section only, the values resulting from an elastic analysis considering creep and shrinkage should be taken into account. Otherwise, the forces at the interface should be determined by elastic theory or plastic theory to determine the more severe case. In the absence of any accurate method, the introduction length should not exceed $2d$ or $L/3$, where d is the minimum transverse dimension of the column and L is the column length.

Table 15 Design Shear Strength (τ)

(*Clauses* 13.2, 13.9.1 *and* 13.9.3)

Sl No.	Type of Cross-section	Design Shear Strength τ (N/mm^2)
(1)	(2)	(3)
i)	Completely concrete-encased steel sections	0.30
ii)	Concrete filled circular hollow sections	0.55
iii)	Concrete filled rectangular hollow sections	0.40
iv)	Flanges of partially encased sections	0.20
v)	Webs of partially encased columns	0.00

Due to the action of creep and shrinkage, no shear connection is required for composite columns or compression members if the load application is by endplate, where the full interface between steel and concrete is permanently under compression. Otherwise, the load application/introduction should be verified as given below:

a) If the cross-section is partially loaded, as shown in Fig. 20 (a), the loads may be distributed with a ratio of 1 : 2.5 over the thickness, t_e of the endplate. The concrete stresses should then be limited in the area of effective load introduction.

b) For concrete-filled circular hollow section or square hollow section, under partial loading as shown in Fig. 20(b), for example, by gusset plates or by stiffeners, the local design strength of concrete σ_c under the gusset or stiffener resulting from the sectional forces of the concrete section shall be determined as:

$$\sigma_c = \frac{\alpha_{cc} f_{ck}}{\gamma_c}\left[1 + \eta_0 \frac{t}{d} \frac{f_y}{\alpha_{cc} f_{ck}}\right]\sqrt{\frac{A_c}{A_1}} \leq \frac{A_c.\, \alpha_{cc} f_{ck}.}{A_1.\, \gamma_c};\ \leq \frac{f_y}{\gamma_{m0}}$$

where

$A_c/A_1 \leq 20$

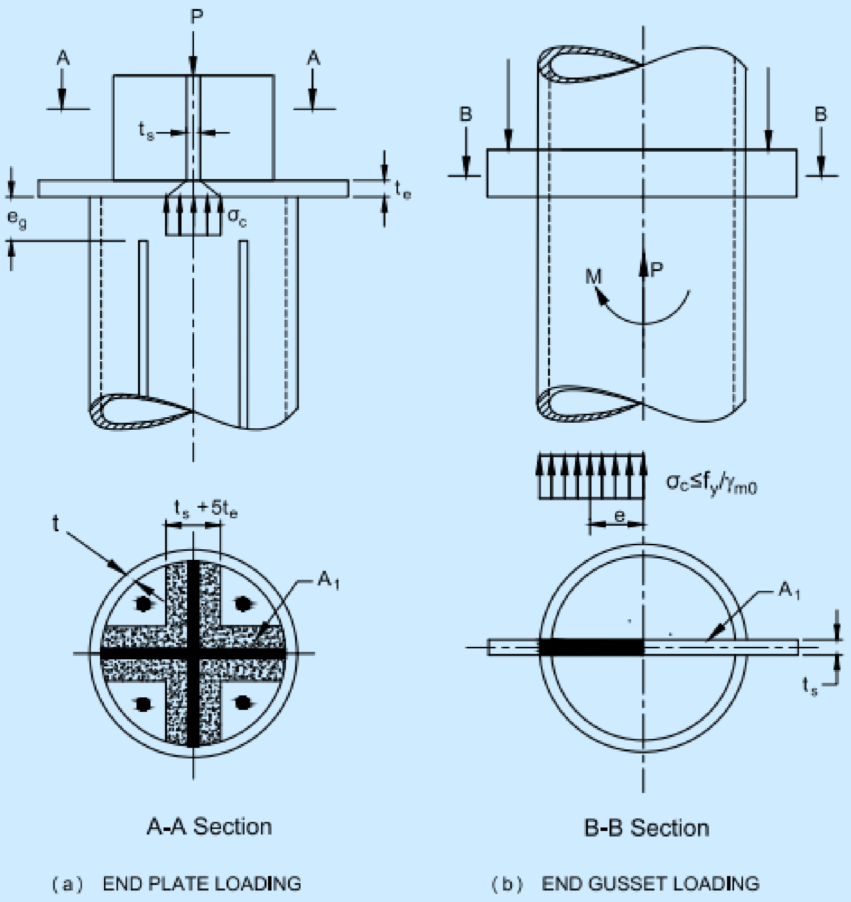
t = is the wall thickness of the steel tube;

d = diameter of the tube or width of the square section;

A_c = is the cross sectional area of the concrete section of the column;

A_1 = is the loaded area under the gusset plate (*see* Fig. 20); and

η_0 = 4.9 for circular steel tubes and 3.5 for square sections.



(a) END PLATE LOADING (b) END GUSSET LOADING

FIG. 20 PARTIALLY LOADED CIRCULAR CONCRETE FILLED HOLLOW SECTION

c) For concrete-filled circular hollow sections, longitudinal reinforcements may be taken into account while determining the resistance of the composite column, even if the reinforcement is not directly connected to the endplate, provided that the gap [Fig. 20(a)] between the end of reinforcement and the surface of the endplate does not exceed 30mm.

13.9.2 *Shear connection*

When a mechanical connection is introduced in the form of stud connectors to the web of a fully or partially concrete-encased steel I-section, an account may be taken of the frictional forces that develop due to the restraint in lateral expansion of the concrete by the adjacent steel flanges. This resistance is assumed to be equal to $\mu.Q_u/2$ on each flange and each horizontal row of studs, as shown in Fig. 21 and may be added to the calculated resistance of the shear connectors. μ is the relevant coefficient of friction and be taken as 0.5. Q_u is the resistance of a single stud as per **11.2**.

The clear distance between the flanges should not exceed the values given in Fig. 21 to ensure the development of the frictional forces between concrete and steel flanges.

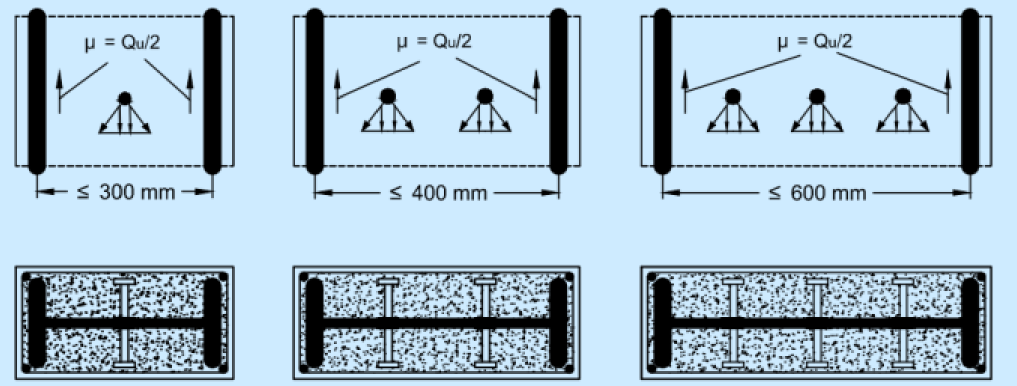


FIG. 21 ADDITIONAL FRICTIONAL FORCES IN COMPOSITE COLUMNS BY USE OF HEADED STUDS

13.9.3 *Longitudinal Shear Outside Area of Load Introduction*

a) Outside the area of load introduction, longitudinal shear at the interface between concrete and steel should be verified where it is caused by transverse loads and /or end moments. Shear connectors should be provided based on the distribution of the design value of longitudinal shear, where this exceeds the design shear resistance τ. In the absence of a more accurate method, elastic analysis, considering long-term effects and cracking of the concrete, may be used to determine the longitudinal shear at the interface. Provided that the surface of the steel section, in contact with the concrete, is unpainted and free from oil, grease, and loose scale or rust, the values given in Table 15 may be assumed for τ. The value of τ given in Table 15 for fully concrete-encased steel sections applies to sections with a minimum concrete cover of 40 mm. For greater concrete cover and adequate reinforcement, higher values of τ may be used. Unless verified by tests, for completely encased sections, the increased value β_c. τ may be used, with β_c given by:

$$\beta_c = 1 + 0.02\, c_z \left[1 - \frac{c_{z,\min}}{c_z}\right] \leq 2.5$$

where

c_z = is the wall thickness of the steel tube; and

$c_{z,\min}$ = diameter of the tube or width of the square section.

b) Unless otherwise verified, for partially encased I-sections with transverse shear due to bending about the weak axis caused by lateral loading or end moments, shear connectors should always be provided. If the resistance of the structural steel section alone against transverse shear is not sufficient to take care of the total transverse shear on the composite section, then the required transverse reinforcement for the shear force, V_c according to **12.5.2**, should be welded to the web of the steel section or should pass through the web of the steel section.

13.10 Shear Check

The factored shear force in the compression members should be less than the design shear strength of the member, which is the sum total of the shear resistance given by the concrete section along with steel reinforcements as per good practice [C-6B(2)] and the shear resistance given by the steel section as per **8.3.6**. The shear force shall be distributed between the steel section and the concrete section in accordance with **13.9**.

14 CONSTRUCTION AND ERECTION

14.1 Fabrication and Inspection Procedure for Structural Steel

Fabrication and erection of steel sections and components, as and where situated in a composite structure would include fabrication procedures, both shop and site fabrications, along with fabrication tolerances, inspection, testing, handling, transportation, site storage, erection along with erection tolerances, etc.

Fabrication and erection specifications of all steel components of a composite structure shall refer to stipulations laid down in good practice [C-6B(3)].

15 FIRE RESISTANCE AND FIRE DESIGN

15.1 In closed structures, an accidental fire may lead to a rise in temperature under which failure of the material may take place unless a proper design and construction against fire is carried out. Open structures such as bridges are not generally vulnerable to failure under fire since the temperature does not go up to the level which may cause material damage. Also, in an open structure, the fire can be extinguished easily and quickly. Fire tests on open structures such as elevated parking lots and bridges have shown that the structure does not undergo any material damage due to reasons indicated above. However, all structures, including both closed and open ones, shall be protected from all possible accidental fires caused by different kinds of hazards.

Fire-resistant designs for open and closed structures at specialized locations, such as those in proximity to oil installations or pipelines carrying inflammable materials, etc as in the case of industrial buildings and structures, shall be done based on recommendations given in specialized literature. Also, adequate provisions may be made for firefighting equipment to access all parts of the structure as per Part F ‘Fire and Life Safety’ of this NBCS. After the occurrence of fire in a structure, it should be mandatory for the concerned authorities to have the structure inspected by competent experts in order to ascertain the condition of the structure before it can be declared safe for re-use.

In addition to the above, locations in any structural system that may be prone to accidental occurrence of fire, shall be adequately provided with basic fire protection methods as per specialist literature. These will include both active as well as passive fire protection.

15.2 Response to Fire

Steel is a good conductor of heat that experiences an almost uniform temperature increase over its entire volume. Concrete is a poor conductor of heat has a large temperature gradient within its volume. Due to this, the entire steel member gains the heat faster, whereas the surfaces of concrete exposed directly to heat experience high temperature, with the temperature dropping off drastically in the interior of the concrete mass.

Both steel and concrete exhibit a drastic reduction in strength with an increase in temperature above 400 °C. Due to this, the resistance of steel members tends to decrease drastically above 400 °C, whereas concrete at the surfaces exposed to high temperature tends to spall off due to high temperature gradient. The steel structure, if it does not fail under fire, regains its strength after the fire, the damage at the surface of the concrete is permanent due to chemical changes. The steel reinforcement in concrete is protected from loss of strength due to an increase in temperature by providing adequate concrete cover as per good practice [C-6B(2)]. Composite floor system deck sheeting is to be provided with fire protection.

However, literature shows that the minimum necessary fire resistance can be achieved by using the composite floor systems and the composite columns, without applying fire protection. Interaction of the steel beam and the concrete slab in the composite flooring leads to a higher critical temperature and higher fire resistance.

The requirements for fire resistance shall apply to steel elements of steel-concrete composite structure designed to exhibit a required fire resistant level as per the relevant specifications.

15.2.1 *Design Fire*

The design of a structure against fire load is dependent on the required fire resistant level (FRL), which is dependent on the function of the structure itself and the period of structural adequacy (PSA). These shall be calculated based on the stipulation laid down in as per good practice [C-6B(3)].

The response of steel elements of a composite structure against fire as laid down in as per good practice [C-6B(3)] shall be binding on all steel elements of the composite structures which are susceptible to rise in temperature during its design life. For all general buildings, an adequate fire protection methodology shall be adopted.

15.2.2 *Fire Protection Methodology*

Apart from the direct design of steel components against fire as required in as per good practice [C-6B(3)] (protected as well as unprotected section), other protective measures, (both active and passive), also may be adopted as recommended in literature as fire-resistant procedures.

For active fire resistance, provisions of fire locating and fighting measures like the smoke detectors, fire extinguishers inside a building along with accessory fire water supply, sprinkler system, etc, shall be made available at vantage points. The planning of the structure shall be made in such a way that it is accessible from all sides to fire extinguishing vehicles.

For passive fire resistance, protective paints and materials like intumescent paints, vermiculite boards etc, may be used on exposed steel surfaces, and their provision shall be made as per the required fire-resistant level and as per their properties and specification provided by the manufacturers. The design of protected sections shall be done as per the stipulations laid down in the relevant section of as per good practice [C-6B(3)]. Detailed design against the fire may be based on provisions of other composite codes and specialized literature.

15.2.3 *Fire Resistance of Composite Slabs*

The fire resistance is assumed based on the following two criteria:

a) Thermal insulation criterion, concerned with limiting the transmission of heat by conduction; and

b) Integrity criterion is concerned with preventing the flames and hot gases from nearby compartments. It is met by specifying an adequate thickness of insulation.

16 TESTING METHODS

For testing methods, Annex E may be referred.

ANNEX A

(*Clause* 4)

SYMBOLS

A-1 The letter symbols and notations given below apply to the provision of this section:

a	Span length of the slab transverse to the steel beams
A_s	Area of structural steel cross section
A_{sl}	Area of structural steel cross section in tension
A_c	Gross area of concrete
A_{co}	Equivalent area of the cracked composite beam section
A_{ec}	Area of concrete effective in compression
A_p	Effective cross-sectional area of profile steel sheeting
A_{st}	Area of steel reinforcements
A_f	Area of each flange of steel section
A_e	Effective cross sectional area
A_{sv}	Area of shear resistance
B	Centre to centre distance between beams and is equal to the transverse span of inner beam
b_c	Width of concrete encasement
b_p	Distance between the centres of adjacent ribs or one wave length of a profile deck
b_e	Effective width of the flange between pair of bolts
b_{eff}	Effective width of concrete flange
b_f	Width of the structural steel flange
D	Overall depth of girder/diameter of the steel cross section.
d	Depth of the web, Nominal diameter of bolts/rivets/studs.
d_2	Twice the clear distance from the compression flange of angles, plates, or tongue plates to the neutral axis
d_c	Vertical distance between the centroid of concrete slab and centroid of steel beam
d_s	Overall depth of the concrete slab
d_o	Nominal diameter of the pipe column or the dimensions of the column in the direction of depth of the base plate
d_p	Depth of profiled sheet deck
d_{sp}	Overall depth of the profiled sheet deck and concrete slab
e	Distance between the C.G. axis of the profiled steel sheeting and the extreme tension fiber of the composite slab
e_p	Distance between the plastic neutral axis and the extreme tension fiber of the composite slab
$E_{c,l}$	Modulus of elasticity of lightweight concrete
E_s	Modulus of elasticity of structural steel
E_{cm}	Secant Modulus of elasticity of concrete
E_{st}	Modulus of elasticity of steel reinforcements
F_f	Axial capacity of a single flange
F_{sr}	Axial capacity of reinforcing steel

F_{cc}	Compressive force in the concrete above the neutral axis
F_{sc}	Compressive force in the steel section above the neutral axis
F_{st}	Tensile force in the steel section below the neutral axis
F_{w}	Design capacity of the web in bearing
f	Actual normal stress range for the detail category
f_{c}	Actual axial compressive stress in concrete at service load
$f_{ctm, l}$	Tensile strength of lightweight concrete
f_{ck}	Characteristic compressive cube strength of concrete at 28 days
$f_{ctk(0.05)}$	Characteristic axial tensile strength of concrete based on 5 percent fractile
f_{ctm}	Mean axial tensile strength of concrete
f_{f}	Fatigue stress range corresponding to 5×10^{6} cycles of loading
f_{fd}	Design fatigue normal stress range
f_{feq}	Equivalent constant amplitude stress
$f_{f\,max}$	Highest normal stress range
f_{fn}	Normal fatigue stress range
f_{o}	Proof stress
f_{yk}	Characteristic yield strength of reinforcement
f_{yf}, f_{yw}	Yield strength of flange and web, respectively
f_{u}	Characteristic ultimate tensile stress
f_{up}	Characteristic ultimate tensile stress of the profiled deck
f_{y}	Characteristic yield stress of structural steel
f_{yp}	Characteristic yield stress of profiled deck
h	Depth of the section/total depth of steel beam
H	Distance between top of concrete and bottom of bottom flange of steel beam
h_{s}	Distance between centroids of top and bottom flanges /nominal height of stud
h_{y}	Distance between shear centre of the two flanges of the cross section
I	Moment of inertia of the member about an axis perpendicular to the plane of the frame
I_{c}	Moment of inertia of concrete (assumed uncracked) about the axis of bending for column
I_{co}	Moment of inertia of the composite section
$I_{fc,y}$	Moment of Inertia of the compression flange about the minor axis of the steel beam
$I_{ft,y}$	Moment of Inertia of the tension flange about the minor axis of the steel beam
I_{s}	Moment of inertia of the steel section about the axis of bending for column
I_{st}	Moment of inertia of reinforcement about the axis of bending for column
I_{z}	Moment of inertia about the major axis
I_{ys}, I_{zs}	Second moment of area of steel section about the minor and major axis respectively
I_{ybf}	Moment of inertia of the bottom flange about the minor axis of the steel section
I_{zco}	Second moment of the equivalent area of the cracked composite beam section for major axis bending
k_{1}	Flexural stiffness of the steel web per unit length along the beam
k_{2}	Flexural stiffness of the cracked concrete or composite slab transverse to the spanning direction of steel beam

KL	Effective length of the member
KL/r	Appropriate, effective slenderness ratio of the section
KL/r_y	Effective slenderness ratio of the section about the minor axis
KL/r_z	Effective slenderness ratio of the section about the major axis
L	Actual span of composite beams
L_{bs}	Minimum bearing lengths of steel decking on the support
L_{bc}	Composite slab including the cast in place concrete
L_c	Effective span of the cantilever for overhang
L_o	Length between points of zero moments (inflection) in the span
L_s	Shear span
L_x	Distance of the maximum moment cross section under consideration to the support
M	Bending moment
M_v	Reduced bending moment due to effect of shear force
M_{cr}	Elastic critical moment corresponding to lateral torsional buckling
M_d	Design bending strength/design bending resistance under only bending moment
M'_d	Design bending resistance under combined bending and compression
M_{dp}	Design bending resistance of profiled steel sheeting
M_e	Elastic moment capacity of the section
M_f	Design plastic resistance of the flange alone for steel section
M_p	Plastic moment capacity of the section
M_y	Factored applied moments about the minor axis of the cross section
M_z	Factored applied moments about the major axis of the cross section
m	Modular ratio
m_{dl}	Modular ratio (long term)
m_{ll}	Modular ratio (short term)
N_{SC}	Number of stress cycles
P	Design axial force
P_{cr}	Elastic critical buckling load
P_p	Plastic resistance of encased steel column section or concrete filled rectangular or square column section
R_h	Flange stress reduction factor for hybrid section
r	Appropriate radius of gyration
r_y	Radius of gyration about the minor axis
r_z	Radius of gyration about the major axis
S	Spacing
S_l	Spacing of shear connectors for longitudinal shear due to flexural force
S_r	Spacing of shear connectors due to bending moment
t	Thickness of element/angle, time in minutes
t_f	Thickness of flange of steel section
t_p	Thickness of profiled deck sheet

t_w	Thickness of web of steel section,
V, V_v, V_L	Factored applied shear force
V_d	Design shear resistance
V_{dvd}	Vertical shear resistance
V_p	Plastic shear resistance under pure shear
V_{vd}	Design vertical shear resistance
W	Total equivalent load
X	Distance from the centre line of edge beam to the edge of slab
x_e	Depth of elastic neutral axis of the composite section from the centroid of steel section
x_u	Depth of neutral axis at limit state of flexure from top of the concrete
Z_e	Elastic section modulus
Z_p	Plastic section modulus
Z_{pc}, Z_{pcn}	Plastic section modulus of concrete about its own centroid and about the neutral axis of the composite section, respectively
Z_{pr}, Z_{prn}	Plastic section modulus of reinforcement about its own centroid and about the neutral axis of the composite section, respectively
Z_{ps}, Z_{psn}	Plastic section modulus of structural steel section about its own centroid and about the neutral axis of the composite section, respectively
y_g	Distance between the point of application of the load and shear centre of the cross section
α	Imperfection factor
α_c	Strength coefficient of concrete
δ	Steel contribution ratio
χ	Stress reduction factor due to buckling under compression
χ_m	Stress reduction factor, χ at f_{ym}
χ_m	Stress reduction factor to account for lateral torsional buckling of a beam
γ	Unit weight of steel
γ_c	Partial safety factor for material (concrete)
γ_f	Partial safety factor for load
γ_{m0}	Partial safety factor against yield stress and buckling (structural steel)
γ_{m1}	Partial safety factor against ultimate stress (structural steel)
γ_{mf}	Partial safety factor for the strength of bolt
γ_{fft}	Partial safety factor for fatigue load
γ_{mft}	Partial safety factor for fatigue strength
γ_{mv}	Partial safety factor against shear failure
γ_{mw}	Partial safety factor for the strength of the weld
γ_k	Partial safety factor for material (reinforcements)
ε	Yield stress ratio, $(250/f_y)$ 1/2
λ, λ_r	Non dimensional slenderness ratio = $\sqrt{f_y(KL/r)^2/\pi^2E} = \sqrt{f_y/f_{cr}} = \sqrt{P_y/P_{cr}}$
λ_e	Equivalent slenderness ratio
μ_s	Poisson's ratio of structural steel

μ_c	Correction factor
η_1, η_2	Strength coefficients
η_{10}, η_{20}	Strength coefficients
τ	Actual shear stress range for the detail category
τ_f	Fatigue shear stress range
τ_{fd}	Design fatigue shear stress range
$\tau_{f,max}$	Highest shear stress range
τ_{fn}	Fatigue shear stress range at N_{SC} cycle for the detail category

ANNEX B

(*Clauses* 8.1.1, 8.1.2, 8.3.5.2, 8.3.5.3 *and* 8.3.7)

BENDING RESISTANCE OF COMPOSITE BEAMS

The stress distribution and the methods of evaluation of the sagging and hogging bending resistances under full and partial shear interaction of composite beams are discussed in this Annex.

B-1 SAGGING MOMENT RESISTANCE OF COMPOSITE SECTION WITH PLASTIC OR COMPACT STRUCTURAL STEEL BEAMS

B-1.1 Sagging Bending Resistance with Full Shear Interaction

The equations for calculating the bending resistance of composite beams are presented in this section. It is assumed that sufficient shear connectors are provided between the structural steel and concrete to develop full shear with no-slip during the service load.

Initially, evaluating the resistance is based on parabolic stress block as per good practice [C-6B(2)], over the entire depth of concrete in compression is presented. This is theoretically more accurate than the rectangular stress block (maximum of 2-3 percent difference), but computationally more tedious, particularly when it comes to sections subjected to combined bending and compression.

Subsequently, equations based on rectangular stress block for concrete in compression is presented. This is assumed so that the calculations are simplified. This method is easy to use, particularly when the neutral axis is in or closer to compression flange of the steel section.

In both the above methods, the stress in the reinforcing steel in the concrete slab under compression is disregarded.

B-1.1.1 *Based on Parabolic Stress Block Satisfying Stress Strain Relationship*

Calculation of bending resistance is based on parabolic stress block, which is compatible with strain diagram. The design bending resistance depends on the location of the plastic neutral axis. Table 16 gives the various cases of design bending moments of a composite section depending upon the location of the plastic neutral axis as shown in Fig. 22, Fig. 23 and Fig. 24. For hybrid sections, appropriate yield strength in flanges and web shall be considered for calculation of the plastic moments.

NOTE — Notations used in the determination of plastic bending resistance

A_f = area of the top flange of steel beam of a composite section.

A_s = cross sectional area of structural steel beam of a composite section.

b_{eff} = effective width of concrete slab.

b_f = width of top flange of steel section.

d_s = overall depth of concrete slab.

d_c = vertical distance between centroids of concrete slabs and steel beam in a composite section.

t_f = average thickness of the top flange of the steel section.

t_w = thickness of the web of the steel section.

x_u = depth of neutral axis at ultimate limit state of flexure from top of concrete.

M_d = design bending resistance.

α_{cc} = 0.67.

γ_c = material safety factor for concrete .

= 1.50 (for basic and seismic combinations).

= 1.0 (for accidental combinations).

γ_{m0} = material safety factor for structural steel = 1.10

γ_k = material safety factor for reinforcing steel = 1.15

η = 1.0 [for $f_{ck} \leq 60$ MPa]

= $1.0 - (f_{ck} - 60) / 250$ [for $60 < f_{ck} \leq 110$ MPa]

λ = 0.8 [for $f_{ck} \leq 60$ MPa]

= $0.8 - (f_{ck} - 60) / 500$ [for $60 < f_{ck} \leq 110$ MPa]

B-1.2 Bending Moment with Partial Shear Interaction

B-1.2.1 Partial shear connection is applicable only in the case of plastic resistance of sections with plastic and compact classifications. Provisions for partial shear connection is applicable either for attaining economy without losing much in moment capacity of the composite section or in conditions where the number of shear connectors required for full shear interactions cannot be provided due to lack of space or increased spacing of shear connectors due to provision of lesser numbers of shear connectors than that needed for full composite action.
Degree of shear connection S_c is given as

$$S_c = \frac{n_p}{n_f} = \frac{F_{cp}}{F_{cf}} = \frac{M - M_{ds}}{M_d - M_{ds}}$$

where

n_p = Number of shear connectors provided for partial shear connection;

n_f = Number of shear connectors required for full shear connection;

F_{cp} = Capacity of shear connectors in partial shear connection with n_p numbers of connectors;

F_{cf} = Capacity of shear connectors in full shear connection with n_f numbers of connectors;

M = Required bending resistance of the section;

M_d = Design bending resistance of the composite section; and

M_{ds} = Design bending resistance of steel section alone.

B-1.2.2 To obtain required bending resistance M, the number of shear connectors required (assuming all connectors have equal capacity) is given as:

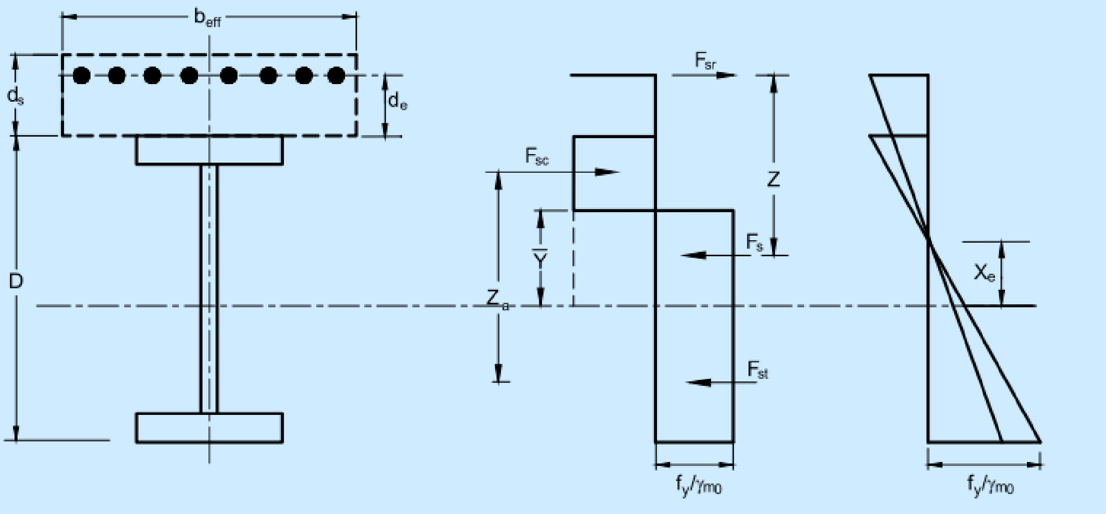
$$n_{\mathrm{p}} = n_{\mathrm{f}}\,\{(M - M_{\mathrm{ds}})/(M_{\mathrm{d}} - M_{\mathrm{ds}})\}$$

B-1.3 Sagging Bending Resistance of Composite Section with Non-Compact Structural Steel Beams

Since the compression flange of semi-compact steel sections buckle locally under compression on reaching yield stress f_y, the design resistance of the composite section consisting of semi-compact sections is evaluated using equations of compact sections as per **B-1**, wherein the effective width of elements of section like the compression flange is restricted to limiting value of that of the compact section.

B-2 MOMENT OF RESISTANCE OF COMPOSITE SECTION (NEGATIVE MOMENT-CONTINUOUS BEAMS)

Figure 28 shows stress distribution across a composite beam section subjected to hogging bending moment. Since the steel bottom flange is in compression section classification shall be done as per [C-6B(3)]. For classification of the web, the distance, $\bar{y}$, of the plastic neutral axis above the centroid of the area of the steel section shall first be found.



(a) Plastic and compact section (b) Semi-compact section

FIG. 28 STRESS DIAGRAM FOR HOGGING MOMENT REGION AT ULTIMATE MOMENT

B-2.1 Hogging Bending Resistance for Plastic and Compact Structural Steel Sections

The design tensile force in reinforcement is given as:

$$F_{\mathrm{sr}} = f_{\mathrm{yk}}.A_{\mathrm{st}}/\gamma_{\mathrm{k}}$$

where

γ_{k} = partial safety factor for reinforcing steel = 1.15;

f_{yk} = Characteristic yield strength of the reinforcing steel; and

A_{st} = the effective area of longitudinal reinforcement within the effective width b_{eff} of the beam

The plastic moment of resistance for plastic and compact structural steel section is given as:

$$M_{\mathrm{ds}} = \frac{Z_{\mathrm{p}} . f_{\mathrm{y}}}{\gamma_{\mathrm{m0}}}$$

where

Z_p is the plastic section modulus of the structural steel section and γ_{m0} is the material safety factor to be taken as 1.10. In the absence of any tensile reinforcements, the bending resistance of the section would be that of the structural steel section as given by M_{ds} above. To allow for reinforcements, it is assumed that the stress in a depth $\overline{y}$ changes from tension to compression for Plastic and compact section. The corresponding depth for a non-compact section is x_e. For plastic and compact sections, stress distribution $\overline{y}$ may be determined from

$$\overline{y}\, t_{\mathrm{w}} \frac{2 f_{\mathrm{y}}}{\gamma_{\mathrm{m0}}} = F_{\mathrm{s}}$$

The locations of the neutral axis and the bending resistance for the plastic and compact section are given in Table 18.

Table 18 Hogging Bending Resistance of Plastic and Compact Composite Section

(*Clause* B-2.1)

Case	Position of Plastic Neutral Axis	Value of $\overline{y}$	Moment Capacity M_{dh}
(1)	(2)	(3)	(4)
1	In Web	$\overline{y} \leq \frac{D}{2} - t_{\mathrm{f}}$	$M_{\mathrm{dh}} = M_{\mathrm{ds}} + F_{\mathrm{sr}} Z$
2	In Flange	$\frac{D}{2} \geq \overline{y} > \frac{D}{2} - t_{\mathrm{f}}$	$M_{\mathrm{dh}} = F_{\mathrm{b}} \frac{D}{2} + F_{\mathrm{sr}}\, d_{\mathrm{s}} - \frac{(F_{\mathrm{b}} - F_{\mathrm{sr}})^2}{F_{\mathrm{f}}} \frac{t_{\mathrm{f}}}{4}$

where

$Z = \frac{D}{2} + d_{\mathrm{s}} - \frac{\overline{y}}{2}$

F_{f} = Axial capacity of a single flange $= \frac{f_{\mathrm{y}} . A_{\mathrm{f}}}{\gamma_{\mathrm{m0}}}$

F_{b} = Axial capacity of steel section $= \frac{f_{\mathrm{y}} . A_{\mathrm{s}}}{\gamma_{\mathrm{m0}}}$

F_{sr} = Axial capacity of reinforcing steel $= \frac{f_{\mathrm{yk}} . A_{\mathrm{st}}}{\gamma_{\mathrm{k}}}$

A_{s} = area of structural steel cross section

A_{f} = area of top flange of structural steel cross section

A_{st} = area of reinforcing steel within the effective width of concrete flange

d_{s} – overall depth of the concrete slab

d_{e}= Effective depth of the slab

t_{f} = Average thickness of the top flange of the steel section

t_{w} = Thickness of the web of the steel section

NOTE — The web shall be classified as being in compression throughout.

B-2.2 Hogging Bending Resistance for Non-Compact Section

Where elastic analysis is used, creep is considered in the choice of modular ratio m (= E_s/E_{cm}). Here, at the section considered, the loading causes hogging bending moment $M_{e(s)}$ in the steel member alone and [$M_{e(c)}$] in the composite member.

The location of the elastic neutral axis of the composite semi-compact section [*see* Fig. 28(b)] is given as:

$$x_e(A_s + A_{st}) = A_{st}\left(\frac{D}{2} + d_s\right)$$

and the second moment of area of the composite section is:

$$I_{co} = I_s + A_s.x_e{}^2 + A_{st}\left(\frac{D}{2} + d_s - x_e\right)^2$$

Where, I_s is the second moment of area of the steel section alone.

The yield moment is mostly governed by the total stress in the steel bottom flange. The locations of the neutral axis and the moment of resistance for non-compact section is given in Table 19.

The bending moment [$M_{e(s)}$] causes no stress in the slab reinforcements. In propped construction, the tensile stress in the reinforcement may govern the design. It is given in the following equation:

$$\sigma_{sr} = \frac{\left(\frac{f_y}{\gamma_{m0}} - f_s\right)\left(\frac{D}{2} + d_s - x_e\right)}{\left(\frac{D}{2} + x_e\right)} \leq \frac{f_{yk}}{\gamma_k}$$

Table 19 Hogging Bending Resistance of Non-compact Composite Section

(*Clause* B-2.2)

Location of Neutral Axis	**Moment Capacity of Steel Section Alone [f_s] $\bar{y}$**	**Moment Capacity $M_{d(c)}$**
(1)	(2)	(3)
$x_e(A_s + A_{st}) = A_{st}\left(\frac{D}{2} + d_s\right)$	$f_s = M_{e(s)}.\frac{D/2}{I_s}$	$M_{d(c)} = M_{e(s)} + \frac{\left(\frac{f_y}{\gamma_{m0}} - f_s\right) I_{co}}{\left(\frac{D}{2} + x_e\right)}$

NOTE — The web shall be classified as being in compression throughout.

where

A_{st} = cross sectional area of reinforcements within the effective width of the concrete flange;

A_s = cross sectional area of steel beam of a composite section;

d_s = overall depth of the slab;

d_e = effective depth of the slab;

$M_{e(s)}$ = hogging moment in the steel section alone;

f_s = compressive stress in steel flange due to moment $M_{e(s)}$;

I_s = moment of inertia of the steel beam alone;

I_{co} = moment of inertia of the composite section;

t_f = average thickness of the top flange of the steel section; and

t_w = thickness of the web of steel section.

B-3 FLANGE STRESS REDUCTION FACTOR (R_h) FOR HYBRID SECTIONS

Flange stress reduction factor is applicable for hybrid sections using higher-grade steel flanges where the section is non-compact, or in other words, where the section reaches the plastic moment capacity. In such cases, design limiting stress for both compression and tension shall be modified by the reduction factor R_h and shall be taken as:

$$f_n = R_h \,.\, f_{yf} / \gamma_{m0}$$

where

R_h = $(D.f_{yw}) / (d.f_{yf}) \leq 1.0$;

f_{yf}, f_{yw} = the yield strength of the flange and web respectively; and

D, d = the distance of the extreme compression/tension flange and the corresponding extreme fiber of the web from the neutral axis of the composite section respectively.

For homogeneous grade steel sections, R_h shall be 1.0. The reduction factor shall not apply to compact or plastic sections because the effect of lower strength material in the web is accounted for in calculating the plastic moment as specified in B-1.1.

B-4 MOMENT OF RESISTANCE AGAINST LATERAL-TORSIONAL BUCKLING (CONSTRUCTION STAGE)

At the construction stage, before the concrete hardens, the structural steel beam strength may be dictated by the lateral buckling strength. This may be evaluated as per good practice [C-6B(3)].

Effect of lateral-torsional buckling on flexural strength need not be considered if $\lambda_{LT} \leq 0.4$.

B-4.1 Sagging Lateral Buckling Resistance of Structural Steel Beams

The design buckling resistance moment of a laterally unrestrained beam under un-propped condition during the construction stage shall be taken as:

$$M_d = \beta_b Zp \left(\frac{\chi_{LT} \, f_y}{\gamma_{m0}} \right)$$

where

$\chi_{LT} = \frac{1}{[\varphi_{LT} + (\varphi_{LT}^2 - \lambda_{LT}^2)^{\frac{1}{2}}]} \leq 1.0$ and

$\varphi_{LT} = 0.5[1 + \alpha_{LT}(\lambda - 0.2) + \lambda_{LT}^2]$ and

$\alpha_{LT} =$ As per Table 13

The non-dimensional slenderness ratio, λ_{LT}, is given by:

$$\lambda_{LT} = \sqrt{\frac{\beta_b Z_p f_y}{M_{cr}}} \leq \sqrt{\frac{1.2\, Z_e f_y}{M_{cr}}}$$

$$\lambda_{LT} = \sqrt{\frac{f_y}{f_{crb}}}$$

where

β_b = 1.0 for Plastic and Compact sections;

= Z_e / Z_p for semi-compact sections; and

M_{cr} = the elastic critical moment corresponding to lateral torsional buckling.

In the case of simply supported prismatic members with symmetric cross-section, the elastic critical moment, M_{cr}, can be determined as:

$$M_{\mathrm{cr}} = \sqrt{\left\{\left(\frac{\pi^2 EI_y}{(L_{\mathrm{LT}})^2}\right)\left[GI_t + \frac{\pi^2 EI_w}{(L_{\mathrm{LT}})^2}\right]\right\}} = \beta_{\mathrm{b}} Z_{\mathrm{p}} f_{\mathrm{crb}}$$

The maximum bending compressive stress corresponding to lateral buckling, $f_{cr.b}$ of non-slender rolled I-sections may be approximately calculated using the following equation:

$$f_{\mathrm{crb}} = \frac{1.1\pi^2 E}{(L_{\mathrm{LT}}/r_y)^2}\left[1 + \frac{1}{20}\left(\frac{L_{\mathrm{LT}}/r_y}{h_{\mathrm{f}}/t_{\mathrm{f}}}\right)^2\right]^{0.5}$$

The following simplified conservative equation may be used in the case of prismatic members made of standard rolled I-sections and welded doubly symmetric I-sections for calculating the elastic critical lateral buckling moment.

$$M_{cr} = \frac{\pi^2 EI_y h_f}{2L_{LT}^2}\left[1 + \frac{1}{20}\left(\frac{L_{LT}/r_y}{h_f/t_f}\right)^2\right]^{0.5} = \beta_{\mathrm{b}} Z_{\mathrm{p}} f_{\mathrm{cr,b}}$$

where

$f_{\mathrm{cr,b}}$ = lateral torsional buckling stress;

I_{w} = warping constant;

I_{t} = torsional constant = $\sum b_{\mathrm{i}}\, t_{\mathrm{i}}^3 / 3$ for open sections;

I_{y} = moment of inertia about the weak axis;

r_{y} = radius of gyration of the section about the weak axis];

L_{LT} = effective length for lateral torsional buckling;

h_{f} = Center to center distance between flanges; and

t_{f} = thickness of the flange.

M_{cr} for different beam sections, considering loading, support condition, and non-symmetric cross-section, shall be more accurately calculated using the method given in as per good practice [C-6B(3)].

B-4.2 *Hogging Lateral Buckling Resistance of Composite Beams*

The effective unsupported length, L_{LT}, in case of bare steel section may be taken as recommended in as per good practice [C-6B(3)]. When a slab connects in the hogging moment region the top flange of two or more beams running parallel, then the effect of U-Frame action in restraining the lateral buckling of bottom flange under compression (Fig. 29) may be considered as given below:

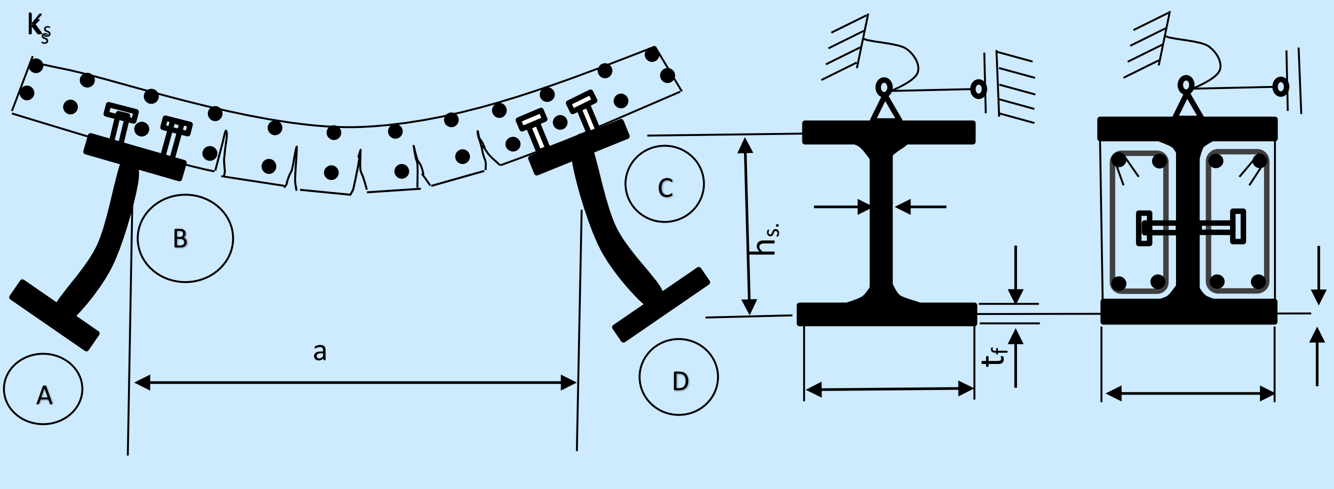


FIG. 29 INVERTED U-FRAME ACTION TO RESTRAIN LATERAL BUCKLING OF BOTTOM FLANGE

B-4.2.1 The rotational spring restraint stiffness of the concrete slab, k_s, per unit length of steel beam is given by

$$k_s = k_1\,k_2/(k_1 + k_2)$$

where

k_1 = Flexural stiffness of the cracked concrete or composite slab transverse to the spanning direction of steel beam = $\alpha\ (EI)_s/a$

α = 2 for an edge beam,

= 3 for inner beam and

= 4 for inner beam with four or more such beams running parallel and supporting the continuous slab;

a = span length of the slab transverse to the steel beams

$(EI)_s$ = cracked flexural stiffness of the concrete or composite slab per unit width parallel to the steel beam, taken as the lower of the sagging bending slab stiffness of the slab in between the steel beams and hogging bending stiffness of the slab at the supporting steel section;

k_2 = flexural stiffness of the steel web per unit length along the beam,

= $E_s\,t_w{}^3/[4(1 - \nu_s{}^2)h_s)]$ in un-encased steel section

= $E_s\,t_w\,b_c{}^2/[16\ h_s\,(1 + 4\ m\ t_w/b_c)]$ in encased steel section as per 8.3.8

E_s = modulus of elasticity of structural steel;

E_s = Poisson's ratio of structural steel;

t_w = thickness of the steel section web;

b_c = width of concrete encasement (Fig. 27);

h_s = distance between centroids of top and bottom flanges

m = long term modular ratio of encasing concrete as per good practice [C-6B(2)].

B-4.2.2 The torsional rigidity of the steel section may be taken as $G_s\,I_{st}$, where Gs is the shear modulus of steel, I_{st}, is the St. Venant's torsion constant of the steel section. The torsional rigidity stiffness contribution of encasing concrete may be taken as being equal to $G_c I_{ct}/10$, where G_c, may be taken as equal to 0.3 E_s/m and I_{ct} is the St. Venant's torsion constant of encasing concrete of rectangular shape and m is the modular ratio for long term effects.

B-4.2.3 The elastic hogging critical buckling moment of the composite beam at an internal support of a continuous beam is given by:

$$M_{cr} = (k_c C_4/L)\ [(G_s\,I_{st} + k_s\,L^2/\pi^2)\ E_s\,I_{ybf}]^2$$

where

I_{ybf} = moment of inertia of the bottom flange about the minor axis of the steel section;

I_{zco} = second moment of the equivalent area, A_{co}, of the cracked composite beam section for major axis bending;

K_c = composite beam section property = $(h_s\,I_{zc}/I_{ys})/[(h_s^2/4 + (I_{ys} + I_{zs})/A_s)/e + h_s]$;

e = $A_{co}\,I_{zs}/[A_s\,Z_c\,(A_{co} - A_s)]$;

h_s = distance between the centers of the flanges of the steel section;

I_{ys}, I_{zs} = second moment of area of steel section about the minor and major axis, respectively;

Z_c = distance between the centroid of steel section and the mid depth of concrete slab; and

C_4 = constant depending upon the bending stress distribution over the span length as given in Table 20 and Table 21.

For equilibrium, $F_{st} = F_{sc} + F_{cc}$

where

F_{st} = Tensile force in the steel section below the neutral axis;

F_{sc} = Compressive force the steel section above the neutral axis; and

F_{cc} = Compressive force in the concrete above the neutral axis.

The depth of the neutral axis is given as,

$$x_u = H - x_g$$

where

$$x_g = \frac{\frac{\alpha_{cc}}{\gamma_c}\,\eta\, f_{ck}\,[BH - b_f t_f - t_w(h - t_f)] + t_w h \frac{f_y}{\gamma_{m0}}}{\frac{\alpha_{cc}}{\gamma_c}\eta f_{ck}(B - t_w) + 2t_w \frac{f_y}{\gamma_{m0}}}$$

Bending resistance,

$$M_p = F_{sc} . X_{sc} + F_{cc} . X_{cc} + F_{st} . X_{st}$$

where

X_{sc}, X_{cc} *and* X_{st} are respectively the distance between the neutral axis of the composite beam and the individual centre of gravities of the corresponding forces].

B = center-to-center distance between two filler beams;

b_{eff} = effective width of concrete for one filler beam;

b_f = width of the top flange of the steel section;

t_w = thickness of the web of steel section;

H = distance between top of concrete and bottom of bottom flange of steel beam;

h = total depth of steel girder;

x_g = distance of neutral axis from bottom of bottom flange of steel beam;

A_{st} = cross sectional area of reinforcements within the effective width of the concrete flange;

A_s = cross sectional area of steel beam of a composite section;

d_s = overall depth of the slab;

d_e = effective depth of the slab; and

M_p = ultimate bending moment.

ANNEX C

(*Clauses* 12.4.3.1 *and* 12.5.2)

COMPOSITE SLABS

C-1 GENERAL

Composite slabs consist of metal decking spanning between the supports and acting integrally with the concrete after the concrete hardens (Fig. 31). The steel decking performs several roles as given below:

a) It supports loads during construction and acts as a working platform;

b) It develops adequate composite action with concrete to resist the imposed loading;

c) It transfers in-plane loading by diaphragm action to vertical bracing or shear walls;

d) It may stabilize the compression flanges of the beams against lateral buckling until the concrete hardens;

e) It reduces the volume of concrete in the tension zone of the slab; and

f) It distributes shrinkage strains, thus preventing serious cracking of concrete.

STEEL PROFILED DECKING
BEAM

FIG. 31 COMPOSITE SLAB

C-2 STRUCTURAL ELEMENTS

C-2.1 Composite floors with profiled decking consist of the following structural elements along with in-situ concrete and steel beams:

a) Profiled decking;

b) Shear connectors; and

c) Reinforcement for shrinkage and temperature stresses.

Connections between the structural steel beam and decking elements are generally designed as 'simple', that is, not moment-resisting. Stud shear connectors are welded through the sheeting onto the top flange of the beam to facilitate the shear transfer between concrete and steel decking, serving as end anchorage, as well as the shear transfer between the slab and steel beam for mobilising composite action along the beam span.

C-2.2 Profile Decking

The steel deck is normally rolled into the desired profile from 0.9 mm to 1.5 mm galvanized coil sheets. It is profiled such that the profile heights are usually in the range of 38 mm to 75 mm, and the pitch of corrugations is between 150 mm and 350 mm. Generally, composite slab spans of the order of 2.5 m to 3.5 m between the beams are chosen, and the beams are designed to span between 6 m to 12 m. There are two well-known generic types of profiles as given below (Fig. 32):

a) Dovetail profile with flange indentations; and

b) Trapezoidal profile with web indentations.

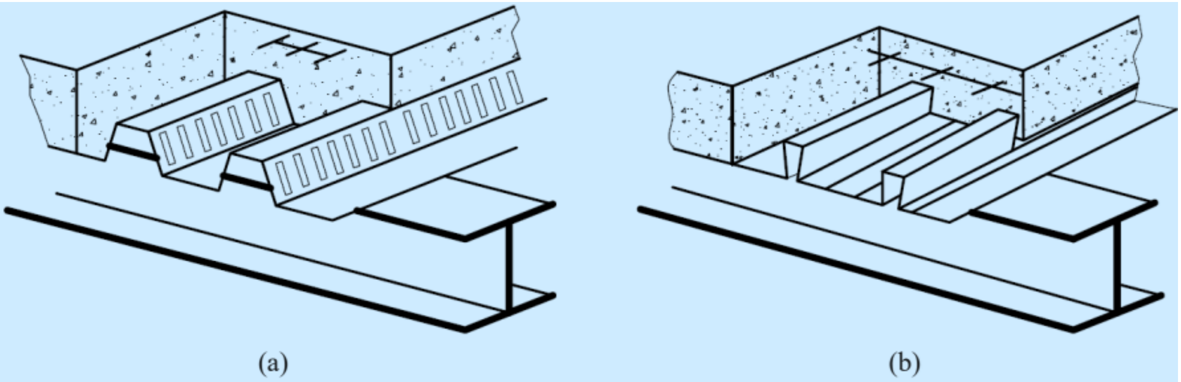

FIG. 32 COMPOSITE SLAB DECKING PROFILE

C-2.3 Shear Connectors

To enable composite action to be assumed between the profiled steel sheet and the concrete, the longitudinal shear force be transferred by the sheet by the above following form of connection (Fig. 33):

a) Mechanical interlock through the provision of indentations or embossments rolled into the profile;

b) Frictional interlock of re-entrant profile;

c) Through-deck welded stud connectors or any other local connection between the steel and the concrete; and

d) Deformation of the ends of the ribs at the ends of the sheeting.

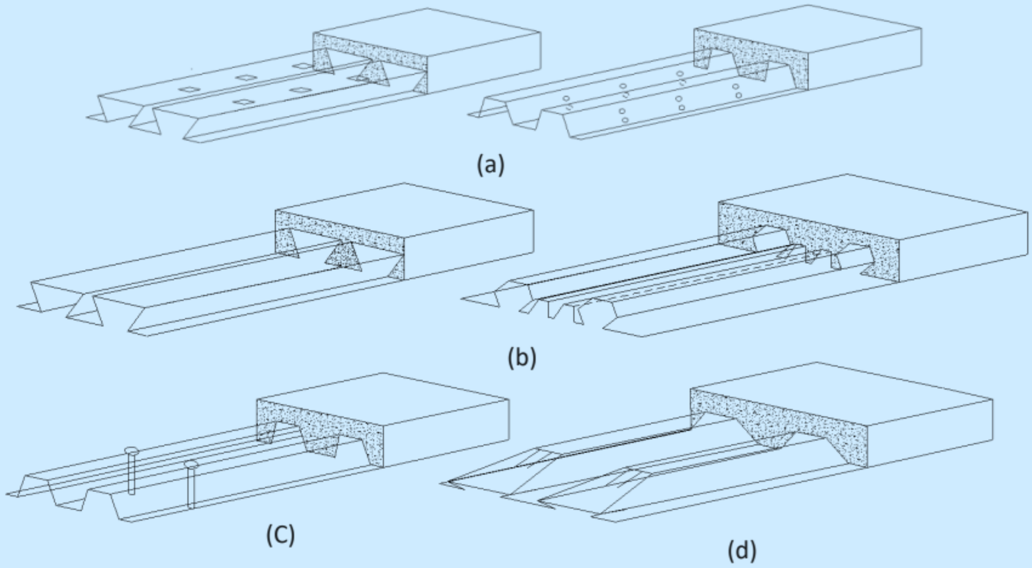

FIG. 33 TYPICAL FORMS OF SHEAR CONNECTORS IN COMPOSITE SLAB

C-2.4 Reinforcement for Shrinkage and Temperature Stresses

In buildings, the temperature difference in the slabs is negligible; thus, there is no need to provide reinforcement to account for temperature stresses. The effect of shrinkage is to be considered, and the total shrinkage strain for design may be taken as 0.003 in the absence of test data.

C-3 PONDING OF PROFILED DECKING

Fig. 34 shows ponding of the profiled deck. In unpropped construction, the profiled decking acting as a formwork to support wet concrete and construction imposed load. Due to this, the deck sheeting may deflect and cause an increase in the thickness of concrete at or closer to mid-span. This is referred to as 'Ponding.' Ponding increases the volume of concrete consumed as well as dead load. These effects should be accounted for, particularly in long spans.

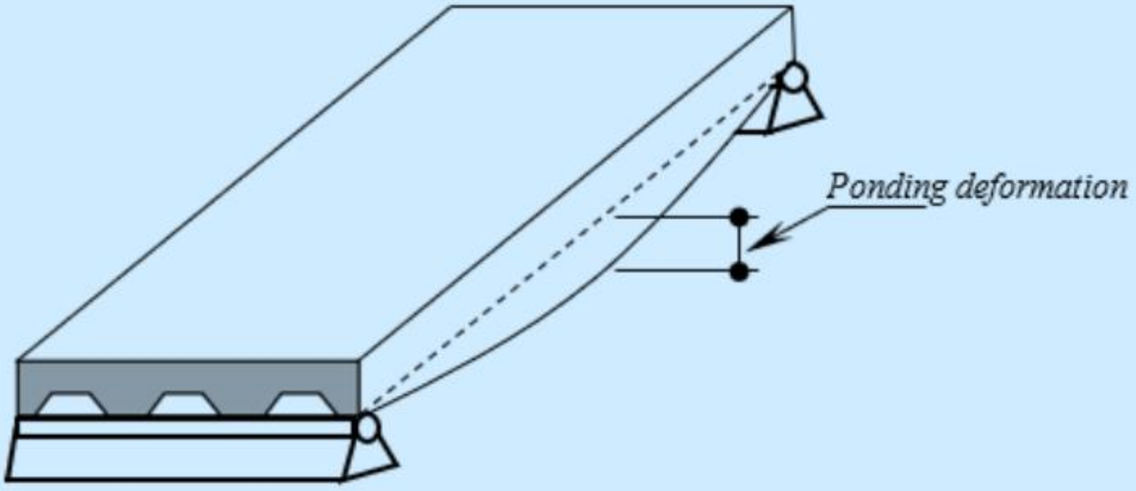

FIG. 34 PONDING IN PROFILE DECKING DUE TO WEIGHT OF CONCRETE SLAB

C-4 BENDING RESISTANCE OF COMPOSITE SLAB WITH FULL SHEAR CONNECTION

NOTE — In C-4, instead of the usual F_{cc}, the concrete compressive force is denoted as F_{ccf} to represent the concrete compressive force with a full shear connection.

C-4.1 Sagging Bending Resistance [Neutral Axis is above the Steel Decking (Fig. 35)]

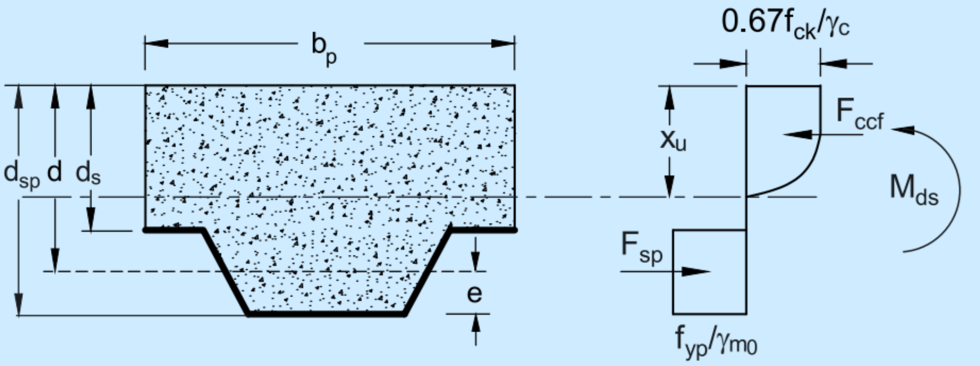

FIG. 35 STRESS DISTRIBUTION UNDER SAGGING BENDING MOMENT ($X_u < D_s$)

The design stress distribution is shown in Fig. 35. This is valid when $x_u \leq d_s$, that is, when the neutral axis lies above steel decking. Centroid of concrete force lies at $0.42x_u$ from top concrete surface. The equations for the design resistance are given in Table 22.

C-4.2 Sagging Bending Resistance [Neutral Axis is within the Steel Decking (Fig. 36)]

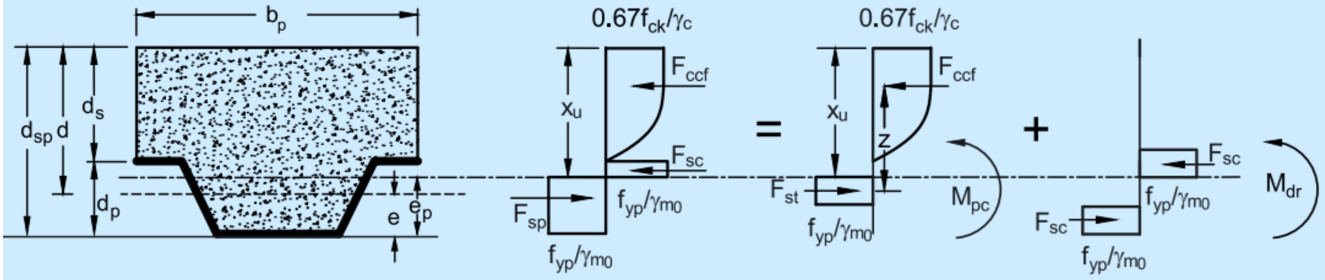

FIG. 36 STRESS DISTRIBUTION UNDER SAGGING BENDING MOMENT ($x_u > d_s$)

The design stress distribution is shown in Fig. 36. This is valid when $x_u > d_s$, that is. when the plastic neutral axis lies in the steel decking. The depth of the parabolic compressive stress block in concrete is between the top of the concrete slab to the top fibre of the deck sheet as shown in Fig. 36. Also, e_p is the distance between the plastic neutral axis of the composite slab to the extreme fibre of the deck sheet in tension and e is the distance between the centroidal axis of the profiled steel sheeting to the extreme fibre of the deck sheet in tension. The centroid of concrete force F_{ccf} lies at $0.42d_s$ from top of the concrete surface. The equations for the design resistance are given in Table 22. The value M_{dp} used in Table 22 is plastic moment capacity of the deck sheet which may be provided by the manufacturer or calculated independently.

C-4.3 Hogging Bending Resistance of Composite Deck

The contribution of steel decking is neglected. The design stress distribution is shown in Fig. 37. This is valid when x_u is in the range of $(d_s < x_u < d_{cp})$, that is., when the neutral axis lies in the steel decking. The centroid of concrete force lies at $0.42x_u$ from the bottom concrete surface b_0 the concrete width at the neutral axis is to be evaluated by trial and error. The equations for the design resistance are given in Table 22.

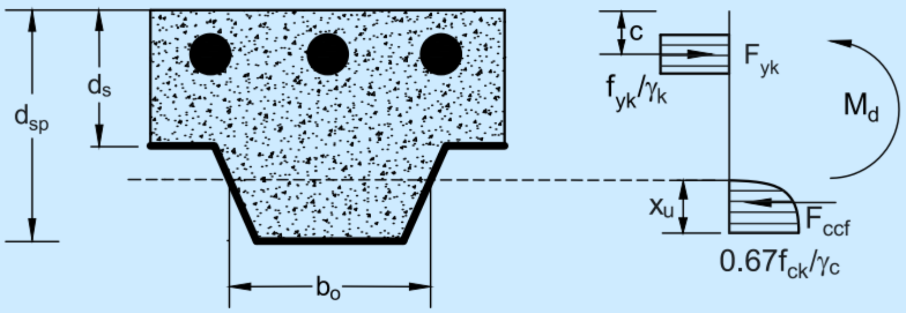

FIG. 37 STRESS DISTRIBUTION UNDER HOGGING BENDING MOMENT ($d_s < x_u < d_{sp}$)

Table 22 Design Moment Capacity, M_{ds}, of Composite Slabs with Full Shear Connection

(*Clauses* C-4.1, C-4.2 *and* C-4.3)

Case	**Position of Plastic Neutral Axis**	**Value of x_u**	**Design Moment Capacity, M_{ds}**
(1)	(2)	(3)	(4)
1	Sagging moment, NA above sheeting material (Fig. 35)	$x_u = \frac{A_p f_{yp}/\gamma_{mo}}{0.36 f_{ck} b_p} \leq d_s$	$M_{ds} = \frac{A_p f_{yp}}{\gamma_{mo}}(d - 0.42x_u)$
2	Sagging moment NA within the steel decking (Fig. 36)	$x_u > d_s$ A simplified stress block is shown in Fig. 36. Using which M_{ds} is calculated without the need for x_u	$M_{ds} = F_{ccf}z + M_{dr}$ $M_{dr} = 1.25\, M_{dp}\left[1 - \left(\frac{F_{ccf}}{A_p f_{yp}/\gamma_{mo}}\right)\right] < M_{dp}$ $z = d_{cp} - 0.42d_S - e_p + \frac{F_{ccf}}{F_{sp}}(e_p - e)$ $F_{ccf} = 0.36 f_{ck} b_p d_s$ $F_{sp} = \frac{A_p f_{yp}}{\gamma_{mo}}$
3	Hogging moment (Fig. 37)	$x_u = \frac{\frac{A_{st} f_{yk}}{\gamma_k}}{0.36 f_{ck} b_o}$	$M_d = \frac{A_{st} f_{yk}}{\gamma_k} \times (d_{sp} - c - 0.42x_u)$

Notations:

A_{st} – area of the reinforcing bar within one wave length b_s of decking sheet

d – distance between the C.G axis of the profiled steel sheeting and the extreme fibre of the composite slab in compression $(d_{sp} - e)$

e – distance between the C.G axis of the profiled steel sheeting and the extreme fibre of the composite slab in tension

e_p – distance between the plastic neutral axis and the extreme tension fibre of the composite slab.

b_p – distance between the centres of adjacent ribs or one wave length of a profile deck

A_p – effective cross-sectional area of profile decking sheeting

M_{dr} – design bending resistance of profile decking sheeting

M_{ps} _ Plastic moment of resistance of the profile decking sheeting

f_{ck} – characteristic compressive strength of concrete

f_{yp} – yield strength of profile decking sheeting

d_{sp} – total depth of the composite slab $(d_{sp} = d_s + d_p)$

C-5 BENDING RESISTANCE OF COMPOSITE SLAB WITH PARTIAL SHEAR CONNECTION

NOTE — In C-5, instead of the usual F_{cc}, the concrete compressive force is denoted as F_{ccp} to represent the concrete compressive force with a partial shear connection.

C-5.1 The stress distribution in slabs with partial shear connection is similar to Fig. 37. However, the compressive force in the concrete above the neutral axis ($F_{ccp} < F_{ccf}$) is controlled by the interface shear resistance due to the partial shear connection. The interface shear resistance is obtained from tests. The details of tests to obtain the shear strength between the interface of decking and concrete is given in **C-5.2**.

C-5.2 Shear Resistance of Composite Slab

The longitudinal shear behaviour may be considered as ductile if the failure load exceeds the load causing a recorded end slip of 0.1 mm by more than 10 percent. If the maximum load is reached at a mid-span deflection exceeding $L/50$, the failure load shall be taken as the load at the mid-span deflection of $L/50$. Otherwise, the behaviour is classified as brittle.

The shear resistance due to the chemical bond shall not be considered. This clause is applicable to the composite slabs with the mechanical or frictional interlock. Literature gives two main methods for determining the shear transfer for partial shear connection from test results. They are (i) the m-k method and (ii) the partial shear connection method. The m-k method is valid for both ductile and brittle failure cases but disregards the effect of overhang beyond the support, whereas the partial shear connection method is valid only for ductile behaviour, but accounts for the effect of the support reaction and the overhang beyond the support.

C-5.2.1 *m-k Method for Composite Slabs without End Anchorage*

The m-k method is based on establishing the gradient and intercept of an assumed linear relationship between two parameters of the slab, obtained from two groups of composite slab tests. The evaluation of m-k values is illustrated in Fig. 38.

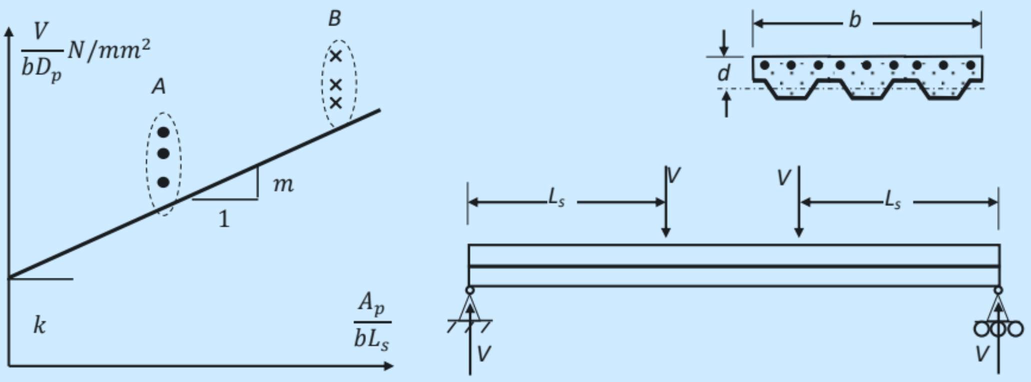

FIG. 38 TEST SETUP TO EVALUATE *M-K* VALUES

For cases when the longitudinal shear behaviour may be considered ductile, V is taken as the value of the support reaction at the failure load. However, if the behavior is brittle, the value should be reduced using a factor 0.8. By plotting the results from the composite slab tests in terms of the vertical shear parameter [$V/(b\,D_p)$] against the shear bond parameter [$A_p/(b\,L_s)$] for two groups of data corresponding to the long specimens (Group-A) and the short specimens (Group-B). The relationship between vertical shear and shear bond capacity is approximated by constructing a straight line through the two groups of data (Fig. 38). The effect of any overhang in the test specimen is neglected in the m-k method, unlike in the partial shear connection approach.

From all the values of V, 5 percent fractile of the characteristic shear strength linear regression line should be calculated to define the characteristic m and k values (Fig. 38). The minimum value of each group is further reduced by 10 percent for design consideration if two groups of three tests are used and the deviation of any individual test result in a group does not differ by more than 10 percent from the mean.

If the m-k method is used, it should be shown that the maximum design vertical shear V for a width of slab ‘b’ does not exceed the design shear resistance V_{ld} specified in Table 23.

C-5.2.2 *Partial Interaction Method*

The degree of shear connection η is defined as,

$$\eta = \frac{F_{\mathrm{ccp}}}{F_{\mathrm{ccf}}}$$

where

F_{ccp} = compressive force in the concrete as governed by partial shear transfer, as obtained from a standard tests; and

F_{ccf} = compressive force in the concrete for full shear connection as given in **C-4**.

The variation in bending resistance with the degree of shear connection is shown in Fig. 39. In case $\eta = 0$ composite action between the steel sheet and the concrete does not exist, and it is assumed that the bending resistance is provided by the bending resistance, M_{dp}, of profiled steel sheet alone. For the case $\eta = 1$, in the full shear connection, the full tensile resistance of the sheet is developed, or the full compressive resistance of concrete above the ribs of the sheet is attained. For intermediate cases such that $0 < \eta < 1$, the partial shear connection exists. Typical behaviour of open trough profile steel sheeting with partial shear connection is illustrated in Fig. 39.

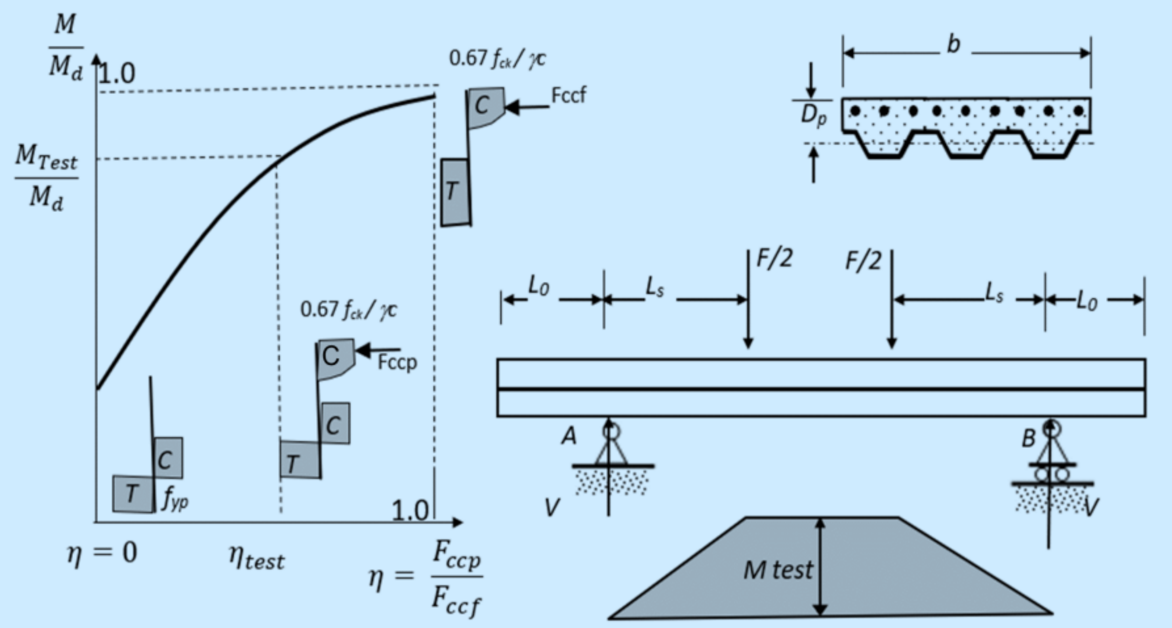

FIG. 39 TEST TO DETERMINATION OF THE DEGREE OF THE PARTIAL SHEAR CONNECTION

For a given bending resistance, the degree of shear connection provided in the test η_{test} can be assessed from the points on the partial shear interaction curve in Fig. 39. By neglecting the effect of the support reaction, the longitudinal shear strength τ_u can be obtained from

$$\tau_u = \frac{\eta_{\mathrm{test}}\, F_{\mathrm{ccf}}}{b\,(L_{\mathrm{s}} + L_{\mathrm{o}})}$$

where

F_{ccf} = Compressive normal force in the concrete flange with full shear connection;

b = Width of the slab;

L_s = Shear span; and

L_o = Length of the overhang (Fig. 39).

If the additional longitudinal shear, the additional resistance caused by the friction due to the support reaction is taken into account, the equation becomes

$$\tau_u = \frac{\eta_{test} F_{ccf} - \mu V}{b\,(L_s + L_o)}$$

where

μ = frictional coefficient taken as 0.5; and

V = support reaction under the test load.

The characteristic shear strength $\tau_{u.fk}$ should be calculated from the test values as the minimum value of stress below which not more than a specified percentage (usually 5 percent) of the corresponding stresses of samples tested are expected to occur. This is divided by the partial safety factor governed by the ultimate state to obtain the design value, $\tau_{u.d}$.

The determination of the design moment resistance of the composite slab with the partial shear connection is similar to the case (Fig. 39). The design bending resistance of the partial shear connection slab is evaluated using equations given in Table 23.

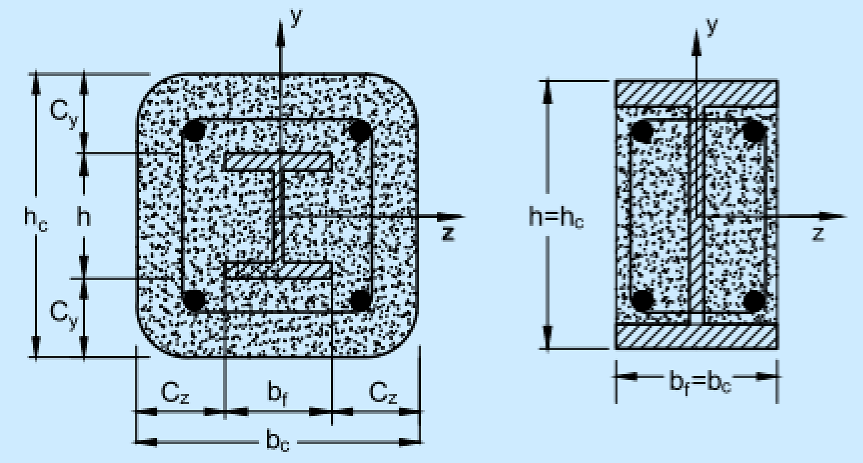
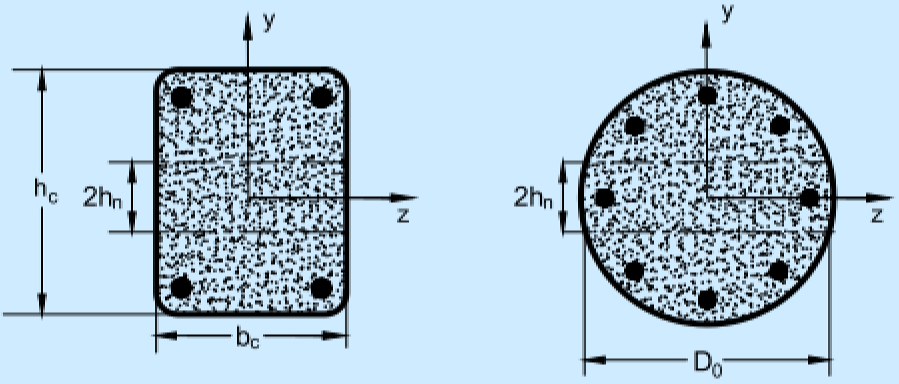
PLASTIC DESIGN RESISTANCE OF SYMMETRIC COMPOSITE COLUMNS

D-1 GENERAL

This section deals with the calculation of the design resistance of the doubly symmetric composite columns. The resistance equations are derived based on the rectangular stress block in concrete. The general dimensional view of the fully or partially concrete-encased single I-section is as given in Fig. 40 (a). The general dimensional view of the concrete infilled tubular composite column section is given in Fig. 40 (b).



a) Fully and partially concrete encased



b) Concrete infilled tubular columns

FIG. 40 TYPICAL COMPOSITE COLUMN DETAILS

The following are the notations used in this section, in addition to the dimensions shown in Fig. 40.

A_c = cross sectional area of concrete;

A_s = cross sectional area of structural steel;

A_{st} = cross sectional area of total steel reinforcement;

A_{stc} = cross sectional area of steel reinforcement in the compression zone;

f_{ck} = characteristic compressive cube strength of concrete;

f_y = minimum guaranteed yield strength of structural steel section;

f_{yk} = minimum Guaranteed yield strength of steel reinforcement;

M_d = design bending resistance under only bending moment;

M_n = ultimate bending resistance under only bending moment;

P_d = design compressive resistance under compression only;

P_n = ultimate compressive resistance under compression only;

M'_d = design bending resistance under combined bending and compression;

M'_n = ultimate bending resistance under combined bending and compression;

P'_d = design compressive resistance under combined bending and compression;

P'_n = ultimate compressive resistance under combined bending and compression;

r = inner radius of the rounded corners in RHS;

γ_c = partial safety factor for the compressive strength of concrete = 1.5;

γ_{m0} = partial safety factor for the yield strength of structural steel = 1.1; and

γ_k = partial safety factor for the yield strength of steel reinforcement = 1.15.

D-2 DESIGN COMPRESSIVE RESISTANCE OF SHORT COMPOSITE COLUMN (Point A)

The stresses on different components of the composite columns at the ultimate stage under only axial force are as shown in Fig. 41. The ultimate design compressive resistance, P_n, of the plastic, compact and semi-compact sections are given by:

$$P_n = A_s f_y + A_{st} f_{yk} + \alpha_c A_c (\alpha_{cc} f_{ck})$$

where

α_c = 0.85, for partially or fully encased column; and

α_c = 1.0, for infilled columns.

α_{cc} = 0.67

FIG. 41 STRESS DISTRIBUTION AT ULTIMATE STAGE UNDER ONLY AXIAL FORCE

The axial design resistances of different types of the composite column are given in Table 24. For concrete filled circular tubular sections in Table 24, the increase in concrete strength due to confinement may be taken, provided $\lambda \leq 0.5$ calculated using **13.5.1** and $e/d < 0.1$ where e is the eccentricity of the loading, given by the ratio of the design moment to design axial load and d is the external diameter of the circular column. If anyone of the conditions is not satisfied then $\eta_1 = 0$ and $\eta_2 = 1$.

To account for minimum eccentricity and grade of reinforcing steel, the design axial capacity can be estimated using the following expression,

$$P_d = A_s \frac{f_y}{\gamma_{m0}} + \propto_k A_{st} \frac{f_{yk}}{\gamma_k} + 0.6 \propto_c A_c \frac{f_{ck}}{\gamma_c}$$

α_k values can be taken as

Grade of Reinforcing Steel	Value of α_k
Fe250	0.90
Fe415	0.82
Fe500	0.77

FIG. 42 STRESS DISTRIBUTION AT ULTIMATE STAGE UNDER ONLY BENDING MOMENT

The design bending resistance is given by:

$$M_d = (Z_{ps} - Z_{psn}) f_y / \gamma_{m0} + (Z_{pr} - Z_{prn}) f_{yk} / \gamma_k + 0.5\, \alpha_c (Z_{pc} - Z_{pcn})\, (\alpha_{cc} f_{ck}) / \gamma_c$$

where

Z_{ps}, Z_{pr}, and Z_{pc} = Plastic section moduli of the steel section, reinforcement and concrete about their own centroidal axis, respectively (the concrete in tension region is assumed to be uncracked for this calculation).

Z_{psn},, Z_{prn} and Z_{pcn} = Plastic section moduli of the steel section, reinforcement and concrete, all within the depth h_n on both sides of the neutral axis of the gross section, about the neutral axis of gross section, respectively. (Table 25 gives equations for evaluating the value of h_n)

α_c = the strength coefficient of concrete,

= 0.85 for fully and partially encased composite sections,

= 1.0 for concrete filled hollow sections and

FIG. 43 SHORT COLUMN COMPRESSION AND BENDING INTERACTION

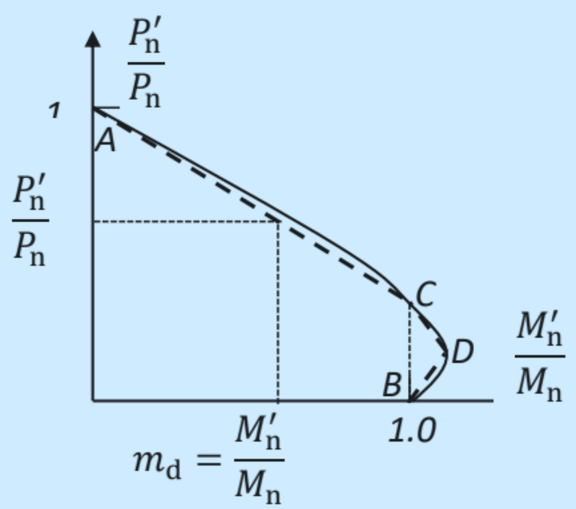

FIG. 44 INTERACTION CURVE OF A COMPOSITE COLUMN SHOWING THE POINTS A, B, C AND D

If the concrete section in compression is below the neutral axis of the gross section, h_n, is assumed. The integration of the stresses over the cross section gives the ultimate nominal compressive resistance, P'_n, for the cross section. The integration of the moment of the stresses over the cross section about the neutral axis of the gross section gives the corresponding ultimate bending resistance, M'_n. For various values of h_n, the corresponding simultaneous compressive and bending resistance of the cross section can be calculated to obtain an interaction curve as shown in Fig. 44.

It is seen that the resistance under only compression (Table 23) is a point, (A), on the curve. The resistance under only bending is point, (B), on the curve. Further, from the case of pure bending, as the axial load is increased from zero value, the bending resistance also increases until point D. Similarly, the point C corresponds to the case, where in spite of the axial compression, the ultimate plastic bending resistance, M_n, is reached.

It is tedious and time-consuming to develop the full interaction curve for every section designed. In order to simplify, the values corresponding to the points A, B, C, and D are computed and in between a straight-line variation is assumed in the design. The simplified procedure and the equations are discussed in the following sections.

The values of P_d and M_d corresponding to plastic section under pure compression (point A, Fig. 41) and pure bending (Point B, Fig. 42) are obtained as in **D-2** and **D-3**.

D-4.1 The Design Resistance at Point C (Fig. 45)

The design bending resistance corresponding to point C is the same as pure bending resistance.

$$M'_{d,C} = M_d$$

The design compressive resistance corresponding to point C on the interaction diagram is obtained as given below. The typical position of the neutral axis for points *B* is shown in Fig. 43 and at the point C in the beam-column interaction curve in Fig. 44. The location of the neutral axis from the CG of section, h_n, can be determined from Table 21. The integration of the stresses shown in Fig. 46 is equal to $P'_{pd,C}$ at point C. The axial force corresponding to point C in the interaction curve is given by the equation in Table 26.

ANNEX E

(*Clause* 16)

TESTING

E-1 TESTING OF MATERIALS

Testing of materials shall be done as per standard laid down norms given in **E-1.1** to **E-1.3**.

E-1.1 Concrete

For testing of concrete, reference shall be made to as per good practice [C-6B(2)].

E-1.2 Steel Sections

All the structural steel and accessories like rivets, bolts, nuts, washers, welding consumables, steel forging, casting, etc., shall be tested for mechanical and chemical properties as applicable and shall conform to requirements of appropriate Indian standards referred to in as per good practice [C-6B(3)]. Steel shall conform to the requirements of the accepted standard [C-6B(4)] and the accepted standard [C-6B(19)]. Bolts and bolted connection joints with high strength bolts shall be inspected according to as per good practice [C-6B(20)].

For testing of the strength, flexibility, and other relevant properties of the shear connectors, the test procedures as indicated in **E-1.3** shall be adopted.

E-1.3 Testing of Shear Studs for Steel-Concrete Interface Shear

The nominal static strength of a shear connector may be determined by push-out tests. The conditions and procedures which shall be followed while performing the tests are as indicated below:

a) The dimensions of the standard test are as shown in Fig. 48;

b) The bond at the steel-concrete interface shall be prevented by greasing the flanges or by any other suitable method;

c) The rate of application of load should be uniform and such that the failure load is reached in not less than 10 minutes;

d) The strength of the concrete f_c, at the time of testing, should not differ from the specified cube strength f_{ck} of the concrete by more than $\pm$ 20 percent;

e) Not less than three tests shall be done, and the nominal static strength P_u shall be taken as the lowest value of $f_{ck}.P / f_c$ for any of the tests, where P is the failure loads of the connectors at concrete strength f_c and f_{ck} is the characteristic cube strength of the concrete; and

f) The load-deformation curve, the ultimate resistance of the shear per shear connector, relative slip at ultimate load shall be recorded.

LIST OF STANDARDS

The following list records those standards which are acceptable as ‘good practice’ and ‘accepted standards’ in the fulfilment of the requirements of the Code. The latest version of a standard shall be adopted at the time of enforcement of the Code. The standards listed may be used for conformance with the requirements of the referred clauses in the Code.

In the following list, the number appearing in the first column within parentheses indicates the number of the reference in this Part/Section.

Sl No.	*IS No.*	*Title*
(1)	IS 456 : 2000	Plain and reinforced concrete — Code of practice (*fourth revision*)
	IS 800 : 2026	General construction in steel — Code of practice (*fourth revision*)
(2)	IS 456 : 2000	Plain and reinforced concrete — Code of practice (*fourth revision*)
(3)	IS 800 : 2026	General construction in steel — Code of practice (*fourth revision*)
(4)	IS 2062 (Part 1) : 2025	Structural steel: Part 1 Hot rolled medium and high tensile steel (*eighth revision*)
(5)	IS 1608 (Part 1) : 2018	Metallic materials tensile testing: Part 1 Method of test at room temperature (*fourth revision*)
(6)	IS 808 : 2021	Dimensions for hot rolled steel beam, column, channel and angle sections (*fourth revision*)
	IS 1161 : 2014	Steel tubes for structural purposes — Specification (*fourth revision*)
	IS 1239 (Part 1) : 2004	Steel tubes, tubulars and other wrought steel fittings — Specification: Steel tubes (*sixth revision*)
	IS 1239 (Part 2) : 2011	Steel tubes, tubulars and other wrought steel fittings — Specification: Steel pipe fittings (*fifth revision*)
	IS 1730 : 1989	Dimensions for steel plates, sheets, strips and flats for general engineering purposes (*second revision*)
	IS 1732 : 1989	Dimensions for steel bars, round and square for structural and general engineering purposes (*second revision*)
	IS 1852 : 1985	Specification for rolling and cutting tolerances for hot rolled steel products (*fourth revision*)
	IS 2062 (Part 1) : 2025	Structural steel: Part 1 Hot rolled medium and high tensile steel (*eighth revision*)
	IS 4923 : 2017	Hollow steel sections for structural use — Specification (*third revision*)
	IS 11587 : 1986	Specification for structural weather resistant steels
	IS 12779 : 1989	Rolling and cutting tolerances for hot rolled parallel flange beam and column sections
(7)	IS 1875 : 1992	Carbon steel billets, blooms, slabs and bars for forgings (*fifth revision*)
	IS 6911 : 2017	Stainless steel plate, sheet and strip — Specification (*first revision*)
(8)	IS 1030 : 1998	Carbon steel castings for general engineering purposes — Specification (*fifth revision*)
	IS 1875 : 1992	Carbon steel billets, blooms, slabs and bars for forgings (*fifth revision*)
	IS 2004 : 1991	Carbon steel forgings for general engineering purposes — Specification (*third revision*)

Sl No.	*IS No.*	*Title*
	IS 2644 : 1994	High strength steel castings for general engineering and structural purposes — Specification (*fourth revision*)
	IS 4367 : 1991	Alloy steel forgings for general industrial use — Specification (*first revision*)
(9)	IS 1148 : 2009	Steel rivet bars (medium and high tensile) for structural purposes (*fourth revision*)
	IS 1363	Hexagon head bolts, screws and nuts of product grade C:
	Part 1 : 2019	Part 1 Hexagon head bolts (size range M 5 to M 64) (*fifth revision*)
	Part 2 : 2018	Hexagon Head Screws (Size Range M 5 to M 64) (*fifth r*evision)
	Part 3 : 2018	(Style 1) Hexagon nuts (size range M 5 to M 64) (*fifth revision*)
	IS 1364 (Part 1) : 2018	Hexagon head bolts, screw and nuts products grade A and B: Part 1 Hexagon head bolts (size range M 1.6 to M 64) (*fifth revision*)
	IS 1367	Technical supply conditions for threaded steel fasteners:
	Part 1 : 2014	General requirements for bolts, screws, studs and nuts (*fourth revision*)
	Part 2 : 2002	Tolerances for fasteners — Bolts, screws, studs and nuts — Product grades a, b and c (third revision)
	Part 3 : 2017	Mechanical properties of fasteners made of carbon steel and bolts, screws and studs (fifth revision)
	Part 5 : 2018	Mechanical properties of fasteners made of carbon steel and alloy steel — Set screws and similar threaded fasteners with specified hardness classes — Coarse thread and fine pitch thread (fourth revision)
	Part C : 2018	Mechanical properties of fasteners made of carbon steel and alloy steel — Nuts with specified property classes — Coarse thread and fine pitch thread (fourth revision)
	Part 7 : 1980	Mechanical properties and test methods for nuts without specified proof loads (*second revision*)
	Part 8 : 2020	Prevailing torque type steel nuts — Functional properties (*fifth revision*)
	Part 9/Sec 1 : 1993	Surface discontinuities, Section 1 bolts, screws and studs for general applications (*third revision*)
	Part 9/Sec 2 : 1993	Surface discontinuities, Section 2 bolts, screws and studs for special applications (*third revision*)
	Part 10 : 2002	Surface discontinuities — Nuts (*third revision*)
	Part 11 : 2020	Electroplated coatings systems (*fourth revision*)
	Part 12 : 1981	Phosphate coatings on threaded fasteners (*second revision*)
	Part 13 : 2020	Hot — Dip galvanized coatings on threaded fasteners (*third revision*)
	Part 14/Sec 1: 2018	Mechanical properties of corrosion — Resistant stainless — Steel fasteners, Section 1 Bolts, screws and studs (*fourth revision*)
	Part 14/Sec 2 : 2018	Mechanical properties of corrosion-resistant stainless steel fasteners, Section 2 Nuts (*fourth revision*)
	Part 16 : 2002	Designation system for fasteners (third revision)
	Part 17 : 2005	Inspections, sampling and acceptance procedure (*fourth revision*)

Sl No.	*IS No.*	*Title*
	Part 18 : 1996	Packaging (*third revision*)
	IS 1929 : 1982	Specification for hot forged steel rivets for hot closing (12 to 36 mm diameter) (*first revision*)
	IS 2155 : 1982	Specification for cold forged solid steel rivets for hot closing (6 to 16 mm diameter) (*first revision*)
	IS 3640 : 1982	Specification for hexagon fit bolts (*first revision*)
	IS 3757 : 1985	Specification for high strength structural bolts (*second revision*)
	IS 4000 : 1992	High strength bolts in steel structures — Code of practice (*first revision*)
	IS 5369 : 1975	General requirements for plain washers and lock washers (*first revision*)
	IS 5370 : 1969	Specification for plain washers with outside diameter 3 x inside diameter
	IS 5372 : 1975	Specification for taper washers for channels (ISMC) (*first revision*)
	IS 5374 : 1975	Specification for taper washer for I-beams (1SMB) (*first revision*)
	IS 5624 : 1993	Foundation bolts — Specification (*first revision*)
	IS 6610 : 1972	Specification for heavy washers for steel structures
	IS 6623 : 2004	High strength structural nuts (*second revision*)
	IS 6649 : 1985	Specification for hardened and tempered washers for high strength structural bolts and nuts (*first revision*)
	IS 7002 : 2018	Prevailing torque type hexagon nuts (with non-metallic insert), style — Property classes 5, 8 and 10 (*third revision*)
(10)	IS 813 (Part 1) : 2018 ISO 2553:2013	Welding and allied processes symbolic representation on drawings-welded joints (*second revision*)

FOREWORD

This NBCS (Part C/Section 7) gives recommendations regarding modular planning, component sizes, prefabrication systems, design considerations, joints and manufacture, storage, transportation and erection of prefabricated concrete elements for use in buildings and such related requirements for prefabricated concrete.

Prefabrication, though desirable for large-scale building activities, has been gaining importance in the country over the past decade. Two key aspects of prefabrication that need to be considered are the selection of an appropriate system for different categories of buildings and the sizing of their components. In this context, the principle of modular coordination is of significant value and its use is recommended.

Advantages of recent trends in prefabrication have been taken note of and also the hazards attended to such construction. Some of the essential requirements for the manufacture of the prefabricated components and elements are also included in this section.

Since the aim of prefabrication is to effect economy and improve quality and speed of construction, the selection of proper materials for prefabrication is also an important factor in the popularization of this technique. The use of locally available materials with required characteristics and the materials which, due to their innate characteristics such as lightweight, easy workability, thermal insulation, non-combustibility, etc, that effect economy and improve quality, may also be tried. However, this Section pertains to prefabricated elements with cementitious materials.

The design of prefabricated buildings shall include provision for installations of all services and required piping, wiring and accessories to be installed in the building.

This Section was first published in 1970 and was subsequently revised in 1983, 2005 and 2016 as a chapter of National Building Code of India. In the first revision in 1983, the main changes made included: inclusion of brief provision regarding importance of architectural treatment and finishes as applicable to prefabricated buildings; addition of a brief clause on the requirements of materials for use in prefabrication; elaboration of the clause on prefabricating systems and structural elements; revision of the clause on testing of components to include testing of structure or part of structure; and addition of a brief clause on the manufacture of cellular concrete.

In the second revision in 2005, this Section, earlier named as 'Prefabrication and systems building', was renamed and restructured as follows:

Section 7 Prefabrication, systems buildings and mixed/composite construction
  Subsection 7A Prefabricated concrete
  Subsection 7B Systems buildings and mixed/composite construction

In the second revision in 2005, several significant changes were introduced to enhance the standard. The modular coordination and modular dimensions of components were revised to allow greater flexibility in planning. Provisions related to tolerances were updated to address various types of prefabricated components. Additionally, a detailed clause on design requirements was incorporated to ensure the safety of prefabricated buildings against progressive collapse. Furthermore, a new clause specifying the sampling procedure for testing components was added.

In the third revision in 2016, in the Subsections 7A and 7B, several significant modifications had been incorporated. Definitions for new terms had been added and existing terminologies had been modified where necessary. Provisions related to prefabricated systems had been updated and detailed guidelines on the diaphragm action of floor systems had been included. The emulative system had been categorized and elaborated on, covering its definition, analysis, design and detailing. Design considerations had been revised to account for accidental impacts due to vehicles. Provisions and testing procedures for the water tightness of joints had been introduced, along with illustrations of typical precast joint details. Fire resistance testing of prototypes under sustained loads had been addressed and reliance solely on frictional resistance for connections between adjacent prefabricated members had been replaced with recommendations for resistance using shear. Updates have also been made to provisions on site prefabrication and vertical stacking guidelines, including restrictions on the number of components stacked on the ground. The time duration for load testing selected components from a lot had been modified. Additionally, new provisions for tolerances during erection and associated design considerations had been added. An annex had been included to address common defects, their causes and remedies, covering issues such as dimensional deviations, cracks, honeycombing, damages, strand slippage and alignment problems.

In this revision, this publication has been renamed as National Building Construction Standards (NBCS).

In this revision, it has been decided to merge subsections 7A and 7B into Section 7, 'Prefabricated Concrete Construction'. The following major modifications have been incorporated in this revision:

a) Definitions of some new terms have been added and existing terminologies modified, wherever required;
b) The emulative design approach has been adopted wherein precast elements are connected at site using wet concrete or grout;
c) Emulative system has been categorized and detailed with respect to its definition, analysis, design, detailing, etc;
d) Provisions relating to prefab systems namely moment resisting frame system, braced frame system, load bearing wall system, cell system and hybrid system are given along with their types and their applications;
e) Provisions relating to the design of corbel, bearing including dapped bearing are given in detail;
f) Provisions relating to quality control and assurance have been included;
g) Provisions for tolerances in erection and associated design considerations have been updated;
h) Provisions and testing procedures for water tightness of joints have been included;
j) A guideline for 3D printed concrete structures has been included in Annex B;
k) A comprehensive guideline on prefabricated prefinished volumetric construction (PPVC) methods, materials, design standards and performance criteria for guidance to building professionals and stakeholders involved in modular construction has been included in Annex C;
m) Guidelines for design for manufacturing and assembly has been included in Annex D;
n) Annex E on common precast connection has been modified based on the current practices in precast industry; and
p) Sustainability in precast concrete construction has been included in Annex G.

This information contained in this section is largely based on IS 15916 : 2026, 'Prefabricated concrete construction — Code of practice (*second revision*)' (*under publication*).

All standards, whether given herein above or cross-referred to in the main text of this Section, are subject to revision. The parties to agreement based on this Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

As the regulation of land development and buildings is a State subject and is dealt by the States and local bodies such as urban local bodies within their jurisdiction through building regulatory documents like building regulations, building byelaws, and fire regulations, this document is voluntary in nature and is non-binding. The implementation depends on adoption by concerned parties or stipulations in a contract or by appropriate adoption by the concerned authorities.

For the purpose of deciding whether a particular requirement of this Section is complied with, the final value, observed or calculated, expressing the result of a test or analysis, shall be rounded off in accordance with IS 2 : 2022 'Rules for rounding off numerical values (*second revision*)'. The number of significant places retained in the rounded off value should be the same as that of the specified value in this Section.

This Page has been Intentionally left blank

Important Explanatory Note for Users of the NBCS

In any Part/Section of this NBCS, where reference is made to **‘good practice’** in relation to design, constructional procedures or other related information, and where reference is made to **‘accepted standard’** in relation to material specification, testing, or other related information, the Indian Standards listed at the end of the Part/Section shall be used as a guide to the interpretation.

At the time of publication, the editions indicated in the standards were valid. All standards are subject to revision and parties to agreements based on any Part/Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

In the list of standards given at the end of a Part/Section, the number appearing within parentheses in the first column indicates the number of the reference of the standard in the Section. For example:

a) Accepted standard [C-7(1)] refers to the Indian Standard(s) give at serial number (1) of the list of standards given at the end of this Part C/Section 7, that is, IS 13920 : 2016 ‘Ductile design and detailing of reinforced concrete structures subjected to seismic forces — Code of practice (*first revision*)’,

b) Accepted standard [C-7(9)] refers to the Indian Standard(s) give at serial number (9) of the list of standards given at the end of this Part C/Section 7, that is, IS 16172 : 2023 ‘Reinforcement couplers for mechanical splices of steel bars in concrete — Specification (*first revision*)’.

NATIONAL BUILDING CONSTRUCTION STANDARDS

PART C STRUCTURAL DESIGN

SECTION 7 PREFABRICATED CONCRETE CONSTRUCTION

1 SCOPE

1.1 This NBCS (Part C/Section 7) covers provisions for prefabricated concrete construction in buildings, including prefabrication systems, design considerations, element tolerances, joints and requirements for manufacture, storage, transportation and erection.

1.2 This Section is limited to the emulative detailing approach, wherein precast elements are connected at site using wet concrete or grout with reinforcement detailing in accordance with this Section and relevant design standards.

1.3 Structural analysis shall consider appropriate computational models, including connections, and the overall performance shall be verified in terms of strength, stiffness, and ductility. The design intent shall be to achieve performance comparable to cast in-situ concrete construction. The design and detailing provisions specified for cast in-situ concrete in good practice [C-7(1)] shall form the basis, and the design engineer shall provide similar detailing to achieve equivalent behaviour compare to cast in situ practice. If required by the contract statement, this can be demonstrated by appropriate testing as specified by the Competent Authority and 12 in agreement with the design team and client.

1.4 Where exact replication of cast in-situ detailing is not feasible, the minimum requirements specified in this Section shall be followed. In cases not covered by this Section, alternative detailing approaches may be adopted, provided their performance is validated through testing (in terms of strength, stiffness, and ductility) as specified and approved by the competent authority in agreement with the design team and client.

2 –

NOTE — This clause is intentionally left blank.

3 TERMINOLOGY

For the purpose of this section, the following definitions shall apply.

3.1 Authority Having Jurisdiction — The authority which has been created by a statute and which, for the purpose of administering the NBCS/part, may authorize a committee or an official or an agency to act on its behalf; hereinafter called the ‘Authority’.

3.2 Basic Module — The fundamental module used in modular coordination, the size of which is selected for general application to building and its components.

NOTE — The value of the basic module has been chosen as 50 mm for the maximum flexibility and convenience. The symbol for the basic module is *M*.

3.3 Cellular Concrete — The material consisting of an inorganic binder (such as lime or cement or both) in combination with a finely ground material containing siliceous material (such as sand), gas generating material (for example, aluminium powder), water and harmless additives (optional); and/or steam cured under high pressure in autoclaves.

3.4 Components — A building product formed as a distinct unit having specified sizes in three dimensions.

3.5 Composite Members — Structural members comprising of prefabricated structural units of steel, prestressed concrete or reinforced concrete and cast in-situ concrete connected together in such a manner that they act monolithically.

3.6 Diaphragm — It is a horizontal or nearly horizontal structural system (for example, reinforced concrete floors and horizontal bracing systems), which transmits lateral forces to vertical elements that resist earthquake-induced inertia effects.

3.7 Increments — Difference between two homologous dimensions of components of successive sizes.

3.8 Light-Weight Concrete — Concrete of substantially lower unit weight (1 400 kg/m^3 to 1 800 kg/m^3) than that made with gravel or crushed stone.

3.9 Module — A unit of size used in dimensional coordination.

3.10 Modular Coordination – Dimensional coordination employing the basic module or a multimodule.

NOTE — The purposes of modular co-ordination are:

a) to reduce the variety of component sizes produced; and

b) to allow the building designer greater flexibility in the arrangement of components.

3.11 Modular Grid — A rectangular coordinate reference system in which the distance between consecutive lines is the basic module or a multimodule. This multimodule may differ for each of the two dimensions of the grid.

3.12 Multimodule — A module whose size is a selected multiple of the basic module.

3.13 Prefabricate — To fabricate concrete components or assembled units prior to erection or installation in a building.

3.14 Prefabricated Building — The partly/fully assembled and erected building, of which the structural parts consist of prefabricated individual units or assemblies using ordinary or controlled materials, including service facilities; and in which the service equipment may be either prefabricated or constructed in-situ.

3.15 Sandwich Concrete Panels — Panels made by sandwiching an insulation material between two layers of reinforced/prestressed concrete to act as insulation for composite or non-composite concrete panels.

3.16 Self Compacting Concrete — Concrete that is able to flow (650 mm in diameter) under its own weight and completely fill the voids within the formwork, even in the presence of dense reinforcement without any vibration, whilst maintaining homogeneity without segregation.

3.17 Shear Connectors — Structural elements, such as anchors, studs, channels, loops and spirals, intended to transmit the shear between the prefabricated member and the cast in-situ concrete and also to prevent separation at the interface (to transmit the interfacial shear).

3.18 System — It is a particular method of construction of buildings with certain order and discipline using the prefabricated components which are inter-related in functions and are produced based on a set of instructions.

3.19 Unit — Building component formed as a simple article with all three dimensions specified, complete in itself but intended to be part of a larger, compound unit or complete building. Examples are brick, block, floor panel, wall panel and other individual components.

3.20 Emulative Detailing System — A connection detailing system for precast concrete structures that provides a similar level of ductility equivalent to that of a conventionally designed, cast in-situ, monolithic concrete structure subjected to earthquake.

3.21 Jointed Detailing System — A connection detailing system for precast concrete structures that has individual precast components separated from each other but connected using special connections such as welded or bolted plates. These connections are not allowed as per this Section, if adopted appropriate testing needs to be carried out as per 10.

3.22 Terminology Relating to 3D Printing

3.22.1 *Extrusion-Based Concrete* 3*D Printing* — Extrusion based printing refers to the delivery of the concrete through a nozzle in the required shape and dimension, in a layer-by-layer deposition process. The nozzle can either be placed on a gantry or attached to a central robot or a rail mounted mechanism.

3.22.2 *Binder Jetting-Based* 3*D Printing* —Binder jetting is a 3D printing technology in which a liquid binding agent (water) is sprayed on the surface of a thin layer of the binder (cement and aggregate) to attain the required shape and dimensions. A new layer of the binder is then placed on the top of the existing layer, and the process of spraying the water is repeated. This process is continued until reaching the required height of the object. The formed object is allowed to harden before removing the excess unreacted binder.

3.22.3 *Print Plane* — The plane on which the material is deposited.

3.22.4 *Directions in the Printed Specimens* — The performance of the printed specimen varies with the principal directions of the printed concrete. The directions of the printed concrete are designated as X, Y and Z with reference to the print pathway, where:

a) X direction is parallel to the print direction and in the print plane;

b) Y direction is perpendicular to the print direction in the print plane and could cross different layers; and

c) Z direction is perpendicular to the print direction and print plane, crossing many printed layers.

3.22.5 *Concrete for* 3*D Printing* — Concrete is a composite material with cement (ordinary Portland cement blended with or without supplementary cementitious materials), water, fine aggregate, coarse aggregate and admixtures. Fine aggregates and coarse aggregate need to comply with the requirements of good practices [C- 7(2)] and [C-7(3)]. Aggregates can be used in the mix subjected to testing and validation, confirming to the required printable properties like pumpability, buildability and extrudability.

3.22.6 *Printable Concrete* — Printable concrete is a mixture of cement (with or without supplementary cementitious materials), water, aggregates and admixtures that can be extruded through the nozzle of the printer and attain the designed dimension within certain tolerance zone on placing additional layers.

3.22.7 *Buildability* — Buildability is the ability of the printed layers to develop adequate green strength to withstand the self-weight as well as load due to subsequent layers without significant geometrical deformation or collapse of the freshly printed component.

3.22.8 *Extrudability* — Extrudability is the ability of the mixture to pass through the nozzle under pressure and attain the designed shape after the extrusion.

3.22.9 *Pumpability* — Pumpability is the ease of transporting concrete mixture from the pump to the nozzle.

3.22.10 *Printability* — The printability of the mixture is a combination of the pumpability and extrudability.

3.22.11 *Open Time* — Open time represents the time over which the 3D printing mixture remains printable. This defines the time period in which the mixture can be delivered through the pumping system and dispensed through the nozzle without clogging of the extrusion system.

3.22.12 *Filament* — The extruded shape is termed as the filament. The cross section of the filament can be circular, rectangular, or square, depending on the shape of the nozzle. The filament is characterised by its diameter (for circular nozzle) or by its orthogonal dimensions – width and thickness. However, it can be of any shape.

3.22.13 *Layer* — A layer is the object formed with a single pass of the printer. Multiple layers are stacked one over the other to build up the full object. Each layer is characterized by the height or thickness, for rectangular or square nozzles.

3.22.14 *Bond* — Bond is an interface between successive layers or filaments of a 3D printed concrete specimen. The interface between layers can be called as 'horizontal' bond, while the interface between filaments side by side can be called as 'vertical' bond.

3.22.15 *Shape Stability* — Shape stability is the ability of the printed component to maintain the dimension as subsequent layers are placed.

3.22.16 *Base Layer* — A base layer is the first printed layer on which all following layers are built on.

3.22.17 *Dead Zone Length* — The dead zone length is defined as the length of static deposition of concrete or where the material flow stops such as near the nozzle with rapid change in cross section.

3.22.18 *Extracted Specimen* — Specimen of the required dimension which is extracted (cored/sawn) from the 3D printed concrete elements in any orientation.

3.22.19 *Speed of Extrusion* (*Extrusion Speed*) — The rate at which the extrusion system moves while extruding the concrete. Generally expressed in length/unit time, volume/unit time, or mass/unit time.

3.22.20 *Admixtures*

3.22.20.1 *Superplasticizers* — Superplasticizers are required in 3D printed mixes in order to control the workability of concrete and make it suitable for pumping and extrusion.

3.22.20.2 *Accelerators* — Accelerators are admixtures added to the concrete to decrease the initial setting time and increase the early-age strength.

3.22.21 *Viscosity Modifier* — An admixture that when added to the concrete, modifies the viscosity of the mix.

3.22.22 *Out-of-Plane Deformation* — Distortion/bending of the printed layers from the predefined (vertical) plane of the specimen. Intentional cantilevering or offset shall be allowed and is not considered as out-of-plane deformation.

4 NOTATIONS AND SYMBOLS

The notations used in this section are given at Annex A.

5 MATERIALS

The relevant materials for precast structures shall satisfy the requirements given in the following sections. For addressing sustainability aspects in selecting materials, a reference may be made to Annex G (*see* **G-2** and **G-5**).

5.1 Concrete Ingredients

5.1.1 *Cement*

The cement shall be selected in accordance with good practices [C-7(2)] to provide minimum required strength for lifting, transportation and durability. Each shipment of cement shall be referenced to a certified mill test report that indicates compliance with the specified type of cement. However, accelerated tests shall be carried out before application.

5.1.2 *Mineral Admixtures*

For mineral admixtures, the provisions of Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS shall apply, unless otherwise specified by the client or the design.

5.1.3 *Aggregates*

Aggregates used in concrete shall comply with accepted standard [C-7(4)]. All aggregates must be sourced from approved suppliers, with representative samples tested according to the requirements specified in the governing standards. The desired concrete properties must be demonstrated through trial mixes to ensure compliance and satisfactory performance.

The provisions of good practice [C-7(2)] shall apply while deciding the maximum and minimum size of coarse aggregate.

For stitch joints between precast elements with thickness less than 75 mm, the maximum size of aggregate shall be limited to 10 mm.

5.1.4 *Water*

Water used for concrete mixtures shall conform to Part C ‘Structural Design, Section 5 Structural Concrete’ of this NBCS. In addition, mixing water shall be free from deleterious matter that may interfere with the setting or strength development of the concrete. Water shall be tested based on the batching requirements at least once a month.

5.1.5 *Chemical Admixtures*

5.1.5.1 All chemical admixtures such as accelerating admixtures, retarding admixtures, water-reducing admixtures, air-entraining admixtures and super-plasticizing admixtures shall comply with accepted standards [C-7(5)].

5.1.5.2 Admixtures containing chloride ions shall not be used.

5.1.5.3 Admixtures must be checked for compatibility with cement and other admixtures to ensure proper performance. A trial mix program shall evaluate slump, stability, workability, air content and strength under typical conditions, including temperature and humidity. The effect of dosage variations and the order of admixture addition shall be determined from supplier recommendations or trial.

5.1.5.4 Synthetic or natural pigments may be used in precast facade or decorative elements to achieve desired colours. The pigments must be insoluble in water, free of soluble salts, acids, calcium sulphate and resistant to sunlight, alkalis and weak acids. The pigment type and amount must not affect concrete setting time or strength.

5.2 Concrete Mix Design

Qualification of a concrete mix for use in precast concrete production shall be through laboratory testing, production trials and quality control testing. The minimum grades of concrete shall be as per good practices [C-7(2)].

5.2.1 *Mix Development*

5.2.1.1 Concrete mixes for precast elements shall be determined through laboratory methods, complying with Part C ‘Structural Design, Section 5 Structural Concrete’ of this NBCS exposure class requirements. The mix shall meet project needs, service conditions and desired surface finish (colour and texture), with adequate workability for proper placement and consolidation. Water use shall be minimized to the amount necessary for proper placing and vibration consolidation.

5.2.1.2 For standard concrete, the mix design procedure shall be as per good practice [C-7(6)]. The good practices [C-7(2)] shall be used for the correlation between compressive strength and tensile strength, modulus of elasticity, shrinkage, creep coefficient, co-efficient of thermal expansion, etc.

5.2.1.3 Special concretes (for example, high-performance, ultra-high performance) shall be designed based on specialized literature and approved by the competent authority. The literature shall also correlate compressive strength with other properties such as tensile strength, modulus of elasticity, shrinkage, creep and thermal expansion.

5.2.1.4 Steel fibre reinforced concrete, specified in structural elements to enhance mechanical and durability properties, shall be designed using hooked, crimped or straight steel fibres as per specialized literature and with appropriate approvals from competent authority. Any construction joint in precast steel fibre reinforced concrete elements shall have reinforcement bar across the joint to transfer stresses.

5.2.1.5 Lightweight concrete may be used for non-structural precast elements (such as wall panels, facade units, and sandwich panels) to reduce the self-weight, enhance ease of handling and transportation, thermal insulation, and sound absorption. For lightweight concrete, adjustments are required during mix design to account for the lower density and altered workability. Specialized literature shall be referred and appropriate approvals from competent authority shall be obtained.

5.2.2 *Miscellaneous*

5.2.2.1 All the concrete mixes to be used in the production of precast elements shall be evaluated as trial batches, prepared in accordance with good practice [C-7(7)] under conditions that simulate the actual production and finishing as closely as possible.

5.2.2.2 If the source/manufacturer of cement, source/gradation of aggregates or source/manufacturer of admixture are changed after mix finalization, the proportions of the mix shall be validated and re-designed, if required.

5.2.2.3 When accelerated curing is to be used, the mix proportions shall be based on similarly cured test specimens.

5.2.2.4 When self-compacting concrete is used, the mix proportion shall meet the requirement of good practices [C-7(8)].

5.3 Reinforcement

5.3.1 Reinforcing bars and prestressing strands shall be in accordance with the provisions of Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS, respectively. Reinforcing steel deliveries shall be identified with a heat number least that can be correlated with a mill certificate.

5.3.2 For welding of reinforcement, the good practice [C-7(9)] and Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS shall be referred.

5.3.3 Reinforcement couplers shall comply with the accepted standard [C-7(10)].

5.3.4 If glass fibre reinforced polymer (GFRP) bars are used, the material shall conform to the requirements of accepted standard [C-7(11)]. Such bars shall be used only in precast elements with low risk, based on the decision of engineer-in-charge and client.

5.3.5 Welded wire reinforcement shall conform to accepted standard [C-7(12)].

5.3.6 Welding shall not be performed near any prestressing strand, whether tensioned or not tensioned. The prestressing strand shall not be exposed to spatter, direct heat, or short-circuited current flow.

5.3.7 Prestressing accessories shall comply with the requirements of good practice [C-7(3)].

5.3.8 Plastics for welded wire and bar supports shall be composed of polyethylene, styrene copolymer rubber-resin blends, polyvinyl chlorides and polytetrafluoroethylene. Plastics shall be alkali-resistant and have thermal properties compatible with concrete.

5.4 Grout

5.4.1 *Cementitious Grout*

5.4.1.1 Cementitious grout used in the precast application shall be as per good practice [C-7(2)].

5.4.1.2 Non-shrink non-metallic high-strength and flowable cementitious grouts shall be used for all structural joints between two precast elements having gap less than 50 mm. The grout strength shall exceed the strength of the joining member by at least 5 MPa. If the strength of the members varies, the cementitious grout with the highest required strength shall be used. For special connection, strength of the grout shall be as per 8.

5.4.1.3 For joint width more than that recommended in the grout manufacturer's guidelines or 50 mm, the grout shall be mixed with 10 mm down aggregate or self-compacting concrete or micro concrete shall be used.

5.4.2 *Chemical Grouts*

Chemical grouts shall be used as per manufacturer's guidelines and its properties shall comply with accepted standard [C-7(13)].

5.5 Mould

5.5.1 All moulds, regardless of material, shall conform to the profiles, dimensions and tolerances of precast concrete product indicated by the contract documents and the approved shop drawings.

5.5.2 Repeated use of moulds shall not cause any dimensional or planar changes that exceed allowable tolerances of the member. When exposed to temperature fluctuations or moisture, the warping or buckling of moulds shall not exceed to allowable tolerance limits.

5.5.3 Moulds exposed to external vibrations must be capable of transmitting these vibrations evenly across a sufficient area, without flexing, warping or causing plate flutter.

5.5.4 If it is planned to apply a prestressing force by jacking against the mould, the mould shall be sufficiently strong to withstand the force without buckling or wrinkling and maintain the required dimensional tolerances.

5.5.5 When different materials are used to construct the mould, they shall not affect the colour and texture of the precast concrete product intended to be installed unrendered. The mould materials shall be non-absorbent or properly sealed to prevent excessive moisture absorption to minimize variations in finish.

5.5.6 Wooden moulds shall be sealed with suitable materials to prevent moisture absorption.

5.5.7 Steel moulds shall be visually inspected before each use for rust, distortion and tightness of steel sheet joints.

5.5.8 Fibre reinforced polymer moulds shall be used for achieving localized architectural finishes.

5.5.9 Moulds shall be coated with mould release agents that permit its release without damaging or staining the concrete and without affecting subsequent coating, painting, or caulking operations. Debonding agents or wax shall be used during match casting.

5.5.10 Whenever concrete is to be painted or stained, only mould release agents compatible with the coating shall be permitted, unless surface preparation is performed to ensure good adhesion between the coating/stain and the concrete.

5.6 Hardware, Lifting Devices and Miscellaneous Materials

5.6.1 *Hardware*

5.6.1.1 Hardware refers to items:

a) To be placed on or in the structure to receive the precast concrete units (anchor bolts, angles, or plates with suitable anchors);

b) To be embedded in the concrete units for connection or for other mechanical, plumbing, glazing, miscellaneous iron, masonry, roofing works, etc; and

c) Necessary for the installation of the precast concrete units.

5.6.1.2 Hardware shall be made from ductile materials or as specified in the design. For high-strength materials, the design must ensure elastic behaviour. For testing, 12 shall be referred.

5.6.1.3 Welding of steel plates, angles, and other shapes shall be carried out by certified welders in conformance with standard procedures. The size, length, type and location of all welds shall conform to the approved shop drawings, and no unspecified welds shall be added without the approval of the designer.

5.6.1.4 Electrodes used for welding operations shall be bought in sealed (airtight) containers. The selection of a suitable electrode shall be made based on the material to be welded, intricacies based on the geometry of the job, thickness, weld profile and weld position. The maintenance of any electrode used shall be as prescribed by the manufacturer.

5.6.1.5 All metallic hardware surfaces that are exposed to or within 12 mm of concrete surfaces that are exposed to the weather, corrosive conditions, or condensation preferably be protected against corrosion or be made of non-corrosive materials. Hardware shall be properly cleaned before application of protective treatment. Corrosion protection shall be done as required. Care shall be taken to prevent chemicals, such as acids, from coming in contact with the hardware and causing corrosion.

5.6.1.6 Supplier of hardware shall furnish records of compliance to specification requirements and mill certificates for the material used. Review of hardware fabrication shall be performed by quality control personnel.

5.6.2 *Lifting Devices*

5.6.2.1 Lifting devices shall be capable of supporting the element in all positions planned during manufacture, storage, delivery and erection. Safe loads for lifting inserts or hooks or devices shall be supplied by the manufacturer of proprietary devices. Information on the use and installation of the devices to ensure proper performance shall be supplied by the manufacturer. For factor of safety and capacity of lifting inserts or hooks, 7 and 8 shall be referred, respectively. For testing, 12 shall be referred.

5.6.2.2 If the lifting device is subjected to dynamic loads, it shall preferably be fabricated using ductile materials or shall be designed to remain elastic.

5.6.2.3 Reinforcing bars provided as main reinforcement in the members shall not be used as lifting hooks. Separate reinforcing bars of required grade, bent to the correct size and shape, may be used exclusively as lifting hooks, with adequate embedment or anchorage whining the precast member. Where necessary, smooth rebars with adequate embedment length shall be used as lifting hooks. Lifting hooks made of reinforcing bars shall not be used for multiple handling applications.

5.6.2.4 Each bar size and configuration shall be considered such that it meets load and handling requirements.

5.6.2.5 Coil rods and bolts shall not be welded when used in lifting operations.

5.6.2.6 Connection hardware shall not be used for lifting or handling unless carefully reviewed and approved by the site engineer/designer.

5.6.2.7 Shop drawings shall clearly define insert dimensions and locations for fabrication and placement or refer to standard details.

5.6.2.8 Members incorporating embedded hardware shall be provided with corrosion protection during long-term storage.

5.6.3 *Surface Finishes and Coating*

5.6.3.1 All surface finishes and coating on precast concrete units shall be as stated in the shop drawing.

5.6.3.2 When specified in the project requirements, for finishing processes such as sandblasting, acid etching, surface retardation, the use of mould liners, or the application of veneer facing materials may be employed to achieve the desired surface appearance. These methods shall help control form joints, form blemishes and air voids within acceptable limits.

5.6.3.3 Based on project requirements and client specifications, curing compounds for precast elements shall be chosen for compatibility with coatings, moisture retention, and ease of removal. Only membrane-forming compounds that meet standards for water retention and curing efficiency shall be used. Application should occur immediately after demoulding to prevent moisture loss and ensure proper strength. The surface must be free of dust or laitance, and curing must be uniform to avoid streaking. Curing compounds shall be non-residual or removable when subsequent coatings are applied.

5.6.3.4 Based on project requirements and client specifications, anti-carbonation coatings shall be selected for CO_2 diffusion resistance, breathability and UV stability, conforming to durability standards. They must be tested for permeability and adhesion on precast surfaces. Application should occur on clean, dry, fully cured concrete, free from laitance, dust and form oil. Coatings must be applied evenly to avoid streaks and ensure effective protection.

5.6.3.5 Based on project requirements and client specifications, paints used on precast elements shall be alkali-resistant, weatherproof, and compatible with the concrete substrate. Selection shall be based on exposure conditions, including moisture, UV and chemical resistance requirements. Before application, the surface must be properly primed and any efflorescence or moisture-related defects must be addressed to prevent peeling or discoloration. Roller or spray application shall ensure uniform coverage and multiple coats shall be applied as required to achieve the desired opacity and aesthetic consistency.

5.6.3.6 Based on project requirements and client specifications, epoxy coatings, selected for chemical resistance, adhesion, impact resistance and fire rating, are used for flooring, structural connections and corrosion protection. Surfaces must be clean and dry, with a primer applied for better bonding. Curing conditions should be controlled, and components must be mixed correctly and applied evenly to avoid uneven gloss or discoloration.

5.6.3.7 Based on project requirements and client specifications, polyurethane or hybrid sealants for external precast joints shall be compatible with concrete, offer high elongation (for grouted joint 200 percent or more, for non-grouted joints 400 percent or more) and resist UV and environmental degradation. Selection should consider joint movement, exposure and adhesion. Joints must be clean, dry and free of contaminants before application, with a primer used if needed. Proper tooling is essential to ensure seamless finishes and prevent air pockets. Sealants in grouted joints act as moisture barriers, so their lifespan shall be verified.

5.6.4 *Insulation Material*

5.6.4.1 Rigid foam insulation for precast elements shall be selected based on thermal resistance, compressive strength and moisture resistance. Expanded polystyrene, extruded polystyrene, polyurethane or polyisocyanurate, etc, are preferred for long-term efficiency. Panels must conform to accepted standard [C-7(14)] or relevant manufacturer guidelines for density, strength and thermal conductivity. Panels shall be precisely cut for a snug fit to minimize thermal bridging. Exposed foam surfaces must be protected with coatings for durability and UV resistance. Foam with strength more than 10 MPa or as per design may be used in flooring to reduce concrete weight and thickness.

5.6.4.2 Mineral wool insulation shall be selected for its fire resistance, acoustic properties, and vapour permeability. Rigid or semi-rigid panels shall be used to withstand the casting process without compression. Mineral wool products conforming to accepted standard [C-7(15)] or any relevant manufacturer's guidelines shall possess thermal conductivity, density, moisture absorption and fire resistance requirements. Before placement, mineral wool boards shall be dry, securely positioned and properly supported to prevent displacement when concrete is poured. Special care shall be taken to prevent fibre shedding, which can affect worker safety and surface finish. If exposed, mineral wool shall be coated or encased to prevent moisture absorption and fibre degradation over time.

5.6.4.3 Lightweight concrete used for insulation layers in precast elements shall be selected based on its density, thermal performance and compatibility with structural concrete. Autoclaved aerated concrete and non-autoclaved cellular concrete conforming to accepted standard [C-7(16)] shall be used or relevant manufacturer's guidelines shall be followed. Proper mix design and curing conditions shall be maintained to achieve uniform density and minimize shrinkage or cracking. During production, the interface between lightweight and normal concrete layers shall be well bonded to prevent delamination. Surface smoothness and uniformity shall be checked, as inconsistencies may affect finishing and overall insulation performance.

5.7 Connections

In addition to the requirements in 5.6.1, the materials of a connection shall be selected such that embrittlement of any part of the assembled connection do not occur. Non-ferrous inserts shall be resistant to electrolytic action and alkali attack. If more than one material is used in a connection, abutting materials shall be selected such that corrosion is not induced. Dissimilar metals shall not be embedded near or in direct contact in moist or saturated concrete unless it is ensured that detrimental chemical or electrochemical (galvanic) reactions do not occur. For continuity of rebar, grouted coupler, grout filled tube or lapping of rebar shall be used. However, depending on seismic requirements the type of continuity method shall be selected. For testing and performance evaluation 12 shall be referred.

5.7.1 *Wire Loop System — Loop Box*

5.7.1.1 The wire loop system (proprietary product) is a load-transferring, cast-in element consisting of a box and a U-shaped wire loop for connecting prefabricated concrete elements. Generally, the joint with wire loop boxes is considered non-structural and should only be used for durability and gravity load requirements.

5.7.1.2 Relevant manufacturer's guidelines shall be used for selecting the appropriate product. In addition to that, the following points shall be considered:

a) The box and the two flexible wire loops shall be made of carbon steel sheet and high strength wire ropes, respectively. The surface of the box shall be equipped with a profiled surface to ensure sufficient bonding with the surrounding concrete;

b) Proper selection involves ensuring compliance with tensile strength requirements and alignment accuracy to prevent misfits. High-strength, non-shrink non-metallic cementitious grout is recommended to encapsulate loops fully. Care shall be taken in application to maintain uniform joint appearance, especially in exposed architectural elements;

c) The looped wire ropes shall not react with grout and form corrosion. Also, shall not be used if found having corrosion; and

d) The manufacturer shall furnish the detailed technical datasheet along with the test results corroborating the values noted in the technical datasheet. Also, the same shall be verified by the engineer-in-charge by conducting appropriate testing per batch.

5.7.2 *Grouted Coupler*

5.7.2.1 Grouted couplers (proprietary product) provide mechanical splicing of rebars between precast elements, ensuring structural continuity.

5.7.2.2 Their selection shall consider compatibility with reinforcing bar sizes and compliance with applicable standards.

5.7.2.3 Reinforcing bar ends and coupler interiors shall be clean before grouting to ensure proper bonding. A high-performance cementitious grout, characterized by non-shrink non-metallic high strength properties, high early strength shall be used to ensure effective load transfer. The grout shall meet the specified compressive strength and flowability requirements for complete void filling. Misalignment or incomplete grouting shall be addressed through inspection to maintain both functionality and appearance.

5.7.2.4 Class H coupler as per accepted standard [C-7(10)] shall be used with appropriate testing as per 12.3.1.

5.7.3 *Grout Filled Tubes* (*Dowel Tube*)

5.7.3.1 The tubes shall be corrugated to have proper bond with concrete and grout.

5.7.3.2 The length of the tube shall be as per development length or design requirements as per 7 and 8.

5.7.3.3 The tube shall be free from oil, grease or loose particles prior to installation and grouting. A high-performance cementitious grout, characterized by non-shrink non-metallic high strength properties, high early strength shall be used to ensure effective load transfer. The grout shall meet the specified compressive strength and flowability requirements for complete void filling. Adequate curing time shall be allowed for strength development. Grout shall be placed using gravity feed to ensure complete filling and venting shall ensure proper air escape. Misalignment or incomplete grouting shall be addressed through inspection to maintain both functionality and appearance.

5.7.4 *Terminators* (*Headed Bars*)

5.7.4.1 Headed bars are used in precast concrete elements to enhance anchorage efficiency by providing an enlarged head at the end of the reinforcement bar, reducing the required development length.

5.7.4.2 These bars shall be manufactured from high-strength reinforcement steel to ensure adequate ductility and mechanical performance. The heads shall be formed through welding, forging, or mechanical attachment and shall comply with the specified geometric and strength requirements. The selection of headed bars shall be based on design specifications, including grade of bar, head dimensions and load transfer capacity.

5.7.5 *Metal Inserts*

5.7.5.1 Steel plates shall be cast into precast elements to facilitate connections with other structural components for non-structural or gravity load transfer. Plates shall be made from structural-grade steel with appropriate thickness, positioned accurately during casting and securely anchored to prevent displacement.

5.7.5.2 Welded studs shall provide reliable load transfer by creating strong mechanical bonds between steel inserts and concrete. Studs shall be manufactured from high-strength steel and shall conform to applicable material and welding standards. Proper fusion and alignment shall be ensured and weld quality shall be verified through inspection to prevent structural deficiencies.

5.7.5.3 Corrosion protection, such as galvanization or stainless-steel alternatives, shall be applied based on environmental exposure conditions. Protective measures shall not interfere with mechanical performance or bonding with concrete. In exposed applications, surface finishes shall be such as to maintain aesthetic quality. Fire safety requirements shall also be verified for exposed applications.

5.7.6 *Shims*

5.7.6.1 Plastic shims shall be composed of materials that provide sufficient compressive strength (not less than 10 MPa or as required by the design) and demonstrate resistance to moisture, UV exposure, and temperature variations. They shall be dimensionally stable, free from warping or defects and sized to ensure a precise and secure fit for their intended application. Plastic shims shall be used for thicknesses up to 40 mm or less.

5.7.6.2 Metal shims shall be used for any shim thickness; however, use is preferable for thicker shims (typically greater than 40 mm). These shims shall be having higher strength and load-bearing capacity, particularly where greater stability and structural support are needed. For multi-layer shims, tack welding shall be performed between the layers to ensure a strong bond and prevent shifting or separation of the individual layers. Metal shims that are exposed to the environment or are in contact with moisture or corrosive elements shall be provided with appropriate corrosion protection. Care must be taken during installation to ensure that the corrosion protection is intact and not compromised by any mechanical processes.

6 PRECAST CONCRETE SYSTEMS

6.1 General

In precast concrete construction, the design shall address additional requirements including selection of component types, appropriate connection detailing, structural continuity, flexibility and restraint. Structural connections between elements shall be explicitly classified and designed as pinned, rigid, or ductile based on seismic performance criteria. Horizontal elements such as slabs, beams and staircases shall be detailed as simply supported or made continuous using in-situ topping, integrity reinforcement and collector elements to provide diaphragm action for lateral load transfer to the lateral force resisting system (LFRS). Vertical elements (for example, columns and walls) shall be designed as continuous members unless specifically excluded from LFRS. Beam-to-column joints not forming part of LFRS shall be designed to resist gravity loads with compatible displacements, moments based on design requirements and erection eccentricity. Such frames shall incorporate structural bracing to resist lateral forces. For selection of precast concrete system 6.2 to 6.5 shall be referred.

6.2 System Considerations

6.2.1 *Structural Concept*

Precast concrete structural systems shall be explicitly designed to ensure continuity between elements and robustness of the overall system. The selected system shall be robust and shall be designed to withstand the following:

a) Stability against progressive collapse;

b) Prevention of structural failure under all design load combinations;
c) Fire resistance as per applicable regulations;
d) Adequate ductility and energy dissipation capacity;
e) Redundancy and continuity in load paths;
f) Control of cracking within serviceability limits;
g) Acceptable deformation within serviceability limits; and
h) Durability against environmental exposure.

6.2.1.1 The structural system and each of its components shall maintain stability during all stages, including transportation, erection and service life. The following factors shall be considered for the selection of precast system:

a) Grid distances;
b) Spanning direction of slab and beam;
c) Position of columns and walls;
d) Position of load bearing walls and/or facade and/or facade at stilt;
e) Position and approximate requirements for stabilizing elements; and
f) Position of expansion joints.

6.2.1.2 The appropriate precast structural system shall be selected based on Table 1, considering building usage, architectural constraints, seismic performance requirements and constructability. The response reduction factor (R) shall be considered as per **5** of Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS.

6.2.2 *Standardization of Precast Components/Elements*

The precast components/elements shall preferably be standardized based on the structural, architectural and/or aesthetic requirements. The precast components/elements given below but not limited to, shall be used in accordance with relevant Indian Standards (*see* Part B 'Building Materials' of this NBCS) and the accepted standards, where available:

a) Reinforced/prestressed concrete channel unit;
b) Reinforced/prestressed concrete slab unit;
c) Reinforced/prestressed concrete beams;
d) Reinforced/prestressed concrete columns;
e) Reinforced/prestressed concrete hollow core slab;
f) Reinforced concrete waffle slab/shells;
g) Reinforced/prestressed concrete wall elements;
h) Hollow/solid concrete blocks and battens;
j) Precast planks and joists for flooring and roofing;
k) Precast joists and trussed girders;
m) Light weight/cellular concrete slabs/wall panels;
n) Precast lintels and *Chajjas*;
p) Large panel prefabricates;
q) Reinforced/prestressed concrete trusses;
r) Reinforced/prestressed roof purlins;
s) Precast concrete L-panel units;
t) Prefabricated concrete double-T units;

u) Prefabricated sandwich concrete panels;

v) Precast concrete foundations; and

y) Precast concrete staircases.

Any other type of components shall be used with approval of the Competent Authority and appropriate testing.

Table 1 Precast Concrete (PC) Buildings with Different Structural Systems

(*Clause* 6.2.1.2)

Sl No. (1)	Structural System (2)
i)	*Building with Precast Concrete Moment Frames*:
	a) Buildings with single or multi-storey cantilever columns with simply supported beams (*see* Note 1)
	b) Building with ordinary moment resisting frames (OMRFs) (*see* Note 2)
	c) Buildings with special moment resisting frames (SMRFs)
ii)	*Buildings with Precast Concrete Structural Walls*:
	a) Ordinary structural walls (*see* Note 2)
	b) Ductile structural walls
iii)	*Buildings with Precast Concrete Moment Frames and Precast/RC Structural Walls* (*Dual System*) (*see* Note 3):
	a) Buildings with ordinary structural walls with OMRFs (*see* Note 2)
	b) Buildings with ordinary structural walls with SMRFs (*see* Note 2)
	c) Buildings with ductile structural walls with OMRFs (*see* Note 2)
	d) Buildings with ductile structural walls with SMRFs
iv)	*Precast Cell System*:
	a) Ordinary precast/RC structural wall system (*see* Note 2)
	b) Ductile precast/RC structural wall system

NOTES

1 Precast single-storey or multi-storey columns with simply supported beams shall be designed using a response reduction factor (R) of 2, as this system permits only one mode of plastic hinge formation.

2 Precast/RC emulative structures in Seismic Zones III and above shall be designed to be ductile. Hence, precast ordinary moment resisting frame system (OMRF) is not allowed in these seismic zones.

3 Buildings with precast RC structural walls also include buildings having precast RC structural walls and precast RC moment frames, but where:

a) frames are not designed to carry design lateral loads, or
b) frames are designed to carry design lateral loads, but do not fulfil the requirements of 'dual systems'.

4 Various types of moment resisting frame systems are explained in **6.3.4**, the structural designer shall select the appropriate system based on the requirements of the structure.

5 For all structures, precautions shall be taken to ensure continuity of load path, adequacy of connections, and compliance with drift limitations.

6 For shear walls with coupling beams, CIS coupling beams shall be used.

7 For elements designed to transfer gravity loads and not part of LFRS, assemblage testing shall be carried out to verify the failure mode of gravity frame elements and to ensure compliance with displacement requirements (equivalent to 'R' times the design storey drift), also the performance criteria with an approval from institute of repute may be verified.

8 The use of precast structural systems in Seismic Zone IV and above shall be permitted subject to approval by institute of repute. The adequacy of such systems shall be established through testing and/or appropriate structural analysis, as deemed appropriate.

6.3 Basic Precast Concrete Systems

Precast concrete building systems are composed of some basic types of structural systems. These systems shall be combined in various ways to obtain a suitable and effective structural concept that meets the needs of specific buildings. The most common systems are:

a) Precast concrete buildings with moment frames;

b) Precast concrete buildings with structural walls;

c) Precast concrete buildings with moment frames and structural walls (or dual system);

d) Precast concrete buildings with precast or cast-in-situ flat slab and precast concrete moment frames and precast concrete structural walls; and

e) Cell/3D system.

6.3.1 The above list is not unique as many combinations are possible to achieve the same objectives, such as the use of arches and rigid portal frames.

6.3.2 When facade systems act as load-bearing walls, their design shall explicitly consider lateral stability. For non-load-bearing facades, beam deflection and frame movement shall be accommodated in the connection detailing to avoid unintended cracking or overstressing of facade panels.

6.3.3 Where partial fixity is introduced by structural topping or dowels, the resulting flexural stiffness (EI) may be considered in serviceability limit state checks. The contribution of topping shall be analytically substantiated.

6.3.4 *Skeletal Frame Systems*

Skeletal frame systems composed of beams and columns shall be used where architectural flexibility, large spans, or column-free space is required, including in commercial, educational, healthcare and industrial facilities. The following skeletal systems shall be permitted:

a) Moment resisting frames; and

b) Moment frames with stabilizing cores (with precast structural walls).

Depending on the importance of the structure, structural framing system, connection detailing requirement and the level of ductility demanded by the building, the precast beam to column or beam to beam connection shall be selected from the five types as shown in Fig. 1. Type 1 and Type 2 (with minor fixity) shall be adopted with cantilever with single or multi-storey columns with simply supported beam. Types 2, 3 and 4 with detailing as per the good practice [C-7(2)] shall be adopted with OMRF. Types 2, 3, and 4 with detailing as per the good practice [C-7(1)] and detailing of connection as per this NBCS shall be adopted with SMRF. In the case of Type 3 and Type 4, the location of beam-to-beam connection shall be selected such that plastic hinge formation zones are avoided (at least more than 0.15 L_{beam}). In the case of secondary beams or short length beams, the location of the connection can be at the mid span with appropriate detailing.

6.3.4.1 *Moment resisting frames*

Rigid beam-column connections shall be formed using Type A, Type B, or Type C systems, depending on the required ductility level and building importance. All systems shall include structural topping for diaphragm action in accordance with 6.3.6:

a) *Type-A frames* — Type A frames shall consist of precast beam units between columns/column corbels, where columns can be cast-in-place or precast (*see* Fig. 2). These shall be achieved by adopting either one or a combination of the following arrangements:

  1) System A1 — This system consists of single or multi-storey columns fixed at the base, supporting simply supported beams on corbels or directly above the columns. The slab units shall be simply supported between the ledges or above the beams;

  2) System A2 — This system consists of single storey columns fixed at the base with provision of seating notch or temporary supports or permanent corbels for beams. Depending on design requirements, beams and slabs shall be designed as simply supported for temporary loading and made continuous for permanent loading;

  3) System A3 — This system consists of single or multi-storey columns fixed at the base and staggered joints between the columns at other grid levels with corbels to support the beams. Staggering of columns shall be arranged such that only 50 percent of all columns are spliced at any given storey level. Depending on design requirements, beams and slabs shall be designed as simply supported for temporary loading and made continuous for permanent loading; and

  4) System A4 — This system consists of 3 or 4 storeys columns fixed at the base with corbels to support the beams. Depending on design requirements, beams and slabs shall be designed as simply supported for temporary loading and made continuous for permanent loading.

FIG. 2 TYPE A FRAMES

b) *Type-B frames* — Type B frames shall consist of precast beam units passing through columns (*see* Fig. 3). These shall be achieved by adopting the following arrangement:

   1) System B1 — Columns shall be 1 storey high and spliced at each floor level. Precast beams run through the columns and are spliced at point of contraflexure. It shall be ensured that beam splices are avoided at end spans. Slab units shall be designed as simply supported.

FIG. 3 TYPE B FRAME

c) *Type-C frames* — Type C frames (*see* Fig. 4) shall consist of monolithically fabricated beam column units such as cruciform, T/L-units, H-frames, portal frames, etc. These shall be achieved by adopting either one or a combination of the following arrangements:

   1) System C1 — Single storey portal frames shall be placed alternately and simply supported at floor levels. Orthogonal beams and beams connecting the portal shall be simply supported or continuous based on the design requirements. Slab units shall be designed as simply supported; and

   2) System C2 — L-shaped and T-shaped frame units shall be placed simply supported on the base and on top of each other. Hinged or moment resisting connections shall be made between frame units at the mid-span of beams. Slab units shall be designed as simply supported.

3) System C3 — H-shaped frames with a cantilever beam shall be provided with rigid connection at the junction of beam and column. Hinge or moment resisting connections shall be provided at the mid-height of columns and centre of beams. Slab units shall be designed as simply supported.

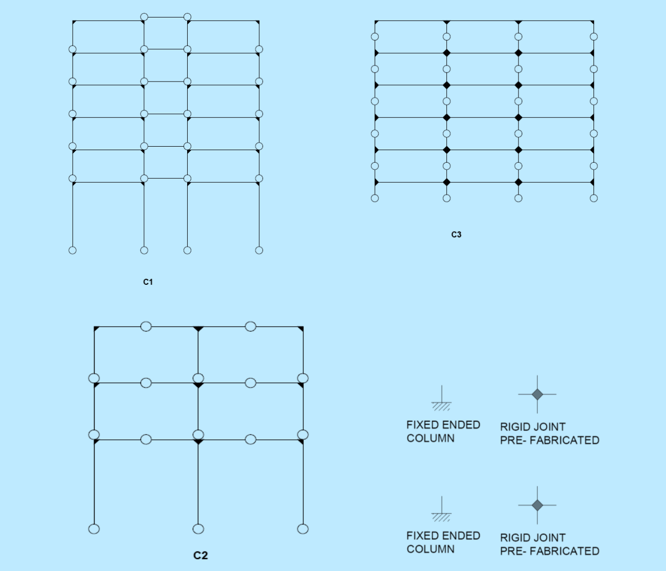

FIG. 4 TYPE C SYSTEMS

6.3.4.2 *Moment frames with structural wall*

In this system, lateral stability shall be achieved through structural walls, structural cores, or bracing. Beam-column and column-base connections shall be designed as pinned or rigid in accordance with the required ductility and seismic performance level (*see* Fig. 5).

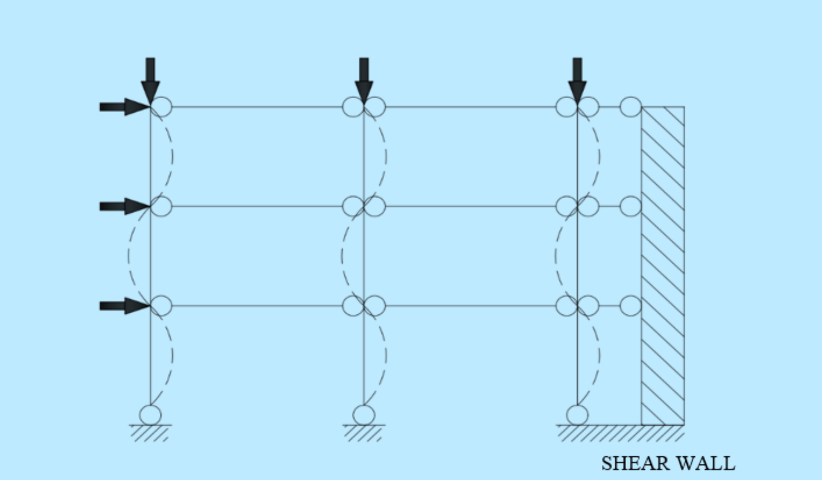

FIG. 5 DUAL SYSTEM

6.3.5 *Wall Systems*

Wall systems in precast construction shall be classified on the basis of the design of connections between individual concrete panels, which when joined together form the structural wall (*see* Fig. 6). The types of emulative wall systems shall be as follows:

a) Wall systems without shear transferring vertical joints; and

b) Monolithic wall systems.

These classifications shall guide the detailing of connections and the overall performance of the system under gravity and lateral loads.

6.3.5.1 For systems without shear transferring vertical joints, the horizontal joints shall be designed to exhibit ductile behaviour. Vertical joints shall not be relied upon for structural continuity and shall be detailed to allow for movement or minimal shear capacity to be provided. Each panel shall be designed as an independent unit for gravity and lateral loads.

6.3.5.2 For monolithic wall systems, horizontal joints shall be detailed to permit ductile behaviour. Vertical joints shall be designed as strong connections with sufficient capacity to remain elastic under design-level lateral loads, preserving global ductility.

6.3.5.3 For jointed wall systems, both vertical and horizontal joints shall be detailed to provide ductile behaviour. Connections shall be capable of undergoing inelastic deformation with energy dissipation, contributing to system-level ductility.

6.3.5.4 Combination of monolithic and systems without shear transferring vertical joints shall be adopted based on the performance requirements of the building.

MONOLITHIC SHEAR WALL

FIG. 6 SHEAR WALL BEHAVIOUR DUE TO CONNECTIONS

6.3.6 *Floor/Roof Systems*

Precast floor and roof systems shall be designed to function as horizontal diaphragms capable of transferring in-plane shear and distributing lateral loads to the lateral force resisting system (LFRS) under all applicable load combinations.

6.3.6.1 A minimum structural topping of 75 mm with reinforcing mesh or welded wire mesh shall be used in Seismic Zones III and above which can be reduced to 50 mm in Seismic Zone II. The diameter of re-bars used in both reinforcing mesh and welded wire mesh shall not be less than 6 mm. Welded wire mesh shall be avoided in Seismic Zones III and above. The minimum structural topping thickness shall be measured above the slab top level even at the highest camber location. Where service conduits of larger diameter are provided, the thickness of structural topping shall be such that a minimum cover of 25 mm is maintained above the conduit. The structural topping shall be provided on the entire floor.

6.3.6.2 Precast floor and roof systems shall be selected from the types defined in **6.3.6.3** to **6.3.6.6**, based on span length, loading and diaphragm requirements**.**

6.3.6.3 *Hollow-core slab* (*HCS*) *system*

This system is made up of prestressed precast concrete slabs with hollow cores (*see* Fig. 7). These systems may be used for multi-story buildings with moderate spans. Structural topping shall be provided to ensure diaphragm action. The top surface of the slab shall be intentionally roughened to amplitude more than 6 mm. The individual HCS units shall not be considered for diaphragm force transfer:

a) The thickness of hollow core slabs varies depending on the span and load requirements, but typically range from 150 mm to 500 mm;

b) Standard width of hollow core slab may be 1 200 mm or 2 400 mm; and

c) Standard dimensions of hollow core slabs shall conform to good practice [C-7(17)].

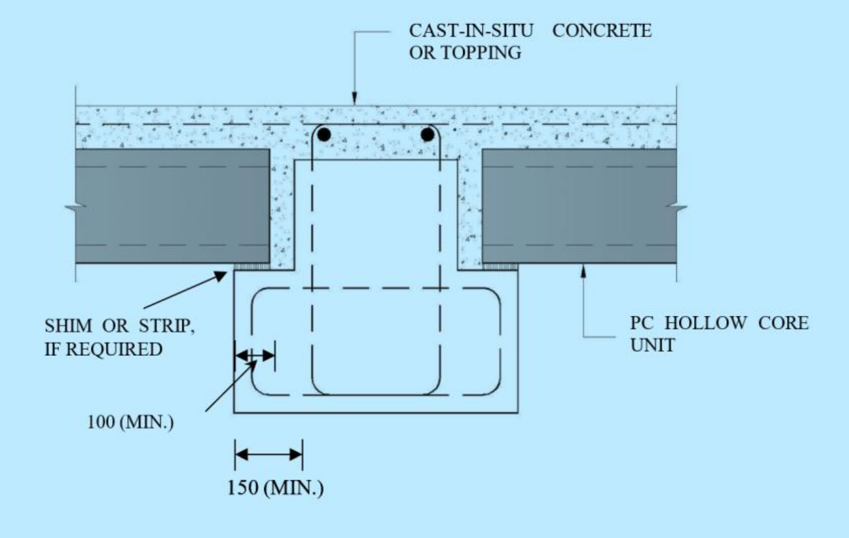

FIG. 7 HOLLOW CORE SLAB

6.3.6.4 *Double tee slab system*

This system is made up of precast concrete slabs with a double tee cross-section. The double tee shape provides greater strength and stiffness than a flat slab, making it suitable for larger spans and higher loads. These shall conform to good practice [C-7(17)]. Structural topping shall be provided to ensure diaphragm action. The double tee units shall not be considered in diaphragm action if the units are not connected for required force transfer, structural continuity and overall stability of the system.

6.3.6.5 *Solid slab system*

Solid precast concrete slab systems shall comprise precast elements that are thinner than equivalent hollow-core slabs. These slabs shall be used in residential or commercial buildings, where individual slab units are intended to span shorter distances.

The slab system shall be considered to act as a structural diaphragm when adequate connections are provided between the slab units and the supporting structural elements and when a structural topping concrete is placed and properly bonded.

In cases where no structural topping is provided, the slab system may still be designed to act as a diaphragm, provided that the connection details ensure adequate transfer of in-plane forces, structural continuity and overall stability of the system.

6.3.6.6 *One-way/two-way composite slab system*

6.3.6.6.1 Composite slab (*see* Fig. 8), also termed as half slab is a precast slab system cast in two stages. The first stage is to manufacture thin precast concrete panels, typically of about 60 mm to 85 mm thick, with the slab's bottom reinforcement and projected shear reinforcement in the form of truss. The projected reinforcement facilitates for multiple point lifting/handling as well as acts as shear connectors for in-situ deck concreting.

6.3.6.6.2 The slab panels shall be designed for overall thickness (precast and in-situ deck) as one-way or two-way in accordance with provisions of **5** of Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS, and Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS.

8C TYPICAL SECTIONAL VIEW

FIG. 8 PRECAST COMPOSITE SLAB PANELS

6.3.7 *Facade Systems*

Precast facade system shall be made up of following types of non-load bearing cladding panels:

a) Precast insulated concrete panels;

b) Precast solid cladding panels;

c) Architectural precast decorative facade panels; and

d) Precast concrete fins.

All façade connections shall comply with the requirements of the good practice [C-7(18)] and 6.3.2. Design shall account for differential movement, panel dead load and seismic restraint.

6.4 Hybrid System

The following systems are considered in precast hybrid system:

a) Precast concrete seismic structural system (PRESSS) (utilization of bonded or non-bonded prestressing tendons); and

b) Mixed system (utilization of cast-in-situ along with prestressed concrete (PC) members or steel members).

6.4.1 *Precast Concrete Seismic Structural System* (*PRESSS*)

Precast concrete seismic structural system (PRESSS) shall be implemented as an equivalent monolithic system, consisting of precast elements with grouted joints and bonded post-tensioned tendons. The main advantages of post-tensioning are deflection recovery and immediate occupancy of the structure. Two different system of PRESSS are explained in 6.4.1.1 and 6.4.1.2 and application of this system shall be carried out by conducting successful full-scale testing, verification through nonlinear analysis and approvals from competent authorities or institutes of repute.

6.4.1.1 *System* 1 *precast beam elements post-tensioned between columns*

System 1 shall use precast beams post-tensioned between multi-storey columns. Beam length shall be shorter than clear span (20 mm or tolerance requirements, whichever is greater). Post-tensioning and joint grouting shall occur after beam placement (*see* Fig. 9).

6.4.1.1.1 The beams shall be temporarily seated on steel brackets or props. Grout shall then be placed in the gap between beam ends and column faces, followed by post-tensioning operation and grouting of tendons.

6.4.1.1.2 The temporary supports shall be removed once the grout has achieved the required design strength.

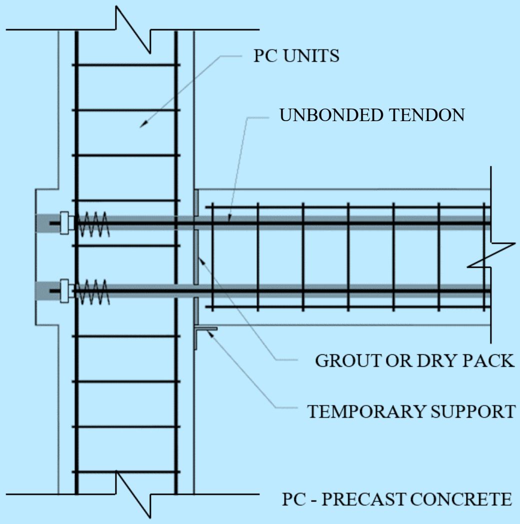

FIG. 9 SYSTEM 1 PRECAST BEAM ELEMENTS POST-TENSIONED BETWEEN COLUMNS

6.4.1.2 *System* 2 *supported precast beam elements post-tensioned between columns*

In this system, the beams shall be seated on corbels that transfer gravity loads to the adjacent columns. The beams shall be either built prismatic or with dapped ends, depending on the position of the corbel (*see* Fig. 10) and then post-tensioned.

6.4.1.2.1 The columns in this system shall normally be one-storey in height.

6.4.1.2.2 Columns shall be connected through a mechanical coupler or a grouted steel sleeve.

6.4.1.2.3 This system shall be adopted for buildings designed to demonstrate elastic response, with couplers giving continuity between the column elements, this is utilized for ductile moment resisting frames.

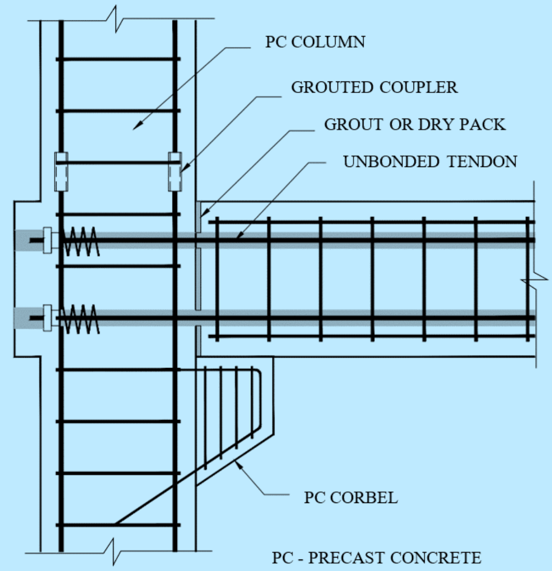

FIG. 10 SYSTEM 2 SUPPORTED PRECAST BEAM ELEMENTS POST-TENSIONED BETWEEN COLUMNS

6.4.2 *Mixed System* (*Cast In-Situ Precast or Structural Steel-Precast*)

This system shall use pretensioned prestressed concrete or reinforced concrete beam shell units or prestressed concrete beams as permanent formwork for cast in-situ beams or structural steel beams (as shown in Fig. 11). Application of this system shall be carried out by conducting successful full-scale testing, nonlinear analysis and approvals from competent authorities or institutes of repute.

6.4.2.1 The precast shells shall typically be left permanently in position after the cast-in-place reinforced concrete core has been cast. The shells can be made from fibre reinforced concrete or reinforced concrete, depending on the design requirements.

6.4.2.2 The precast U-beams or structural steel beams shall be designed to carry self-weight and construction loads and act compositely with the reinforced concrete core when subjected to other loading in the completed structure.

6.4.2.3 Precast U-beams may not be connected by reinforcement to the cast-in-place concrete of the beam or column. If the interfacial shear is found to be not sufficient then shear connector (protruding stirrups or ties) shall be provided between the interfaces.

6.4.2.4 The design shall ensure that the composite beams shall develop plastic hinges during major earthquakes.

6.4.2.5 All precast shell units shall be free of laitance, oil, dust and loose debris before placement of cast in-situ concrete. Construction sequences shall ensure adequate bond between interfaces.

6.5 Advanced Precast Systems

Advanced precast systems shall include modular 3D precast elements, digitally fabricated units and prefabricated structural modules integrated via design for manufacturing and assembly (DFMA) principles.

6.5.1 *3D Printed System*

3D printed precast systems shall only be used upon approval from the competent authority and shall follow Annex B for design, durability and testing criteria.

6.5.2 *Cell Systems*

Cell systems shall consist of volumetric precast units fabricated as open or closed modules. Connections to surrounding walls and floors shall be verified for strength and serviceability. Annex C shall be referred for further details.

Cell elements for specific area of a structure, such as wet zones (for example, toilets and kitchens), shall be used and integrated with wall and floor systems with appropriate connections.

6.6 Design for Manufacturing and Assembly (DFMA) Method

DFMA-based methods shall conform to Annex D. Designers shall ensure that precast elements are standardized, repeatable and modular to reduce rework and improve assembly efficiency.

7 STRUCTURAL ANALYSIS

7.1 General

Structural analysis shall be carried out to evaluate internal forces and deformations in members and the structural system. The analysis shall verify compliance with strength, serviceability, stability and robustness criteria. These effects include the distribution of forces and moments as well as the calculation of stresses, strains, curvatures, rotations and displacements under both static and dynamic conditions. Advanced analysis methods, such as nonlinear pushover analysis and time history analysis, may be adopted based on project requirements. However, these methods shall be mandatory for irregular structures, critical facilities and structures located in high seismic regions. For sustainable design aspects refer to **G-6**.

7.1.1 All the members and structural system shall be analysed to determine the critical load effects as per methods given in Part C 'Structural Design, Section 5 Structural Concrete' and relevant clauses of this Section.

7.1.2 To carry out analysis, the geometry, boundary conditions and behaviour of the structure need to be idealized both for global and local behaviour. The structure is idealized by considering it as made up of elements/ components which can be linear, two dimensional or three dimensional.

7.1.3 Structural analysis shall use methods capable of capturing action effects with sufficient accuracy. These may include classical mechanics or numerical methods such as finite element analysis, provided the model appropriately represents the actual structure.

7.1.4 Precast structures shall be analysed as either emulative systems, where precast performance matches that of monolithic CIS structures, or jointed systems with discrete joint behaviour. Emulative models shall assume monolithic behaviour with joints designed for equivalent force transfer. Lateral force resistance shall be achieved through moment-resisting joints or orthogonally placed structural walls or as per the design requirements.

7.1.5 For precast bearing wall buildings, rotational stiffness of floor-wall and floor-beam joints shall be neglected in structural design. Each component shall be independently designed considering the applicable end conditions, structural loads as specified in **7.2** and the various stages of construction.

7.1.6 Members shall also be designed to resist handling, erection and impact loads expected during the transportation and erection phases 7.14.

NOTES

1 Jointed construction using welded and bolted connections is not covered in this NBCS. This may be adopted with approval from competent authority and appropriate testing.

2 Rotational stiffness may be accounted for long/short term deflection and serviceability calculations as per 6.3.4, provided that the approach is mutually agreed by the design team and approved by the Authority.

3 Horizontal precast members that transfer gravity loads but are not part of the lateral force resisting system (LFRS) shall be designed assuming pinned end conditions, unless justified otherwise through analysis.

4 Linear model, non-linear model and P-Delta analyses may be used for design, provided the analysis method, assumptions and modelling parameters are clearly defined and justified and approved by the Competent Authority.

7.2 Loads and Forces

The design shall consider all the loading requirements as specified in Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS. Consideration shall also be given to construction loads, any special requirements, such as for plant loads or storage loads and the loading condition should be modified accordingly.

7.2.1 Structural design shall take into consideration the dead loads, live or imposed loads, wind loads, forces such as those caused by earthquake effects, prestressing effects, crane loads, vibration, impact, natural disasters (flood, landslide, etc), blast and effects due to shrinkage, creep, temperature, etc, where applicable.

7.2.1.1 *Dead load*

Dead loads shall be calculated based on unit weights which shall be established taking into consideration the materials specified for construction or **2** of Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS.

7.2.1.2 *Imposed load*

Imposed loads shall be considered as per **3** of Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS. A minimum construction load (as per design requirement) of 1.0 kN/m^2 or construction traffic load shall be adopted for design, if not specified in the contract document. However, due consideration shall be given to actual possible construction loads.

7.2.1.3 *Wind load*

Wind load shall be considered as per **4** of Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS.

7.2.1.4 *Construction traffic load*

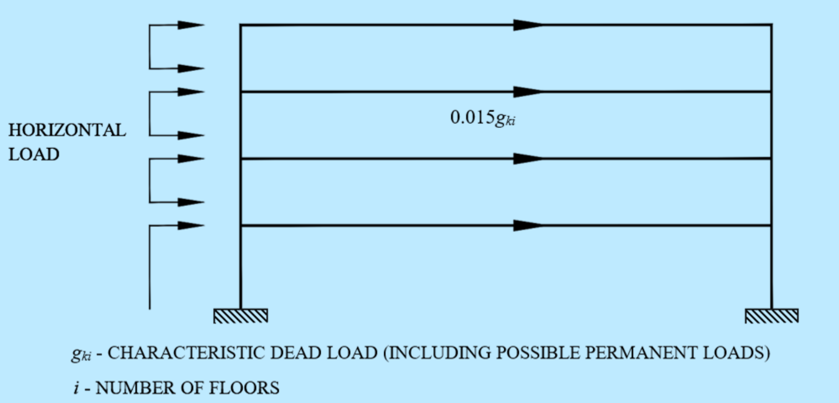
Construction traffic load shall be assumed in accordance with the project requirements. A minimum traffic load (as per design requirement) of 1.0 kN/m^2 or imposed load shall be adopted for design, if not specified in the contract document.

7.2.1.5 *Seismic load*

The seismic forces shall be calculated in accordance with **5** of Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS.

7.2.1.6 *Notional horizontal load*

Notional horizontal load (as shown in Fig. 12) shall be taken as not less than 1.5 percent of the characteristic dead load and accidental loads such as from earth movement, impact of construction vehicles, etc.



HORIZONTAL LOAD
$0.015g_{ki}$
g_{ki} - CHARACTERISTIC DEAD LOAD (INCLUDING POSSIBLE PERMANENT LOADS)
i - NUMBER OF FLOORS

Fig. 12 Notional Horizontal Load Floor Levels

7.2.1.7 *Shrinkage, creep and temperature effects*

The effects of shrinkage, creep and temperature shall be considered according to the good practice [C-7(2)]. Special literature can be referred to for critical structures.

7.2.1.8 *Environmental loading*

The effects of thermal loading and changes in values of creep and shrinkage due to environmental exposure shall be considered according to the good practice [C-7(2)] or as defined in design basis report.

7.2.1.9 *Other forces and effects*

Relevant clauses of Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS shall be followed for additional forces such as snow load, liquid retaining loads, impact due to equipment, cranes, etc.

7.2.2 *Load Combinations*

Basic load combination shall be as per the good practice [C-7(2)] and Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS. In addition, precast specific load combinations specified by the competent authority or given in this NBCS shall be adopted.

7.2.2.1 *Factor of safety/partial safety factor for load combinations*

Load and material safety factors shall be as per the good practice [C-7(2)]. Precast specific partial safety factors given at various sections of this NBCS shall be adopted accordingly.

7.3 Effective Span

7.3.1 Except for the purely simply supported spans, the effective spans for all elements shall be estimated as per the relevant clauses of the good practice [C-7(2)].

7.3.2 Effective span for all elements during the temporary erection stage are to be considered based on the temporary support condition.

7.3.3 The effective span for simply supported elements shall be considered as the centre-to-centre distance between the bearing pads or shims at each end. If the multiple shims are used, only the shims or pads close to the end of the elements shall be considered as governing case.

7.4 Stiffness

7.4.1 *Relative Stiffness*

The relative stiffness of the member shall be calculated based on the moment of inertia of the section considering gross section, transformed section and cracked section as provided in the good practice [C-7(2)].

7.4.2 *Stiffness Modifiers*

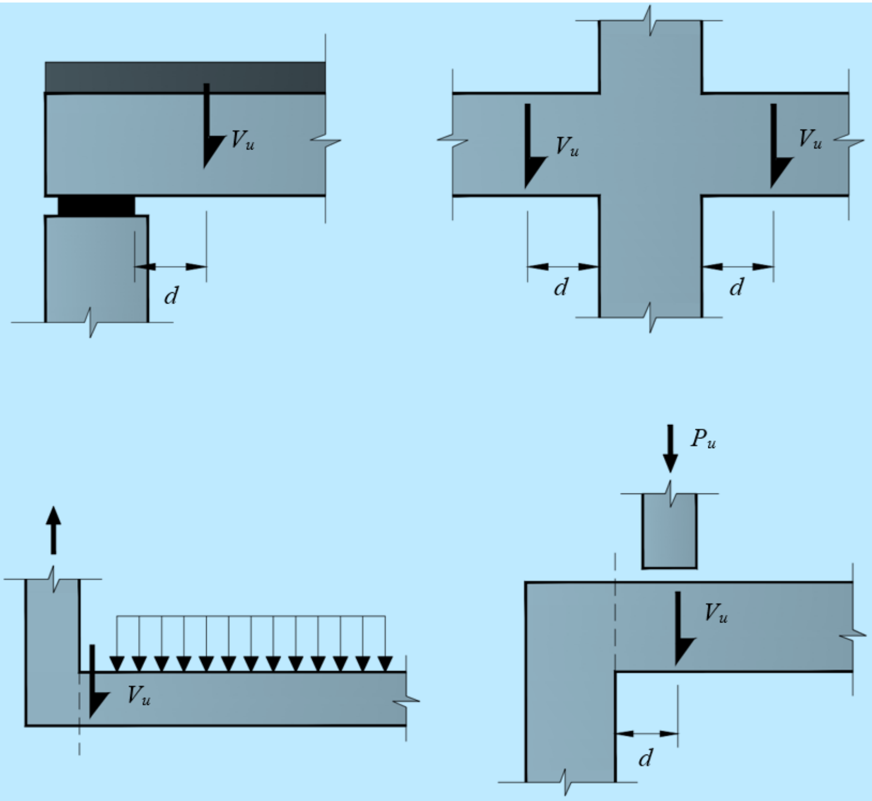
Stiffness reduction factors for members and connections shall be applied as per **5** of Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS, considering structural system type and ductility requirements.

7.4.3 *Critical Sections for Moment and Shear*

The critical sections for moment and shear shall be identified as per the good practice [C-7(2)] and additionally as per **7.4.3.1** and **7.4.3.2**.

7.4.3.1 Critical section for shear as per the good practice [C-7(2)] is shown in Fig. 13.

7.4.3.2 For L-beams and inverted T-beams carrying loads within the bottom 30 percent of section depth (*refer* Fig. 13), the critical section for shear shall be taken at the face of support, unless a monolithic or emulative beam-column joint is specifically detailed to resist shear.



d – effective depth of beam

FIG. 13 CRITICAL SECTION FOR SHEAR

7.5 Concentrated Loads on Floor Slabs

7.5.1 Concentrated loads shall be applied as per Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS. Effective width for slabs carrying concentrated loads shall be calculated as per the good practice [C-7(2)] along with **7.5.2** and **7.5.3**.

7.5.2 The load distribution for hollow core slab depends on the one-way action of the plank and the cast in place structural topping. The effective width for hollow core slabs shall be calculated as per **7.5.3**.

7.5.3 Moments and shears induced by line and concentrated loads shall be resisted by an effective section as described in Fig. 14. If the total deck width, perpendicular to the span, is less than the span, modification may be required. In addition, the following limitations would apply:

a) As the width of the system becomes narrower than the span length, the effective resisting widths will become narrower;

b) For extremely high span-depth ratios (more than approximately 50), the effective section at mid-span shall be reduced by 10 percent to 20 percent;

c) For spans less than about 3 m, the effective width at the support may become narrower; and

d) Local load concentrations can cause longitudinal splitting failures due to transverse bending in the system and punching shear failure. The magnitude of concentrated loads shall be limited to minimise such failures.

FIG. 14 MOMENT AND SHEAR DISTRIBUTION WIDTHS FOR HCS

7.6 Stability Design

7.6.1 *Design Philosophy*

The following factors shall be considered in designing for stability of a precast structure:

a) The overall structural system shall be checked for global and local stability under all applicable loading conditions including temporary and final stages;

b) Precast structural systems shall be designed to resist wind and all applicable lateral loads;

c) Cross walls or sway frames shall be so arranged to provide lateral stability;

d) When lateral loads are low, stability shall be verified using a notional horizontal force equal to 1.5 percent of total vertical load, as shown in Fig. 12;

e) Lateral stability shall be maintained during all construction and erection stages. Temporary bracing, shoring, or props shall be detailed and installed to match the staged loading conditions. A temporary works scheme including propping layout, sequencing and dismantling plan shall be submitted and approved before execution;

f) Inverted T and L-beams shall be analysed for asymmetric loading during both construction and service stages, using all applicable load combinations;

g) The strength of grout shall be at least 50 percent of the design strength or as per design requirement before application of any other loads (temporary or permanent) on the element. Stress and cracking shall be evaluated and verified before proceeding;

h) Long-span and high-rise precast structures shall include engineered bracing and verified stability measures during all construction and service stages; and

j) Temporary anchors shall be designed for proper alignment and safety of the elements. Appropriate washers shall be used.

7.6.1.1 *Overturning*

Stability against overturning shall be checked in accordance with the requirements in Part C/Section 5 of this NBCS. For L and inverted T beams, lateral support shall be provided during construction to avoid stability related failures.

7.6.1.2 *Sliding*

Stability against sliding shall be checked in accordance with the requirements in the good practice [C-7(2)]. All the precast members during construction shall be propped or anchored to prevent sliding from the supporting structure. Minimum bearing as per 7.11 shall be followed.

7.6.1.3 *Probable variation in dead load*

Probable variations in dead load during casting of in-situ components shall be accounted for in the design. Pouring of structural topping above the long span elements (such as HCS) shall be monitored to have the required pouring depth measured from top of the highest point of the element (camber point) instead of global level.

7.6.1.4 *Moment connection*

Moment connection shall be used for lateral force resistance system frames. Where frames are pin-jointed, transverse stability shall be ensured through structural walls or bracing system. Integrity ties shall be provided to maintain system continuity.

7.6.1.5 *Lateral sway*

Stability against lateral sway shall be evaluated using the good practice [C-7(2)] and **5** of Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS, including during temporary construction stages and final occupancy.

7.6.1.6 *Lateral force resistance system design*

The lateral force resistance system design shall be in accordance with the relevant provisions of Part C 'Structural Design, Section 1 Loads and Load Effects', Part C 'Structural Design, Section 5 Structural Concrete' and Part C 'Structural Design, Section 6 Steel and Steel-Concrete Composite Construction, Subsection A Steel' of this NBCS with the guidelines stipulated in **6**. Additional impact of lateral loads such as earth fill, or liquid/snow retention shall be analysed as per the project requirements.

7.7 Durability Design

7.7.1 *Design Philosophy*

The following factors shall be considered for achieving the design life and durability of a precast structure:

a) Geometry and detailing of precast elements;

b) Concrete mix design, including constituent materials;

c) Nominal and minimum cover as per environmental class;

d) Environmental exposure classification in accordance with the good practice [C-7(2)];

e) Fire resistance rating based on intended use;

f) Access provisions for inspection and maintenance;

g) Controlled production quality;

h) Handling, transport and erection constraints; and

j) Watertight and durable joint detailing.

In addition to above requirements, the recommendations specified in the good practice [C-7(2)] and relevant accepted standards shall be followed.

7.7.2 *Service Life*

7.7.2.1 The service life of any structure shall be specified in the design basis report (DBR) or considered based on the good practice [C-7(2)].

7.7.2.2 For temporary structure, the service life shall be considered as the period the structure is required to satisfy the intended function, or as mentioned in the contract document.

7.7.2.3 The service life specified for a structure does not apply to architectural finishes, replaceable materials such as sealants, paints, non-structural grout. The service life of such items shall be considered as per the manufacturer's guidelines and mutually agreed upon by all the stakeholders.

7.7.3 *Shape of Precast Units*

7.7.3.1 Sharp corners or sudden changes in geometry, re-entrant corners, or grooves in a section causes stress concentrations that may lead to cracking or spalling of concrete and therefore shall be avoided. For sections with practical constraints, stress concentrations shall be checked and strengthening or local detailing shall be provided, as necessary.

7.7.3.2 Extra reinforcements shall be provided around the cut-outs or opening, if any, present in an element. Larger cut-outs shall be considered in the analysis to characterize the stress concentration and its effects on the design as per the good practice [C-7(2)].

7.7.3.3 Buckling and instability must be prevented during the lifting and erection of long, slender precast units, as per the good practice [C-7(2)]. For thin sections (thickness less than 75 mm), the positioning of lifting inserts should be such that it prevents buckling of the compression flange, especially during the handling and manoeuvring of the elements.

7.7.3.4 The precast unit shall be designed and detailed to have sufficient drainage to avoid standing water or excessive moisture.

7.7.4 *Concrete Cover*

Concrete cover for precast concrete elements shall comply with the requirements of the good practice [C-7(2)], unless reduced values from Table 2 are adopted. Reduced cover values shall only be permitted if the elements are produced in a controlled environment.

7.7.4.1 The minimum concrete cover for reinforcement to ensure durability against fire and corrosion shall comply with the provision of the good practice [C-7(2)]. Fire resistance of joint fillers and other components shall meet or exceed the fire resistance rating of the connected precast members, or as prescribed in **7.8**.

7.7.4.2 The cover to all brackets, fixings, etc shall comply with the minimum cover requirements specified for reinforcement as per the above table or the good practice [C-7(2)].

Table 2 Nominal Cover in Precast Elements

(*Clause* 7.7.4)

Sl No.	**Exposure**	**Elements**	**Nominal Concrete Cover,** (mm, *Min*)
(1)	(2)	(3)	(4)
i)	Mild	All	20
ii)	Moderate	Slabs and walls	25
		For the ties/stirrups of beams and columns exposed to weather	25
		For ties/stirrups of beams and columns non-exposed to weather	Greater of d_b or 20
iii)	Severe	All	40
iv)	Very Severe	All	45
v)	Extreme	All	70

NOTES

1 The prescribed covers for precast elements are lesser than the covers noted in the good practice [C-7(2)] to account for the greater control for proportioning, placing and curing inherent to precast concrete produced in a controlled environment.

2 Controlled environment does not imply that the precast members shall be manufactured in a factory. Elements manufactured at the jobsite or in a temporary factory also qualify under these requirements, if the controls are equal to that normally adopted in a factory. The client and engineer-in-charge shall verify the temporary factory and certify the same, if the cover requirements of this Table are adopted.

3 d_b is bar diameter.

7.7.5 *Protection and Maintenance of Joints and Connections*

7.7.5.1 The connection between the precast element shall be properly filled with high strength, non-shrink, non-metallic cementitious grout (minimum 50 MPa or 5 MPa more than the strength of the element, whichever higher) to prevent corrosion, cracking and spalling of concrete. Where the joint gap between the precast elements is more than 50 mm, the provisions of **5.4.1.3** shall apply.

7.7.5.2 Steel plates or inserts used in permanent connections shall be provided with adequate concrete cover or protected with corrosion-resistant coatings. Inserts for temporary use shall be removed or treated to prevent corrosion.

7.7.5.3 Where minimum cover cannot be ensured due to geometric or project constraints, only corrosion-resistant materials (such as stainless steel or galvanized steel) shall be used for connectors and fixings.

7.7.6 *Other Effects*

7.7.6.1 Joint spacing and width shall account for cumulative movements including production tolerances, creep, shrinkage, settlement and thermal expansion to prevent cracking and spalling.

7.7.6.2 In addition to satisfying general requirements for durability, strength, stability, control of cracking and limitation of deformation, the following provisions shall be met:

a) Structural components shall be designed to limit cracking and deformation from early thermal movements, creep and shrinkage; and

b) Bearings or movement joints shall be provided to minimize structural restraints. Where restraint is unavoidable, the design shall include measures to resist resulting stresses, with reinforcement provided as per as per the good practice [C-7(2)].

7.8 Fire Resistance

7.8.1 *Fire Resistance Requirement*

7.8.1.1 The fire resistance of a structural element shall be expressed in terms of time in hours in accordance with good practices [C-7(19)]. General requirements for fire protection are given in good practice Part F 'Fire and Life Safety' of this NBCS.

7.8.1.2 Elements and joints wider than 50 mm shall comply with fire resistance provisions of the good practice [C-7(2)], except where otherwise specified in this section.

7.8.1.3 All joints in fire-prone structures shall be filled with mortar, grout, or concrete in accordance with the design requirements.

7.8.1.4 The joints between slab elements or hollow core elements with structural topping of more than 50 mm (minimum thickness of structural topping concrete) may not require any additional treatment for fire rating.

7.8.1.5 For joints between structural wall elements with a width less than or equal to 50 mm shall be filled with grout of strength minimum 50 MPa or 5 MPa more than the strength of the element, whichever higher. For non-structural wall elements, the grout strength shall be at least equal to that of the element. For joints with a width exceeding 50 mm, the provisions of **5.4.1.3** shall apply.

7.9 Structural Design of Precast Concrete Components

7.9.1 *Footings*

7.9.1.1 All the design and detailing requirements of the good practice [C-7(2)] shall be followed for members/elements along with any specific criteria given in this Section.

7.9.1.2 Precast footing with multiple elements stitched using appropriate connection arrangement shall be adopted, wherever required. However, footing subjected to vibration shall be without any joints, preferably a single unit or cast in-situ or the system shall be tested prior to application for the required level of vibration.

7.9.1.3 The minimum thickness at the edge of a precast footing shall be as per the good practice [C-7(2)].

7.9.1.4 The connections shall be detailed as per **8** to ensure effective force transfer between elements.

7.9.1.5 Detailing of column, pedestal and wall connections to the footing elements shall be as per **8**.

7.9.2 *Walls*

7.9.2.1 Design and detailing of wall elements shall comply with the good practice [C-7(2)], in addition to the specific requirements of this Section.

7.9.2.2 As the elements are manufactured in controlled environment, walls subjected to marginal shear forces, minimum longitudinal and transverse reinforcement shall be 0.1 percent of gross area. For other cases, reinforcement shall be as per the good practice [C-7(2)].

7.9.2.3 The connections shall be detailed as per **8** and shall ensure proper force transfer between the elements.

7.9.2.4 Walls shall be tied to intersecting elements such as floors, columns, other walls and footings using appropriate ties or mechanical connections that ensure force transfer and structural continuity.

7.9.3 *Shear Wall*

7.9.3.1 All the design and detailing requirements of the good practice [C-7(2)] shall be followed for members/elements along with any specific criteria given in this Section.

7.9.3.2 Minimum reinforcement for structural wall shall be as per the good practice [C-7(2)] and as per good practice [C-7(18)].

7.9.3.3 At least one continuous vertical tie of 12 mm diameter or higher shall be provided from foundation to terrace at each end of the structural wall using Class H coupler as per [C-7(9)] or any other connection with appropriate lapping or welding as per the design requirements.

7.9.3.4 The connections shall be detailed as per **8** and to ensure adequate transfer of axial, shear and bending forces between connected elements.

7.9.3.5 Shear walls shall be structurally tied to intersecting elements, including floors, columns, other walls and footings, using mechanical ties, dowels, or other engineered connections capable of transferring expected design loads.

7.9.4 *Floors/Slabs*

7.9.4.1 All the design and detailing requirements of the good practice of [C-7(1)] shall be followed for members/ elements along with any specific criteria given in this Section.

7.9.4.2 Minimum reinforcement for slab elements and structural topping the minimum reinforcement shall be as per good practice [C-7(1)].

7.9.4.3 The thickness of structural topping shall be considered if the maximum shear stress at any location is less than 0.4 MPa. Also, the top surface of the slab shall be roughened to a minimum amplitude of 6 mm. Where the shear stress exceeds 0.4 MPa, adequate shear reinforcement or studs shall be provided to ensures the composite action between the topping and the floor slab elements.

7.9.4.4 The minimum grade of concrete for the structural topping shall be equal to M30 or as per design (whichever is higher).

7.9.4.5 The connections shall be detailed as per **8** and shall ensure proper force transfer between the elements.

7.9.4.6 For pre-tensioned and post-tensioned members, stress limits shall be as per good practice [C-7(3)].

7.9.4.7 For simply supported slab at least one third of the maximum positive reinforcement shall be extended till the centre of the bearing. For other cases, at least one fourth of the reinforcement shall extend into the support for a length of 150 mm. Adequate development length shall be provided to the bottom reinforcement as per good practice [C-7(2)]

7.9.4.8 For requirements relating to design and detailing for precast structures with hollow core slabs, Annex H may be referred.

7.9.5 *Columns*

7.9.5.1 All the design and detailing requirements of the good practice [C-7(1)] shall be followed for members/elements along with any specific criteria given in this NBCS.

7.9.5.2 Minimum reinforcement requirements shall be as per the good practice [C-7(2)].

7.9.5.3 The connections shall be detailed as per **8** and shall ensure proper force transfer between the elements.

7.9.5.4 At least four continuous vertical ties of 12 mm diameter or higher shall be provided from foundation till the roof using Class H coupler as per accepted standard [C-7(9)] or any other connection, with appropriate lapping or welding.

7.9.5.5 Transverse reinforcement as per the good practice [C-7(2)] shall be provided in the members as well as the splice locations (grouted coupler, grouted duct, mechanical connections, etc).

7.9.5.6 For connection using grouted coupler of height less than 250 mm, minimum cover to the confinement reinforcement shall be 25 mm at the location of coupler. For all other cases cover shall be as per the good practice [C-7(2)].

7.9.5.6 For connection using grouted duct/tube or any other, minimum cover shall be as per the good practice [C-7(2)].

7.9.6 *Beams*

7.9.6.1 All the design and detailing requirements of good practice [C-7(1)], [C-7 (2)] and [C-7(3)] shall be followed for members/elements along with any specific criteria given in this Section.

7.9.6.2 Minimum reinforcement requirements shall be as per the good practice [C-7(2)].

7.9.6.3 The connections shall be detailed as per **8** and shall ensure proper force transfer between the elements.

7.9.6.4 Transverse reinforcement as per good practice [C-7(2)] shall be provided in the members as well as the splice locations (grouted coupler, grouted duct, mechanical connections, etc).

7.9.6.5 For connection using mechanical coupler of length less than 500 mm, minimum cover of 20 mm shall be maintained to the transverse reinforcement at the coupler location. In all other cases the cover shall be as per the good practice [C-7(2)].

7.9.6.6 For beam made composite to the cast in-situ topping (T-action or L-action, in compression), the thickness of cast in-situ shall be considered in the height of the beam and the width of flange shall be calculated according to the good practice [C-7(2)].

7.9.6.7 Stress limits for pre-tensioned and post-tensioned beams shall be as per good practice [C-7(3)].

7.9.6.8 For simply supported beam at least one third of the maximum positive reinforcement shall be extended till the centre of the bearing. For other cases, the reinforcement shall extend to the other member or to the support and shall develop f_y at the tension face of the support.

7.9.7 *Staircase/Landing*

7.9.7.1 All the design and detailing requirements of Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS shall be followed for members along with any specific criteria given in this Section.

7.9.7.2 Minimum reinforcement requirements shall be as per Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS and shall ensure proper force transfer between the elements.

7.9.7.3 The connections shall be detailed as per **8**.

7.9.8 *Composite Concrete Construction*

7.9.8.1 All the design and detailing requirements of Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS shall be followed for members along with any specific criteria given in this Section.

7.9.8.2 The connections shall be detailed as per **8** and shall ensure proper force transfer between the elements.

7.9.9 *Insulated Panels/Thermal Comfort*

7.9.9.1 All the design and detailing requirements of Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS shall be followed for members along with any specific criteria given in this Section.

7.9.9.2 Minimum thickness of the concrete wythe shall be 50 mm.

7.9.9.3 Individual wythe shall be connected to each using wythe connectors by providing solid zones or special reinforcements.

7.9.9.4 Maximum spacing between the reinforcements in the wythe shall be 250 mm or as per design.

7.9.9.5 For walls made from composite wythe, the solid zone shall be designed to transfer the shear demand on the wall and for moment transfer complete composite wythe section shall be considered.

7.9.9.6 Insulation material if provided shall have adequate bond with the concrete wythes to avoid splitting of junction during handling.

7.9.9.7 The connections with other elements shall be detailed as per **8** and shall ensure proper force transfer between the elements.

7.9.10 *Composite Floors*

7.9.10.1 All the design and detailing requirements of Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS shall be followed for members along with any specific criteria given in this Section.

7.9.10.2 No shear reinforcement/studs shall be provided if the maximum shear stress at any location is less than or equal to 0.4 MPa.

7.9.10.3 The minimum grade of concrete for the structural topping shall be equal to M30 or as per design (whichever is higher).

7.9.10.4 The connections shall be detailed as per **8** and shall ensure proper force transfer between the elements.

7.9.11 *Others Structural Elements*

7.9.11.1 Any structural element shall be designed and detailed as per Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS.

7.9.11.2 The connections shall be detailed as per **8** and shall ensure proper force transfer between the elements.

7.9.11.3 Any connection scheme found effective in force transfer shall be used, subjected to approval of competent authority.

7.10 *Design of Diaphragm*

For the stability of the precast concrete building horizontal loads due to wind and earthquake shall be transmitted to the lateral force resistance system through the floor acting as horizontal deep beam. However, in a precast slab system, the floor comprises individual units generally not connected to each other. A structural topping concrete is provided to act as the diaphragm, or the individual elements are connected. In this system, the diaphragm action shall ensure the following:

a) Collect and transfer lateral forces at each level to the lateral force resisting elements such as shear walls, moment frames, etc; and

b) Tie individual lateral force resisting elements into a single lateral force resisting system.

7.10.1 Diaphragm action arises from the in-plane stiffness inherent to the floor system. As a result, substantial in-plane forces can develop in the diaphragm during lateral loading. In the context of precast concrete construction, the panelled nature of floor systems can pose challenges in the seismic design of diaphragms. These challenges may involve ensuring sufficient strength, stiffness, and in some cases, ductility in both the diaphragm and its connections.

7.10.2 In case of buildings whose floors can provide rigid horizontal diaphragm action, the total shear in any horizontal plane shall be distributed to the various vertical elements of lateral forces resisting system, assuming the floors to be infinitely rigid in the horizontal plane.

7.10.3 In case of building whose floor diaphragms cannot be treated as infinitely rigid in their own plane, the lateral shear at each floor shall be distributed to the vertical elements resisting the lateral forces, considering the in-plane flexibility of the diaphragms.

> NOTE — Reinforced concrete monolithic slab-beam floors or those consisting of prefabricated/precast elements such as solid slabs, hollow core slabs or double tees with reinforced topping shall satisfy the requirements of 7.10.10. In all cases, the precast elements need not be considered as part of the diaphragm except solid slabs with proper connectivity. The gravity load design, however, shall be composite including the structural topping as well as the precast element provided the interface shear at the topping and element face is analysed and designed for the same.

7.10.4 *Rigid Diaphragms*

A diaphragm is classified as rigid if it can distribute the horizontal forces to the vertical components in proportion to their relative stiffness. Diaphragms of concrete slabs of concrete-filled metal deck with span-to-depth ratios of 3 or less in structures that have no horizontal irregularities are permitted to be idealized as rigid. The minimum thickness of structural topping concrete shall be as per 7.10.10.

Where the diaphragm is very stiff compared to the vertical elements, as in a low aspect ratio, cast-in-place diaphragm supported by moment frames, it is acceptable to model the diaphragm as a completely rigid element.

7.10.5 *Flexible Diaphragms*

A floor diaphragm shall be considered to be flexible, if it deforms such that the maximum lateral displacement measured from the chord of the deformed shape at any point of the diaphragm is more than 1.5 times the average displacement of the entire diaphragm or as per good practice [C-7(18)] and **5** of Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS. Flexible diaphragm can be adopted in modular structures having frequent openings such as substation, electrical rooms, industrial structures, etc.

7.10.5.1 Where the diaphragm is flexible compared with the vertical elements, as in some jointed precast systems supported by structural walls, it may be acceptable to model the diaphragm as a flexible beam spanning between rigid supports.

7.10.5.2 In other cases, it may be advisable to adopt a more detailed analytical model to account for the effects of diaphragm flexibility on the distribution of displacements and forces. Examples include buildings in which diaphragm and vertical element stiffness have approximately the same value, buildings with large force transfers, and parking structures in which ramps connect between floors and act essentially as bracing elements within the building.

7.10.6 *Topped Diaphragms*

Topped floor and roof diaphragms include systems with in-situ concrete slab over precast RC planks and joists. The in-situ concrete slab is considered to act composite with the precast RC planks with sufficient surface roughness to transfer horizontal shear, so that the flexural strength of the precast component is enhanced by the added structural depth of the in-situ slab.

> NOTE — In the computational model of the structure, the diaphragm shall be modelled considering the thickness of the topping/structural topping with extra dead load applied on top of the diaphragm to consider the precast planks or elements.

7.10.7 *In-plane Diaphragm Design Loads and Forces*

Topped floor and roof diaphragms shall be designed to resist design in-plane inertial forces due to earthquake forces and wind loads from the structural analysis. Earthquake forces shall be calculated in accordance with good practices [C-7(1)] and [C-7(20)] and **5** of Part C 'Structural design/Section 1 Loads and load effects' of this NBCS. Wind loads shall be estimated in accordance with Part C 'Structural design/Section 1 Loads and load effects' of this NBCS.

7.10.8 *Standard Analysis Methods for Diaphragm Design*

7.10.8.1 The magnitude of the inertia force at each floor level is estimated using a capacity design approach or a diaphragm design force distribution based on equivalent lateral loads. A key design step is to transform the diaphragm design forces into internal actions. For regular floor plans, a 'horizontal plate girder' analogy is typically used in design. In this approach, diaphragm design forces are typically applied at each level as a distributed in-plane load along the length of the diaphragm. The resulting girder internal forces are used to determine the amount of flexural reinforcement (chord steel), shear (web) reinforcement, and lateral system reaction load path reinforcement (collector steel). An irregular mass distribution in plan may require the design forces to take on a smeared load configuration as the mass distribution with respect to diaphragm depth has relevance in determining the proper web reinforcement. For more complex diaphragm configurations, a strut-and-tie method can be used. The strut-and-tie method accurately predicts the behaviour of floor diaphragms, in general, and may become the preferred method of diaphragm analysis (*see* Fig. 15 and Fig. 16).

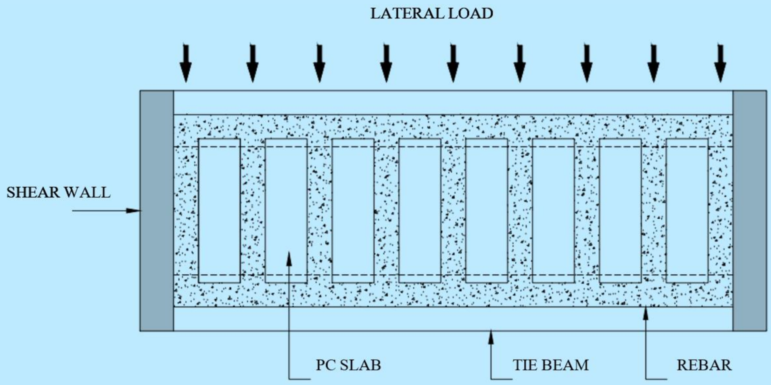
7.10.8.2 Calculation of diaphragm in-plane design moments, shears and axial forces shall be consistent with requirements of equilibrium and with design boundary conditions. It shall be permitted to calculate design moments, shears, and axial forces in accordance with one of (a) through (d):

a) A rigid diaphragm model if the diaphragm can be idealized as rigid;

b) A flexible diaphragm model if the diaphragm can be idealized as flexible;

c) A bounding analysis in which the design values are the envelope of values obtained by assuming upper bound and lower bound in-plane stiffness for the diaphragm in two or more separate analyses; and

d) A finite element model considering diaphragm flexibility (semi rigid).



15A DIAGONAL TRUSS

15C DEEP HORIZONTAL BEAM

FIG. 15 STRUCTURAL MODELS FOR FLOOR DIAPHRAGMS

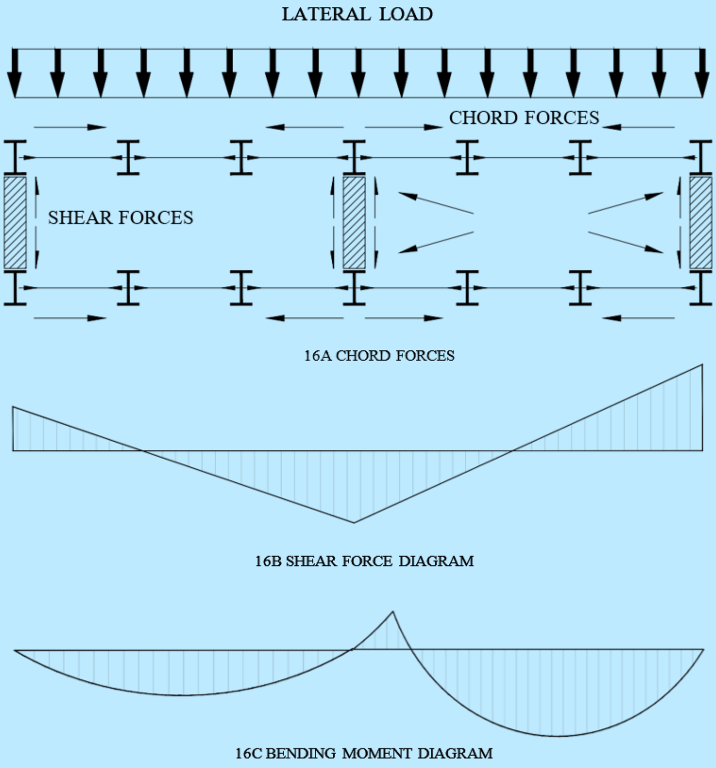

FIG. 16 DESIGN FORCES ON A DIAPHRAGM

7.10.9 *Materials*

7.10.9.1 Design properties of in-situ concrete for the topped diaphragms and diaphragm reinforcement shall be considered as per Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS.

7.10.9.2 Minimum grade of structural topping concrete shall be 40 MPa or as per design (whichever is higher).

7.10.10 *Minimum thickness of topped diaphragms*

7.10.10.1 Topped floor and roof diaphragms shall have thickness as required for stability, strength and stiffness under factored load combinations.

7.10.10.2 Topped floor and roof diaphragms that comprises RC planks composite with in-situ concrete slabs, the full thickness of the entire diaphragm must be sufficient to resist the design actions. In system with special precast slab elements such as hollow core slabs or double tees, the diaphragm thickness shall be limited to the in-situ structural topping concrete.

7.10.10.3 The minimum thickness of in-situ structural topping concrete shall be as per 6.3.6.1.

7.10.11 *Diaphragm Connections*

Connections between individual precast RC planks shall not be designed for any diaphragm forces in a topped diaphragm where the diaphragm thickness is limited to cast-in-place structural topping only. Nominal connections required to facilitate the vertical alignment of the RC planks and flanges shall be provided.

7.10.12 *Opening and Voids in the In-situ Concrete Topping Slab*

The effects of openings and voids in the in-situ concrete topping slab shall be considered in the diaphragm design. Detailing around the openings and voids must be done in accordance with Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS.

7.10.13 *Collectors*

7.10.13.1 Collectors shall extend from the vertical elements of the lateral-force-resisting system across all or part of the diaphragm depth as required to transfer shear from the diaphragm to the vertical element (as shown in Fig. 17). It shall be permitted to discontinue a collector along lengths of vertical elements of the lateral-force-resisting system where transfer of design collector forces is not required.

7.10.13.2 Collectors shall be designed as tension members, compression members, or both, in accordance with the criteria for axial member in Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS.

7.10.13.3 Where a collector is designed to transfer forces to a vertical element, collector reinforcement shall extend along the vertical element to at least the greater of (a) and (b):

a) The length required to develop the reinforcement in tension; and

b) The length required to transmit the design forces to the vertical element through shear-friction in accordance with 7.12, through mechanical connectors, or through other force transfer mechanisms.

COLLECTOR ELEMENT TO TRANSFER FORCE
BETWEEN DIAPHRAGM AND SHEAR WALL

FIG. 17 COLLECTORS BETWEEN FRAMING ELEMENTS

7.10.14 *Reinforcement Limits*

7.10.14.1 Reinforcement to resist shrinkage and temperature stresses shall be estimated according to relevant clauses of Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS.

7.10.14.2 Reinforcement designed to resist diaphragm in-plane forces shall be in addition to reinforcement designed to resist other load effects, except that reinforcement designed to resist shrinkage and temperature effects shall be permitted to also resist the diaphragm in-plane forces.

7.10.15 *Reinforcement Detailing*

7.10.15.1 Concrete cover for reinforcement shall be in accordance with good practice [C-7(2)].

7.10.15.2 Development lengths of deformed and prestressed reinforcement shall be in accordance with good practice [C-7(2)] and [C-7(3)], respectively, unless longer lengths are required by high seismic zone requirements.

7.10.15.3 Splices of deformed reinforcement shall be in accordance with Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS.

7.10.15.4 Bundled bars shall be in accordance with Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS.

7.10.16 *Reinforcement Spacing*

7.10.16.1 Minimum spacing of reinforcement shall be in accordance with Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS.

7.10.16.2 Maximum spacing of deformed reinforcement shall be the lesser of five times the diaphragm thickness and 450 mm.

7.10.17 *Diaphragm and Collector Reinforcement*

7.10.17.1 Tensile or compressive force in reinforcement at each section of the diaphragm or collector shall be developed on each side of that section.

7.10.17.2 Reinforcement provided to resist tension shall extend beyond the point at which it is no longer required to resist tension for at least a length of L_d, except at diaphragm edges and at expansion joints.

7.10.17.3 Welded wire mesh of diameter 6 mm or higher shall be used in the structural topping concrete to achieve the diaphragm reinforcement.

7.10.18 *Other Parameters*

7.10.18.1 Heavy duty PVC or metal conduits with diameter up to 20 mm are preferable. Larger diameter conduits (25 mm or 32 mm or higher) may be permitted as per project requirements with proportionately higher thickness of structural topping.

7.10.18.2 Single junction box shall be used to conduct the conduits.

7.11 Designing of Bearing Region

7.11.1 *General*

The bearing region shall ensure structural integrity through the following measures:

a) Overlapping reinforcement in reinforced bearing zones;

b) Physical restraint to prevent loss of bearing due to movement; and

c) Tolerance provisions to accommodate cumulative deviations due to production and erection.

7.11.2 *Net Bearing Width of Non-Isolated Members*

The net bearing width of a member shall not be less than 40 mm and shall be determined by:

$$\text{Net bearing width} = \frac{\text{ultimate support reaction}}{\text{effective bearing length} \times \text{ultimate bearing stress}}$$

The net bearing width should be increased to cater for any free movement permitted or rotation of the bearing about the support.

7.11.3 *Effective Bearing Length*

The effective bearing length of a member shall be taken as the least of:

a) Actual bearing length;

b) One-half of bearing length plus 100 mm; or

c) 600 mm.

7.11.4 *Design Ultimate Bearing Stress*

The design ultimate bearing stress shall be based on the weaker bearing surface and shall be:

a) $0.4f_{ck}$ for dry concrete bearings;

b) $0.6f_{ck}$ for mortar-bedded concrete bearings; or

c) $0.8f_{ck}$ for steel bearing plates embedded in concrete, provided the plate dimensions do not exceed 40 percent of the supporting concrete dimension.

An intermediate value of bearing stress between dry and bedded bearings may be used for flexible bedding.

7.11.5 *Net Bearing Width of Isolated Members*

For isolated members, the net bearing width shall be increased by 20 mm over that required for non-isolated members.

7.11.6 *Minimum Dimensions of Bearing*

The minimum requirement for bearing length shall be as per Fig. 18.

19A) PLAN VIEW

19B) SECTION A-A

FIG. 19 SCHEMATIC ARRANGEMENT OF ALLOWANCES FOR BEARING

7.11.8 *Allowances for Spalling at Supports*

The design shall account for reduction in effective bearing area due to potential spalling, in accordance with Table 3 and Table 4. When determining the outer edge of a support or the end of a supported member, chamfers occurring within the areas subjected to spalling may be excluded.

Table 3 Allowances for Effects of Spalling at Supports

(*Clause* 7.11.8)

Sl No. (1)	**Material of Support** (2)	**Ineffective Distance, Measured from Outer Edge of Support** mm (3)
i)	Steel	0
ii)	Concrete ≥ M30	15
iii)	Concrete < M30	25
iv)	RC with outer edge less than 300 mm deep and vertical loop bar not greater than 12 mm	Nominal cover to reinforcement on outer face of support
v)	RC with outer edge less than 300 mm deep and vertical loop bar is 16 mm or above	Nominal cover plus inner radius of bend of bars

Table 4 Allowances for Effects of Spalling at Supported Members

(*Clause* 7.11.8)

Sl No. (1)	**Reinforcement at Bearing of Support Member** (2)	**Ineffective Distance, Measured from Outer Edge of Support** mm (3)
i)	Straight bar, horizontal loops or vertical loops of 12 mm diameter or less	Greater of nominal cover or 10 mm
ii)	Tendons or straight bars exposed at end of member	0
iii)	Vertical loops of 16 mm diameter or above	Nominal end cover plus inner radius of bend of bars

7.11.9 *Shims*

Plastic or metal shims shall be used as per structural and durability requirements and shall be specified as per design requirements.

7.11.9.1 Steel shims shall not be used at areas susceptible to spalling. Load transfer through shims shall be included in the structural design.

7.11.9.2 The total thickness of individual shims shall not exceed 40 mm.

7.11.9.3 For joint gaps exceeding 40 mm, steel shims shall be used and shall be tack welded when shim thickness exceeds 40 mm to ensure load transfer and stability. Minimum thickness of shim plates shall be 5 mm.

7.11.10 *Allowance for Construction Inaccuracies*

The design shall include allowances for construction inaccuracies due to deviations in layout, manufacturing and erection. In absence of statistical deviation data, the minimum allowances shall be:

a) 15 mm or 3 mm/m for steel or precast concrete supports;

b) 20 mm or 4 mm/m for masonry supports; and

c) 25 mm or 5 mm/m for in-situ concrete supports.

7.11.11 *Bearings Transmitting Compressive Forces*

The horizontal joints between load-bearing walls or columns shall be designed to resist all the forces and moments implicit in the assumptions made in analysing the structure as a whole and in designing the individual member to be joined. In the absence of more accurate information derived from a comprehensive programme of suitable tests, the area of concrete to be considered in calculating the strength of the joint in a wall or column shall be as per 8.3.2. Joints and joint reinforcement shall be detailed to prevent premature splitting or spalling at member ends.

7.11.12 *Other Forces at Bearings*

a) *Horizontal forces at bearing* — The horizontal forces at bearings may be induced by creep, shrinkage, temperature effects, misalignment, lack of plumb or other causes. When these forces are significant, the structural capacity of the supporting member may be impaired. A minimal force of 0.2 V_u (vertical or shear force on the bearing) shall be used in design. Allowances should be made by the provision of:

   1) Sliding bearings which allow longitudinal and lateral movement;

   2) Additional lateral reinforcement at the top of the supporting member; or

   3) Continuity reinforcement which ties the ends of the supported members together.

b) *Rotation at bearing* — Suitable bearings should be used to accommodate the rotations at end supports in particular for flexural members. Allowances should be made for any consequential increases in bending moments or bearing stresses due to rotations.

7.11.13 *Design of Bearing on Plain Concrete*

7.11.13.1 Plain concrete bearing (*see* Fig. 20) shall be used in situations where the bearing is uniform and the bearing stresses are low.

7.11.13.2 In other situations, and in thin-stemmed components where the bearing area is less than 12 500 mm^2, a minimum reinforcement equal to $N_u/0.65f_y$ (but not less than one bar of 10 mm diameter) is recommended. If horizontal load is not present, a minimum recommended value of $N_u = 0.2\ V_u$ shall be used.

where

N_u = factored axial force (minimum shall be 0.2 V_u); and

V_u = factored shear force.

7.11.13.3 The design bearing strength of plain concrete shall be calculated based on the following equation as given below:

Supporting area is wider in all sides than the loaded area (lesser of)

$$V_{uR} = (0.45 f_{ck} A_1)\sqrt{\frac{A_2}{A_1}}$$

$\sqrt{\frac{A_2}{A_1}}$ shall not exceed 2,

$$V_{uR} = 2(0.45 f_{ck} A_1)$$

Other cases

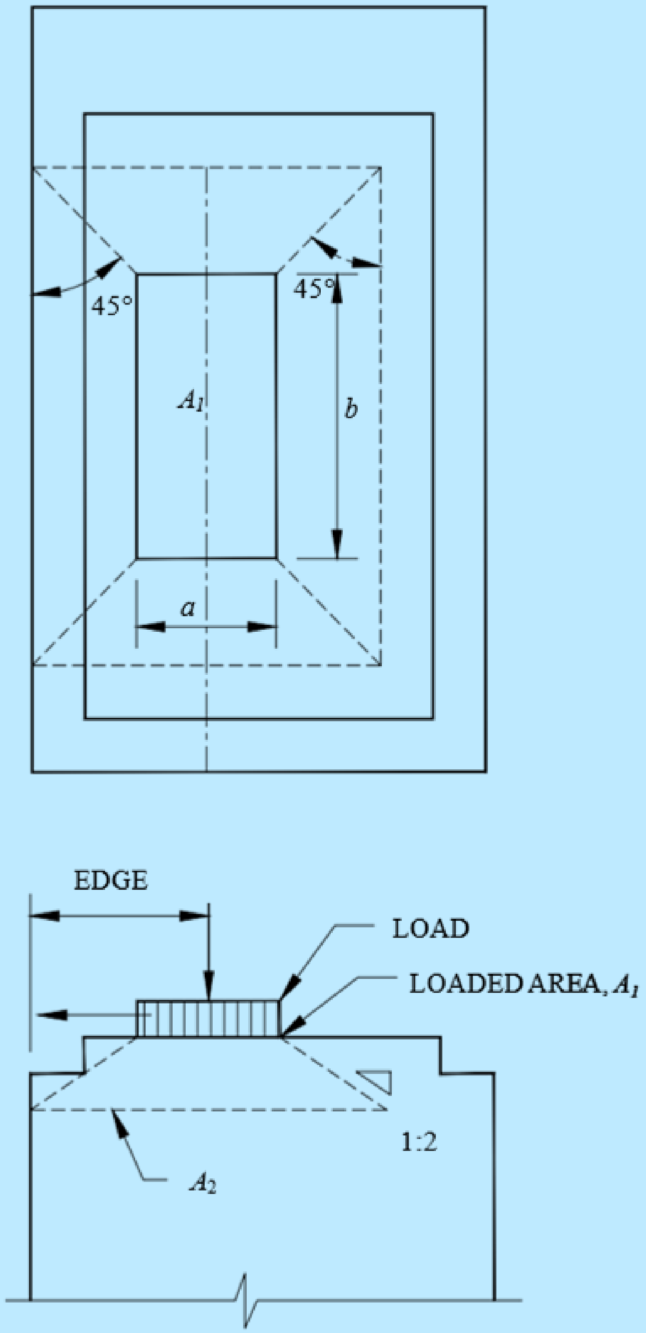
$$V_{uR} = 0.45 f_{ck} A_1$$

where

V_{uR} = design shear resistance;

A_1 = loaded area (bearing constant area) (*see* Fig. 20); and

A_2 = area of the lower base of pyramid, cone or tapered wedge (*see* Fig. 20).



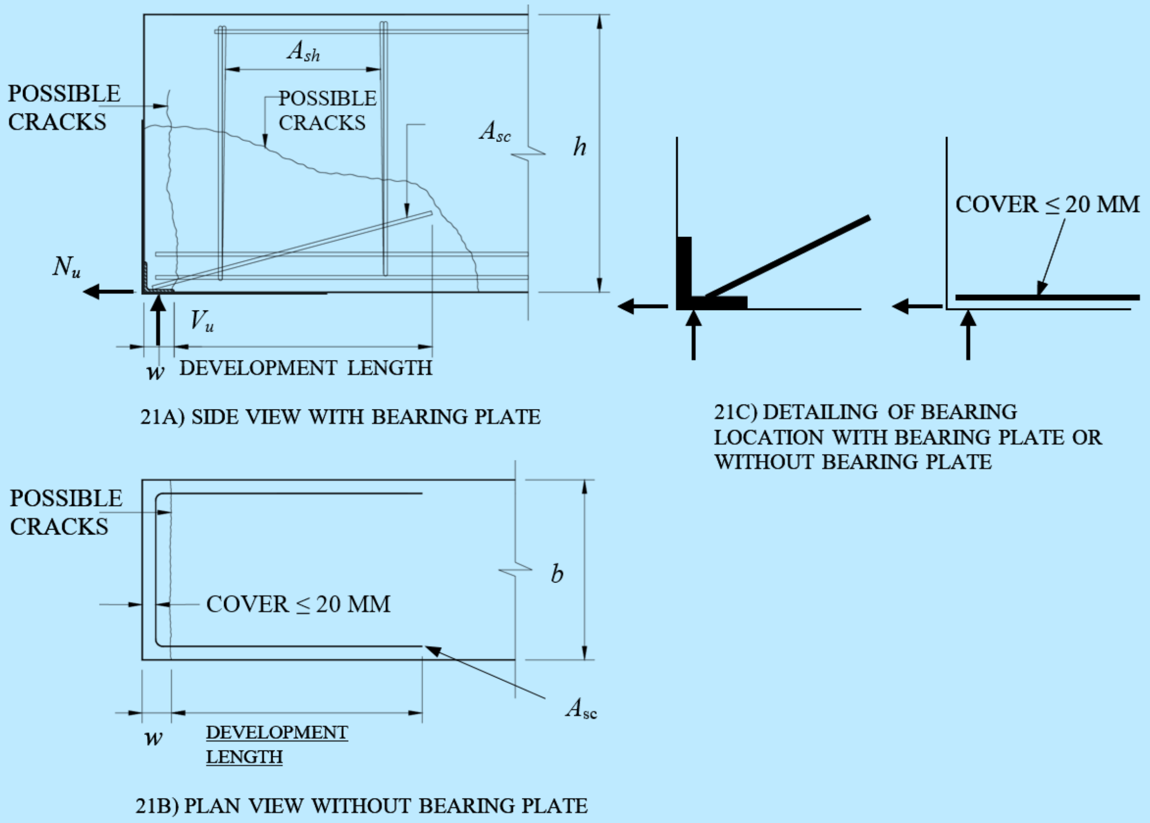
A_1 = LOADED AREA (BEARING CONTACT AREA)
A_2 = AREA OF THE LOWER BASE OF PYRAMID, CONE OR TAPERED WEDGE

FIG. 20 BEARING ON PLAIN CONCRETE

7.11.14 *Design of Reinforced Concrete Bearing* (*for thin Stem Elements and Rectangular Beams*)

7.11.14.1 If the applied load V_u, exceeds the design bearing strength V_{uR}, as calculated by equation in 7.11.13.3, reinforcement shall be provided in the bearing area as per Fig. 21.

7.11.14.2 The area of reinforcement $A_{vf} + A_n$ shall be calculated as per 7.12 and 7.11.16. This reinforcement shall be appropriately developed on each side of the vertical crack by development length, hooks, or welding to an anchor bar, bearing plate, or angle.



21A) SIDE VIEW WITH BEARING PLATE

21C) DETAILING OF BEARING LOCATION WITH BEARING PLATE OR WITHOUT BEARING PLATE

21B) PLAN VIEW WITHOUT BEARING PLATE

FIG. 21 REINFORCED CONCRETE BEARING

7.11.14.3 The area of vertical shear reinforcement shall be calculated as follows:

$$A_{sh} = \frac{(A_{vf} + A_n)f_y}{\mu f_{ys}}$$

where

A_{vf} = area of shear friction reinforcement;

A_n = area of tension reinforcement;

f_y = yield strength of tension reinforcement;

μ = coefficient of friction as per Table 6; and

f_{ys} = yield strength of shear reinforcement.

7.11.14.4 Diagonal tension reinforcement such as stirrups or welded-wire mesh may be counted as A_{sh} but shall not be added to separately designed shear reinforcement.

7.11.14.5 When components are subjected to bearing force more than $0.45f_{ck}A_1$ confinement reinforcement in all directions shall be provided. A_1 shall be considered as per Fig. 20.

7.11.15 *Dapped End Bearing* (*Thin Stem and Regular Beams*)

7.11.15.1 Dapped end members shall be designed for the potential failure modes shown in Fig. 22 to Fig. 24 with the reinforcement required for each consideration.

7.11.15.2 Dap reinforcement shall be provided in all cases where one or more of the following conditions:

a) The depth of the recess exceeds the lesser of 0.2 H or 200 mm;

b) The length of the recess (L_p in Fig. 22) exceeds 300 mm for non-thin-stemmed components and the nib (the concrete section above the dap) is not designed for the full flexural and shear capacity; and

c) For non-thin-stemmed components, less than 1/3 of the main flexural reinforcement extends to the end of the component above the dap.

7.11.15.3 Thin-stemmed components such as double tees, T beam, etc, shall be designed with the following additional consideration:

a) Stem width is 125 mm or less;

b) Vertical hanger reinforcement or inclined reinforcement at an angle greater than 90° measured from horizontal; and

c) Dap height ≤ 0.5 h.

7.11.15.4 The design equations given in this section shall be considered for cases where shear span-to-depth ratio (a_v/d) do not exceed 1.0.

24B) INCLINED L-SHAPED REBAR

24C) WELDED WIRE REBAR

FIG. 24 CONFIGURATION OF DAP REINFORCEMENT FOR THIN-STEMMED DAPPED ENDS

7.11.15.7 The area of horizontal reinforcement A_s (area of reinforcement for flexure and axial tension in the extended end) shall be the larger of the two values calculated using the equations given below. The values of A_f, A_n shall be calculated as per 7.11.17 and A_{vf} is as defined under 7.12:

$$A_s = A_f + A_n \text{ , or}$$

$$A_s = \frac{2}{3} A_{vf} + A_n$$

7.11.15.8 The area of horizontal reinforcement A_h (area of direct shear reinforcement) shall be provided in the nib to arrest Crack 2 as per the following and shall be distributed within 2/3 d measured from the primary tension reinforcement A_s:

$$A_h = 0.5(A_s - A_n)$$

7.11.15.9 The area of hanger reinforcement A_{sh} shall be provided to arrest Crack 3, shall be as per the following:

$$A_{sh} = \frac{V_u}{0.75 f_y}$$

7.11.15.10 The area of vertical shear reinforcement A_v shall be provided to arrest Crack 4 as per the following:

$$V_{uR} = 0.75(A_v f_y + A_h f_y + 0.15\sqrt{f_{ck}} bd)$$

$$\text{Minimum } A_v = \frac{1}{2f_y}(1.34V_u - 0.15\sqrt{f_{ck}} bd)$$

7.11.15.11 The anchorage of reinforcement shall be as per the following:

a) Horizontal bars A_s shall be extended a minimum of L_d beyond Crack 5 and anchored at the end of the component by welding to cross bars, plates, or angles;

b) Horizontal bars A_h shall be extended a minimum of L_d, beyond Crack 2 and anchored at the end of the component by hooks or other suitable means;

c) To ensure development of hanger reinforcement A_{sh}, the rebar shall be bent and continued parallel to the bottom of the component, or a separate horizontal anchored reinforcement with $A'_{sh} \geq A_{sh}$ shall be provided. The extension of reinforcement (A'_{sh}) at bottom of the component must be at least L_d beyond Crack 5. The A'_{sh}, reinforcement may be anchored on the dap side by welding it to a plate, angle, or cross bar;

d) The beam flexure reinforcement may also be used to ensure development of A_{sh} reinforcement, provided that the flexural reinforcement is adequately anchored on the dap side and the A_{sh} reinforcement is wrapped around the flexural reinforcement;

e) In thin-stemmed components, it is recommended that the extension of the hanger reinforcement be greater than L_d. A'_{sh} shall extend a distance that is the greater of 1.5 L_d of the strand past the face of the dap or 2.0 L_d of A'_{sh} beyond the diagonal Crack 5;

f) Vertical reinforcement A_v should be properly anchored by hooks, as required by Part C/Section 5 of this NBCS;

g) Thin-stemmed components, except for the vertical 'Z' configuration, which has the bar welded to the plate, should have at least one 12 mm diameter rebar welded to the bearing plate or have equivalent development length (L-rebar); and

h) Welded-wire reinforcement in place of bars may be used for reinforcement. It should be anchored in accordance with Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS. In thin-stemmed components the use of welded-wire reinforcement should be limited to situations where it is placed symmetrically in the width of the stem.

7.11.15.12 *Other considerations*

In addition to the reinforcement for the dapped end, it is important that the following be considered:

a) The depth of the extended end should not be less than about one half the depth of the beam, unless the beam is deeper than necessary for other than structural reasons;

b) The hanger reinforcement A_{sh} should be placed as close as practical to the re-entrant corner and as symmetrically as possible around the centroid of the section being considered. This reinforcement requirement is not additive to other shear-reinforcement requirements but should be in addition to torsion reinforcement;

c) The shear strength of the full-depth beam behind the dap must be verified;

d) For thin-stemmed components, for a distance of $2H$ beyond the dap the concrete contribution to shear strength should be limited to:

$$V_c = 0.15\sqrt{f_{ck}}b_w d_p$$

or

$$V_c = 0.23\sqrt{f_{ck}}b_w d_p, \text{ where at least two bonded strands in the extended end are present}$$

where

b_w = average width of the stem for the full depth of the section; and

d_p = distance from the top to the centroid of the prestressing strand for the full depth section and shall not be less than 0.8 H.

e) For thin-stemmed components, for a distance 2 H beyond the dap, the reinforcement contribution to shear strength V_s shall be limited as per the following:

$$V_s = 0.15\sqrt{f_{ck}}\, b_w d_p$$

7.11.16 *Ledges*

7.11.16.1 *General*

Beam and wall ledges (as shown in Fig. 25) shall be designed as per the following guidelines. Hanger steel requirements for the ledge in a wall need not be satisfied except where penetrations occur just below ledges. The design procedure explained in this section shall be applicable for the following cases:

a) $N_u \leq V_u$;

b) Ledges with heights of 200 mm to 450 mm;

c) Ledge projections of 150 mm to 250 mm;

d) Bearing widths of components on the ledge ranging from 100 mm to 300 mm;

e) Distances of end load to end of ledge ranging from 100 mm to 900 mm; and

f) Design concrete compressive strengths f_{ck} of 30 MPa to 80 MPa.

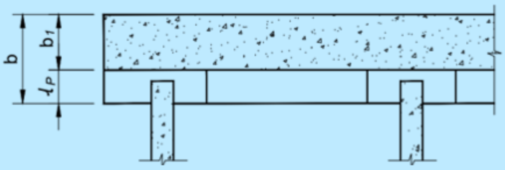
SECTION B-B

EQUILIBRIUM AND CONNECTION REINFORCEMENT OF LEDGER BEAM

(NOTE: REINFORCEMENT REQUIRED FOR FLEXURE AND INTERNAL TENSIONS NOT SHOWN)



ASYMMETRIC SYMMETRIC

SECTION A-A

FIG. 25 DESIGN OF BEAM LEDGES

7.11.16.2 For shear strength of ledge for concentrated loads, not near the ends, where $d_e \geq 0.5\ b_t + h_l + l_p$, a symmetric failure controls the design punching shear strength of the ledge shall be determined as the lesser of following two equations:

$$V_{uR} = 0.056\gamma\beta\sqrt{f_{ck}}h_l(b_t + 2h_l + 2l_p)$$

or

$$V_{uR} = 0.028\gamma\beta\sqrt{f_{ck}}h_l(b_t + 2h_l + s + 2l_p)$$

For concentrated loads that are near ends, where $d_e \leq 0.5\ b_t + h_l + l_p$, an asymmetric failure controls the design punching shear strength of the ledge and shall be as per the following:

$$V_{uR} = 0.056\gamma\beta\sqrt{f_{ck}}h_l(0.5b_t + h_l + d_e + l_p)$$

or

$$V_{uR} = 0.56\gamma\beta\sqrt{f_{ck}}h_l(0.5b_t + h_l + d_e + l_p)$$

where

γ = $\sqrt{1 + 12.5\frac{f_{pc}}{f_{ck}}}$, a factor for the effect of prestressing, 1 for precast beams;

β = coefficient of shear strength based on R (as per Fig. 26);

h_l = height of beam ledge;

b_t = bearing width;

l_p = length of ledge projection;

s = minimum spacing of concentrated loads;

d_e = distance from centre of load to the end of the ledge; and

f_{pc} = average prestress force after losses divided by gross concrete area of beam.

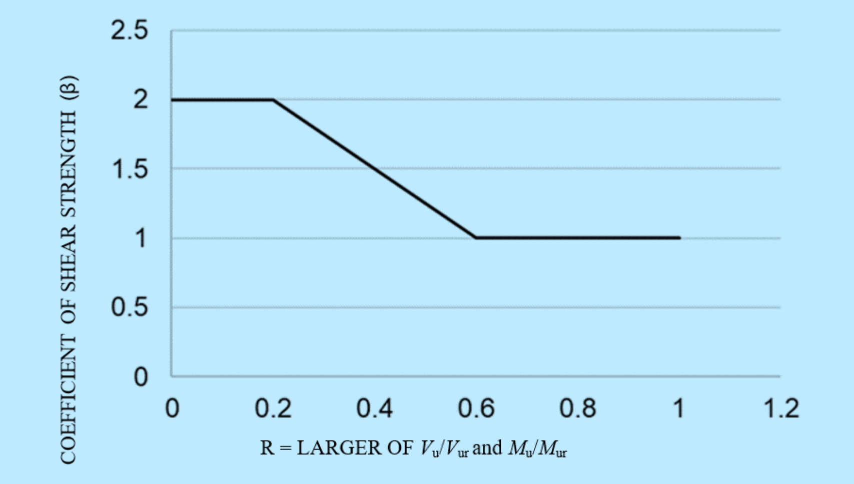


FIG. 26 COEFFICIENT OF SHEAR STRENGTH

7.11.16.4 For ledges supporting a continuous load or a series of closely spaced concentrated loads, punching shear strength per metre run shall be determined as per the following:

$$V_{uR} = 0.675\sqrt{f_{ck}}h_l$$

7.11.16.5 If the applied factored load exceeds the strength as determined above, the ledge shall be designed for shear transfer and diagonal tension in accordance with **7.11.15.8** through **7.11.15.10**.

7.11.16.6 Transverse (cantilever) bending of the ledge requires flexural reinforcement ($A_s = A_f + A_n$), shall be computed using **7.11.17.5**. Such reinforcement shall be uniformly spaced over a width of 6h_l on either side of the bearing, but not to exceed half the distance to the next load. Bar spacing shall not exceed the ledge depth h_l or 450 mm whichever is less.

7.11.16.7 Longitudinal reinforcements shall be placed in both the top and bottom of the ledge portion of the beam and calculated as per the following:

$$A_l = \frac{200 l_p d_l}{0.75 f_y}$$

where

d_l = design depth of A_l reinforcement in Fig. 25.

7.11.16.8 Hanger steel A_{sh} shall be computed using following equation and distributed in the web of the beam. The reinforcement shall be uniformly spaced over a width of 6 h_l on either side of the bearing, but shall not exceed half the distance to the next load. The area of reinforcement shall not be additive to shear and torsional reinforcement.

$$A_{sh} = \frac{Vu}{0.75 f_y}(m)$$

where

m for L beam

$$m = \frac{(d_s + a) - \left(3 - 2\frac{h_l}{h}\right)\left(\frac{h_l}{h}\right)^2 \left(\frac{b_l}{2}\right) - e\gamma_t \frac{x_l^2 y_l}{(x_l^2 y_l + x_w^2 y_w)}}{d_s} \geq 0.6, and$$

m for inverted tee-beam

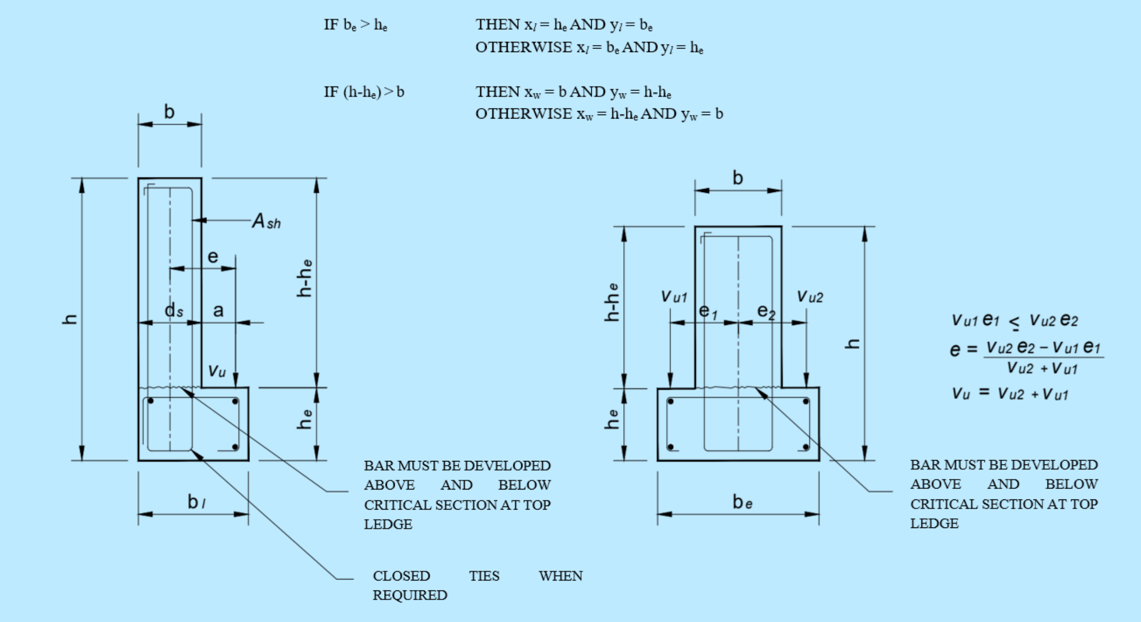
$$m = \frac{\left(\frac{b}{2} + e\right) - \left(3 - 2\frac{h_l}{h}\right)\left(\frac{h_l}{h}\right)^2 \left(\frac{b}{2}\right) - e\gamma_t \frac{x_l^2 y_l}{(x_l^2 y_l + x_w^2 y_w)}}{d_s} \geq 0.4$$

where

d_S = distance from outside face of web to A_{SH} reinforcement;

b_l = width of web plus ledge being designed;

x_l, y_l, x_W, y_W, = defined in Fig. 27.



IF b_e > h_e
THEN x_l = h_e AND y_l = b_e
OTHERWISE x_l = b_e AND y_l = h_e

FIG. 27 LEDGE HANGER STEEL GEOMETRY

7.11.17 *Concrete Corbels*

7.11.17.1 *General*

Concrete corbels are short cantilevers that support other components and transmit the load to the supporting component and tend to act as simple trusses or deep beams (*see* Fig. 28).

7.11.17.2 The design based on strut and-tie method shall be as per Part C/Section 5 of this NBCS. For steel brackets, Part C/Section 6A of this NBCS shall be referred.

7.11.17.3 The cantilever beam method of designing a corbel presented in this section shall be used according to following limitations:

a) $a_V/d \leq 1$; and

b) $N_U \leq V_U$.

7.11.17.4 The dimensions of a corbel shall be selected such that the nominal shear strength shall not exceed the strength calculated as per Table 6.

7.11.17.5 The area of primary tension reinforcement A_{sc} shall be greater of ($A_f + A_n$) and (2/3) $A_{vf} + A_n$

7.11.17.6 The area of reinforcement A_f shall be calculated as per the following equation:

$$A_f = \frac{V_u a_v + N_u(h-d)}{0.7 f_y d}$$

7.11.17.7 The area of reinforcement A_n shall be calculated as per the following equation:

$$A_n = \frac{N_u}{0.75 f_y}$$

7.11.17.8 The area of reinforcement A_{vf} shall be calculated as per shear friction (*see* 7.12).

7.11.17.9 Unless tensile forces are prevented from being applied to the bracket or corbel, N_u shall be considered as $0.2V_u$ or as specified in the project.

1 THE MAIN REBAR FOR A_{SC} SHOULD BE EXTENDED BEYOND THE CRITICAL SECTION AND DEVELOPED INTO THE SUPPORTING MEMBER.

2 WELDED BAR OR ALTERNATE DETAILING SHALL BE FOLLOWED FOR THE OUTSIDE FREE EDGE.

3 HORIZONTAL CLOSED TIES SHALL BE USED FOR A_H

FIG. 28 DESIGN OF CONCRETE CORBELS

7.11.17.10 If bearing pads are used to avoid tensile forces, the value of N_u that corresponds to the force causing the pad to slip shall be considered.

7.11.17.11 Minimum reinforcement (A_{sc}) shall be calculated as per the following equation. Where the corbel depth is larger than required by design a reduced depth *d* may be used consistently in all the design equations:

$$A_{sc,min} = 0.032\frac{f_{ck}}{f_y}bd$$

7.11.17.12 The area of stirrups (A_h) shall be calculated as per the following equation:

$$A_h \geq 0.5(A_{sc} - A_n)$$

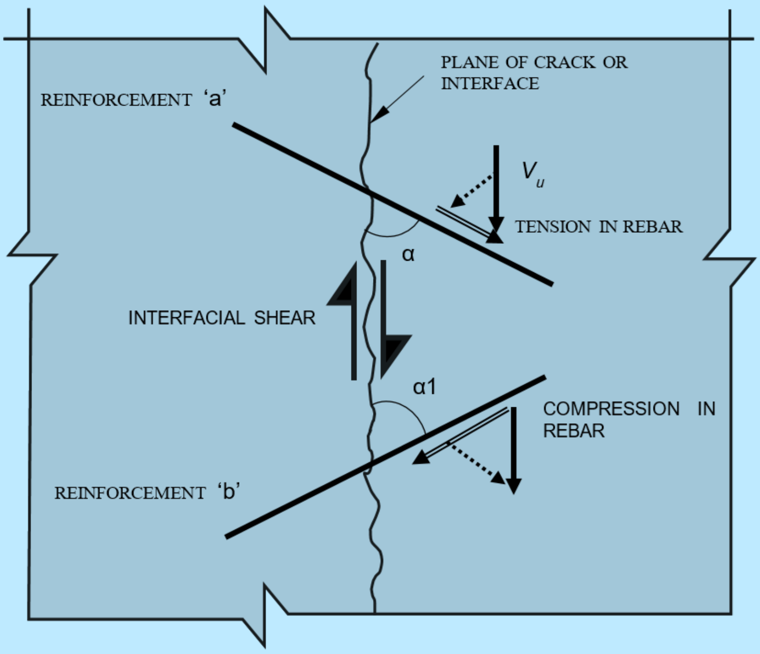
7.11.17.13 The shear reinforcement shall be provided as closed stirrups and uniformly distributed within 2/3 d measured from the primary tension reinforcement.

7.11.17.14 The development length for primary tension reinforcing bar shall be as per good practice [C-7(2)]. Development length for tension reinforcement shall be measured from the assumed failure plane (face of the supporting member). For member not having enough embedment length, hooked bars shall be used.

7.11.17.15 The main tension steel within the concrete corbel shall be developed at the outer edge of the corbel by welding to a cross bar, bearing plate with cross bar, angle section or bending along the depth of corbel.

7.12 Shear Friction

Shear friction shall be applied to consider shear transfer across interface between dissimilar materials or interface between concrete cast at different time or across a shear plane as shown in Fig. 29, reinforcement ‘a’. The following clauses shall be used.



NOTE – Reinforcement ‘a’ shall be considered in shear transfer and reinforcement ‘b’ shall be neglected.

FIG. 29 SHEAR FRICTION REINFORCEMENT

7.12.1 *Nominal Shear Strength*

7.12.1.1 Value of V_{uR} across the assumed shear plane shall be calculated using equation in 7.12.1.2 or 7.12.1.3 depending on the angle of shear reinforcement.

7.12.1.2 If shear-friction reinforcement is perpendicular to the shear plane, nominal shear strength across the assumed shear plane shall be calculated by:

$$V_{uR} = 0.75\mu A_{vf} f_y$$

7.12.1.3 If shear-friction reinforcement is inclined to the shear plane and the shear force induces tension in the shear friction reinforcement, nominal shear strength across the assumed shear plane shall be calculated by:

$$V_{uR} = 0.75\ A_{vf} f_y\ (\mu\ sin\ sin\ \alpha + cos\ cos\ \alpha)$$

where

A_{vf} = area of reinforcement crossing the assumed shear plane to resist shear;

μ = coefficient of friction in accordance with Table 6; and

α = angle between shear-friction reinforcement and assumed shear plane.

7.12.2 The value of V_{uR} across the assumed shear plane shall not exceed the limits in Table 5. Where concretes of different strengths are cast against each other, the lesser value of f_{ck} shall be used in Table 5.

Table 5 Maximum V_{uR} Across the Assumed Shear Plane

(*Clause* 7.12.2)

Sl No.	**Surface Condition**	**Maximum** V_{uR}	
(1)	(2)	(3)	
i)	Concrete placed monolithically or placed against intentionally roughened surface (amplitude of 6 mm or more)	$0.12 f_{ck} A_{cr}$, *or* $(2.475 + 0.049 f_{ck})\ A_{cr}$, *or* $8.25 A_{cr}$	Equation given in **7.12.1.2** least of the three
ii)	Other cases	$0.12 f_{ck} A_{cr}$ or $4.125 A_{cr}$	Equation given in **7.12.1.3** least of the two

Table 6 Coefficient of Friction

(*Clauses* 7.11.14.3, 7.11.17.4 *and* 7.12.1.3)

Sl No.	**Contact Surface Condition**	**Coefficient of Friction**
(1)	(2)	(3)
i)	Concrete placed monolithically	1.4
ii)	Concrete placed against hardened concrete that is clean, free of laitance and intentionally roughened to a full amplitude of approximately 6 mm	1.0
iii)	Concrete placed against hardened concrete that is clean, free of laitance and not intentionally roughened	0.6
iv)	Concrete placed against as-rolled structural steel that is clean, free of paint and with shear transferred across the contact surface by headed studs or by welded deformed bars or wire	0.7

7.12.3 The frictional component of compression load (if any) present at the interface shall be considered along with the shear friction capacity.

7.12.4 Shear friction capacity shall not be considered for a joint producing compression in the joint reinforcement as shown in Fig. 29 reinforcement 'b'.

7.13 Serviceability Design Checks

7.13.1 *Deflection*

Deflection calculations and permissible limits shall comply with the provisions of Part C/Section 5 of this NBCS. Partial fixity provided by the structural topping and nominal connections may be considered for serviceability checks.

7.13.2 *Crack*

The relevant provisions of good practice [C-7(2)] shall be followed for crack width calculations and limits. If structural cracks are observed on the tension face of the element, testing of the element shall be carried out in accordance with **10** or as directed by engineer-in-charge and the client.

7.13.3 *In-Service Considerations*

The relevant provisions of good practice [C-7(2)] shall be followed for service consideration calculations and limits.

7.14 Design of Demoulding, Handling Systems and Temporary Forces

7.14.1 *Demoulding Forces*

Forces on the elements during lifting from the casting bed due to suction or adhesion between the precast elements and the mould should be accounted while deciding the strength of concrete. These are accounted for by applying an equivalent load factor to the self-weight of the member and treating it as an equivalent static force to evaluate the stresses in the precast element. Table 7 gives recommended minimum values of equivalent load factor for demoulding forces for different product types and finishes.

Table 7 Recommended Load Factors to Account for Forces in Demoulding of Elements

(*Clauses* 7.14.1, 10.8 *and* 10.8.3)

Sl No.	Product Type	Finish	
		Exposed Aggregate with Retarder	Smooth Mould (form oil only)
(1)	(2)	(3)	(4)
i)	Flat with removable side forms. No formed rebates or reveals	1.2	1.3
ii)	Flat with removable side forms with formed rebates or reveals	1.3	1.4
iii)	Fluted with proper draft	1.4	1.6
iv)	Sculptured	1.5	1.7

NOTES

1 These factors are to be applied to the flexural design of precast elements only. For lifting inserts, *see* Table 10.

2 The above values are recommended values only. Guidance should also be sought from the precast manufacturer based on their pre-casting experience if the load factors need to be increased.

3 The associated imposed loads or wind loads, if any, are to be assessed and considered under the appropriate load combination.

7.14.2 *Handling Stresses*

Precast elements shall be designed and handled to prevent permanent damage during demoulding, storage, transportation, and erection. Design shall account for all loads acting during these stages. Minor cracks within acceptable design crack widths shall be repaired using methods approved by the contract or chemical supplier guidelines.

7.14.3 *Handling and Transportation*

An allowance should be made for dynamic loads and impact forces arising in handling, transportation and erection. Similar to demoulding force consideration, Table 8 gives recommended values for equivalent load factor to be applied to the self-weight of members to allow for these forces.

Table 8 Recommended Load Factors to Account for Dynamic Forces Arising During Handling, Transportation and Erection of Elements

(*Clause* 7.14.3)

Sl No. (1)	Stage (2)	Load Factor (3)
i)	Yard handling	1.2
ii)	Transportation	1.5
iii)	Erection	1.2

NOTES

1 These factors are to be applied to the flexural design of precast elements only. For lifting inserts, refer **7.14.6**.

2 The above values are recommended values only. Under certain conditions higher factors may apply that is certain unfavourable load conditions.

3 The associated imposed loads or wind loads, if any, are to be assessed and considered with the appropriate load combination.

7.14.4 *Early Demoulding/Handling of Precast Element*

For precast elements lifted and handled prior to gaining full strength the elements together with any lifting inserts should be designed accordingly. Recommended minimum concrete strengths for lifting and handling of precast elements are given in Table 9. Precast elements should be designed, using these lower strengths, to span between lifting points without excessive cracking or deflection. For prestressed concrete, consideration should also be given to stresses resulting from transfer of prestressing forces.

Table 9 Recommended Minimum Concrete Strength for Lifting and Handling

(*Clauses* 7.14.4 *and* 10.8.4.1)

Sl No. (1)	Application (2)	Minimum Concrete Strength N/mm^2 (3)
i)	None specified, fine controlled crane, non-prestressed	10*
ii)	Lifting which involves significant impact or high acceleration	15*
iii)	All units where concrete strength for lifting is specified in the specification	As specified
iv)	Concentrically prestressed elements (piles, wall panels, or thin floor slabs)	20
v)	Eccentrically prestressed (T beam, deep flowing units)	25
vi)	Highly stressed prestressed elements	30 or as specified

---

*Depending on anchor length or as recommended by insert manufacturer.

7.14.5 *Temporary Stages/Erection Sequence*

The design of precast elements at temporary stages can be critical compared to the permanent stages. Consideration should be given to the loading imposed on the precast elements during each phase of construction. The following shall be verified:

a) Precast sections of composite elements which are required to support self-weight plus construction load prior to casting of an in-situ topping;

b) Lower precast floor slabs or precast stair flights which support propping to upper levels during installation; and

c) Bearing or halving joints which support higher temporary construction loads because of back propping to upper levels.

The design should also take into consideration that the structural action and framing might be different during the temporary stages resulting in higher stresses in individual members.

7.14.6 *Lifting Inserts*

The number of lifting inserts and location of inserts shall be decided by the following:

a) Lifting insert capacity (safe working load);

b) Total weight of the element;

c) Strength of concrete at age of lifting;

d) Shape of the unit;

e) Location of the inserts so that the failure of any one insert does not cause failure of the entire lifting system thereby ensuring the element can still be safely supported;

f) Position of any cut-outs and/or openings;

g) Rigging arrangement; and

h) Anchorage of inserts.

All lifting inserts shall be designed by accounting the factors of safety given in Table 10. Typically lifting inserts shall be designed with a factor of safety of 4.

Table 10 Recommended Factors of Safety for Lifting Inserts

(*Table 7 and Clause 7.14.6*)

Sl No. (1)	Item (2)	Recommended Factor of Safety (3)
i)	Bracing members	2
ii)	Bracing connections	3
iii)	Bracing inserts cast into precast members	3
iv)	Lifting inserts, normal circumstances	4
v)	Lifting inserts, multiple usage	5
vi)	Rebar inserts, single usage	2
vii)	Rebar inserts, multiple usage	4

7.14.7 *Bracing Design*

Bracing should be designed for both construction and wind loading. The construction load should be a minimum value of 1.5 kN/m² but should be increased if considered appropriate.

Wind loads shall be calculated in accordance Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS and the bracing shall be designed for it.

8 JOINTS AND CONNECTIONS

8.1 Basic Design Considerations

A joint shall be considered based on the action of force transfer (tension, compression, shear, moment, etc) at an interface (one or many) between the precast components. A connection, which is a zone that includes various joints, shall be designed in combination of any of the following forces:

a) Compressive force;

b) Tensile force;

c) Shear force; and

d) Flexural and torsional moments, as applicable.

8.1.1 *Transfer of Compressive Force*

8.1.1.1 The precast or cast in-situ member supporting the other elements shall be designed to safely resist all the compressive forces generated by various load combination.

8.1.1.2 The joint shall be designed for all other forces arising from the external forces along with the predominant compression. Shear forces more than 0.1 P_u (axial load) shall not be neglected in the design of the joint.

8.1.1.3 The members may rotate because of temperature change, creep and shrinkage, hence bearing pads or strips shall be provided to account for the rotation. Minimum thickness of the joint shall be decided based on tolerance requirements, and shall not be less than 10 mm.

8.1.1.4 Appropriate edge distance for the bearing pad shall be provided to avoid crushing or cracking of edges.

8.1.1.5 Connection having bearing materials harder than concrete shall be checked for ultimate limit state as per the provisions of good practice [C-7(2)]. Busting reinforcement shall be provided in the supporting member, if required.

8.1.1.6 Connection having bearing materials softer than concrete shall be checked for serviceability limit states as per the provisions of good practice [C-7(2)]. Splitting reinforcement shall be provided in the supporting member, if required.

8.1.1.7 Joint using steel inserts for connection shall be properly designed and executed as per the design requirements. The steel components shall be anchored to the concrete members for proper transfer of compressive forces to the main reinforcement.

8.1.1.8 Connections shall be provided with reinforcement as follows or with equivalent connection:

a) For walls elements, dowels shall be placed at a maximum spacing of 1/4th of the length of the wall panels or 450 mm or as required by design. Also, at least two extreme edge dowels shall be continuous from foundation till roof using Class H coupler as per [C-7(9)] or any other connection;

b) For column minimum four corner bars of 12 mm diameter or as per design requirements shall be continuous from foundation till roof using Class H coupler as per [C-7(9)] or any other connection;

c) For beam at least one 12 mm dowel at centre of the bearing region of the beam shall be provided to avoid accidental failure; and

d) For any other member appropriate reinforcement shall be provided to avoid accidental lateral loads.

8.1.2 *Transfer of Tensile Forces*

8.1.2.1 Tensile forces generated at the joint shall be resisted by tie bars sufficiently anchored at both the sides of the joint.

8.1.2.2 Adhesive bond between the members shall not be accounted in force transfer.

8.1.2.3 The tensile stresses generated in the connecting members shall also be linked to the reinforcement of the member by proper provision of ties or any other connection.

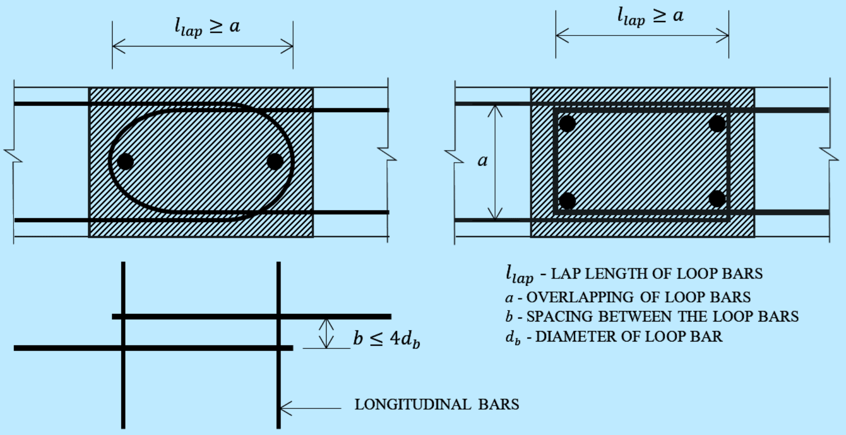
8.1.2.4 Premature brittle failure shall be avoided for tie members and material selected for making tie shall be ductile.

8.1.2.5 Joints with grout filled tubes or sleeves shall be utilised with adequate development length. International practice indicates that the confinement of dowel tube enhances the rebar anchorage performance, reducing the required development length. Hence, for determining development length reduced development length shall be adopted based on test results as per 12. In absence of test results, the bond strength of concrete shall be considered. Alternatively, other joint configurations may be adopted, provided their performance is evaluated through assemblage and system level testing along with nonlinear analysis and approved from competent authorities or institutes of repute.

8.1.2.6 A joint using bolting, welding or lap splicing shall be properly anchored to the precast components and transfer of forces in the member shall be verified.

8.1.2.7 Reinforcement loops (U-bars) protruding from precast elements may be used to provide tie between the elements as shown in Fig. 30. Reinforcement of 8 mm or higher diameter shall be provided as longitudinal reinforcement (preferably four numbers with U-bars) as shown in the Fig. 30. Lap length, spacing of loop bars and overlapping length shall be as per the Fig. 30.

8.1.2.8 Anchoring of reinforcement shall be such that high stress concentration in the members are avoided.



$l_{lap} \geq a$
$l_{lap} \geq a$
a
$b \leq 4d_b$
l_{lap} - LAP LENGTH OF LOOP BARS
a - OVERLAPPING OF LOOP BARS
b - SPACING BETWEEN THE LOOP BARS
d_b - DIAMETER OF LOOP BAR
LONGITUDINAL BARS

FIG. 30 REINFORCEMENT LOOP JOINT FOR TRANSFERRING TENSION

8.1.3 *Transfer of Shear Force*

8.1.3.1 Shear forces may be transferred between concrete elements by adhesion or friction at joint interfaces, shear-key effect at indented joint faces, dowel action of transverse steel bars, pins and bolts, or by other mechanical connection devices. The frictional resistance can be enhanced by the pull-out resistance of tie bars properly placed across the joint.

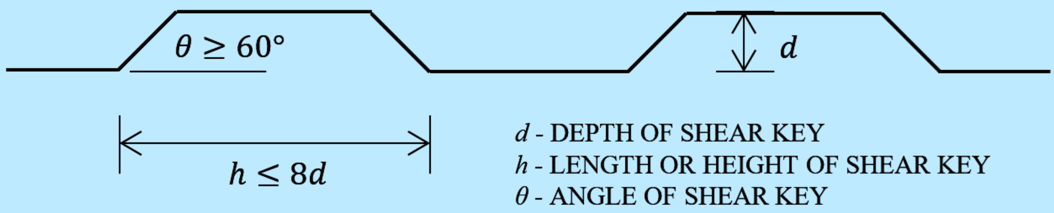
8.1.3.2 Adhesive bond or adhesion between the interfaces of elements shall not be considered in the calculation of shear strength of the joint.

8.1.3.3 Shear resistance of joint between two elements with reinforcement may be calculated using shear friction (*see* 7.12) equation or as per good practice [C-7(2)]. Shear friction shall not be used if the reinforcement crossing the joint is subjected to compressive forces by the displacement of the members.

8.1.3.4 Permanent compressive stresses acting on the joint shall also be considered along with shear friction.

8.1.3.5 Unreinforced shear keys or castellation or indented joint face shall be used for members subjected to very high shear forces. This connection shall be designed to remain elastic under ultimate limit states to avoid sudden brittle failure of the joint. Transverse reinforcement across the interfaces shall be provided to prevent sudden separation of the members.

8.1.3.6 The dimension of shear keys shall be as per Fig. 31.



$\theta \geq 60°$
d
$h \leq 8d$
d - DEPTH OF SHEAR KEY
h - LENGTH OR HEIGHT OF SHEAR KEY
θ - ANGLE OF SHEAR KEY

FIG. 31 DETAILING OF SHEAR KEY WITHOUT REINFORCEMENT

8.1.4 *Transfer of Bending and Torsional Moment*

8.1.4.1 Strong connections shall be used possessing stiffness, strength and ductility confirming to that of cast in-situ construction.

8.1.4.2 Moment resisting connections shall be designed such that ductile failures occur without any local modes of brittle failure (shear, pull-out, etc).

8.1.4.3 Continuity within the joint may be obtained by any of the following or combination:

a) Lapping of bars;

b) Reinforcement grouted into apertures;

c) Overlapping loop or U-bars;

d) Reinforcement connected using threaded couplers; and

e) Any other type of connection with appropriate testing of the connection.

8.2 Connection Based on Precast Concrete Seismic Systems

The connection of seismic moment resisting frames and structural walls incorporating precast concrete elements generally fall into two broad categories, either ‘equivalent monolithic (emulative)’ systems or, ‘jointed’ systems. The distinction between these types of construction is based on the design of the connections between the precast concrete elements as provided in the following sections.

8.2.1 *Equivalent Monolithic Systems* (*Emulative*)

A precast concrete structural system satisfying the requirements of this clause shall have strength and toughness equivalent to that provided by a comparable monolithic reinforced concrete structure.

8.2.1.1 *Connections in monolithic systems*

The connections between precast concrete elements of equivalent monolithic systems can be subdivided into two categories:

a) *Strong connections of nominal ductility*

In moment resisting frames and structural walls these connections are protected by a capacity design approach which ensures that flexural yielding occurs away from the connection region.

b) *Ductile connections*

Ductile connections of equivalent monolithic systems typically comprise longitudinal reinforcing bars in the connection which are expected to enter the post-elastic range in a severe earthquake.

In moment resisting frames yield penetration may occur into the connection end-region. The potential plastic hinge region may extend a distance along the end of the member as in cast-in-place construction.

8.2.2 *Jointed Systems*

This system is not in the purview of this NBCS.

8.3 Design of Connections

The design of connections shall follow those design methods and considerations for reinforced concrete, prestressed concrete and structural steel. Proprietary connections shall be based on tests and approved from competent authority or institutes of repute. The following types are the broad category of the connections based on connecting members:

a) Column to foundation;

b) Column to column;

c) Beam to column;

d) Beam to beam;

e) Beam to slab;

f) Beam to wall;

g) Wall to wall;

h) Wall to slab; and

j) Slab to slab.

Examples of typical connections are shown in Annex E. These connections are for illustrative purposes only. In all instances, the design should demonstrate that the connections are able to resist the applied structural actions. Where appropriate, the suitability of the connection to act as a pinned or moment connection is highlighted. The location of the connections for a framed structure shall be as per **6** (Fig. 2, Fig. 3, Fig. 4 and Fig. 5).

8.3.1 *Detailing of Reinforcement*

The following shall be considered:

a) *Lapping of bars* — Where bars passing through the connection are lapped to provide continuity of reinforcement, the recommendations good practice [C-7(2)] and integrity tie requirements shall be followed;

b) Reinforcement grouted into aperture — An adequate capacity should be provided for grouted reinforcing bars to prevent pull-out. Embedment length shall be as per manufacturer guidelines, however testing shall be carried out as per **12**. If grouted tube is used, the embedment length of dowel shall be at least 300 mm or as required by design, whichever is higher;

c) *Reinforcement loops* — Loop reinforcement shall be provided as per **8.1.2** and Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS;

d) *Couplers* — Reinforcement may be connected by couplers. The concrete cover to the couplers (other than grouted tube or duct) shall be at least 25 mm or as per specifications of the project. A locking device should be used for threaded coupler connections where there is a risk of the threaded connection working loose, for example during vibration of in-situ concrete. Reference should be made to [C-7(9)] and the manufacturers' technical specifications for guidance and acceptance criteria for the usage. Testing of couplers shall be as per **12** and relevant guidelines of [C-7(9)]. When the system is part of lateral force resisting system, the grout strength shall not be less than 90 MPa and testing shall be carried out as per **12** by the supplier of the coupler or as agreed upon by the project team. Modify to mention 12 for LFRS and 7(9) for regular coupler without lateral force; and

e) *Welding of bars* — When bars are connected by welding, the connection shall ensure full capacity of the bar is achieved and failure of weld is avoided. Testing of the welded samples shall be as per relevant standards. Welding of rebar shall be avoided for normal circumstances, to be used for repair or strengthening of a connection, if required.

8.3.2 *Connections in Compression*

8.3.2.1 The design of connections in tension shall follow the guidelines of 8.1.1.

8.3.2.2 In normal circumstances, the area of concrete to be utilized for calculating the strength of the connection in a wall or column should be the greater of:

a) 75 percent of the area of contact between the wall or column and connection; or

b) The area of the in-situ concrete excluding the part of any intruding slab or beam units. However, those parts of the floor slab or beam units that are solid over the bearing may be included in calculating the strength and such units should be properly bedded on concrete or mortar of adequate quality. This area should not be taken as greater than 90 percent of the wall or column area.

8.3.3 *Connections in Tension*

8.3.3.1 The design of connection in tension shall follow the guidelines of 8.1.2.

8.3.3.2 Stirrups shall be placed along the lap length, for the connection utilizing lapping of bars, grouted duct, or grouted coupler for transfer of tensile forces.

8.3.3.3 Welding or bolting shall be used with appropriate design. The embedded inserts shall be appropriately anchored to the primary member.

8.3.4 *Connection in Shear*

8.3.4.1 The design of connection in shear shall follow the guidelines of 8.1.3.

8.3.4.2 A shear connection may be considered effective, if the connection is grouted with a suitable concrete or mortar mix of strength of at least 5 MPa higher than the connecting members and the criteria of 8.1.3 is satisfied.

8.3.4.3 For joints subjected to minimal shear between wall panels or thin members, looped wire ropes shall be used to connect between the members with a maximum spacing of 450 mm. These connections shall not be used in lateral force resisting system and in transfer of seismic forces.

8.3.4.4 Transfer of forces solely by friction caused due to gravity load shall not be used.

8.3.5 *Bond*, *Anchorage*, *Bearing*, *Laps*, *Joints and Bends in Bars*

8.3.5.1 Provision of bond, anchorage, bearing, laps, joints and bend in bars shall be as follows:

a) *Avoidance of bond failure due to ultimate loads* — At both sides of any cross-section the force in each bar should be developed by an appropriate embedment length or other end anchorage;

b) *Anchorage bond stress* — Anchorage bond stress (τ_b) is assumed to be constant over the effective anchorage length. It may be taken as the force in the bar divided by its effective surface anchorage area, as given below:

$$\tau_b = \frac{F_s}{\pi \varphi_E L}$$

where

τ_b = bond stress;

F_s = force in the bar or group of bars;

φ_E = effective bar size which, for a single bar is equal to the bar size and, for a group of bars; and

L = anchorage length.

c) *Values for design ultimate anchorage bond stress* — Values for design ultimate anchorage bond stress τ_{bu} may be obtained from the equation. The anchorage bond stress (τ_b) shall not exceed the design ultimate anchorage bond stress:

$$\tau_{bu} = \beta\sqrt{f_{cu}}$$

where

τ_{bu} = design ultimate anchorage bond stress; and

β = a coefficient dependent on the bar type.

The values of β may be taken from Table 11. These values include a partial safety factor (γ_m) of 1.4.

Table 11 Values of Bond Coefficient β

[*Clause* 8.3.5.1(c)]

Sl No.	**Bar Type**	β	
		Bar in Tension	Bar in Compression
(1)	(2)	(3)	(4)
i)	Plain bar	0.28	0.35
ii)	Deformed bar	0.4	0.63

8.4 Connections Other than Those Involving Continuity of Reinforcement

8.4.1 *Joints with Structural Steel Inserts*

Joints with structural steel inserts generally consist of a steel plate or rolled steel section projecting from the face of a column to support the end of a beam. The reinforcement in the ends of the supported member shall be designed in accordance with the provisions mentioned in Part C/Section 5 of this NBCS. Detailed design provisions shall include the following:

a) The steel sections and any bolted or welded connections should be designed in accordance with the appropriate recommendations;

b) Design ultimate bearing stresses shall be as per **7.11**; and

c) Consideration should be given in the design to the possibility of vertical splitting under the steel section because of shrinkage effects and localized bearing stresses, for example under narrow steel plate.

8.4.2 *Resin Adhesives*

Resin adhesives may be used to form joints subjected to compression but not to resist tension or shear. These adhesives should only be used where they are adequately protected against the effects of fire.

8.4.3 *Other Types of Connections*

Any other type of connection that can be shown to be capable of carrying the ultimate loads acting on it may be used. Amongst those suitable for resisting shear and flexure are those made by prestressing across the joint.

8.5 Structural Integrity and Progressive Collapse

Reinforcement and connections shall be detailed to tie the structure together effectively maintaining adequate structural integrity and to prevent progressive collapse. Integrity ties shall be followed in accordance with the following clauses. Figure 32 shows the typical arrangements of integrity ties in a large panel structure and frame structure. Progressive collapse requirements shall be as per **8.5.10**.

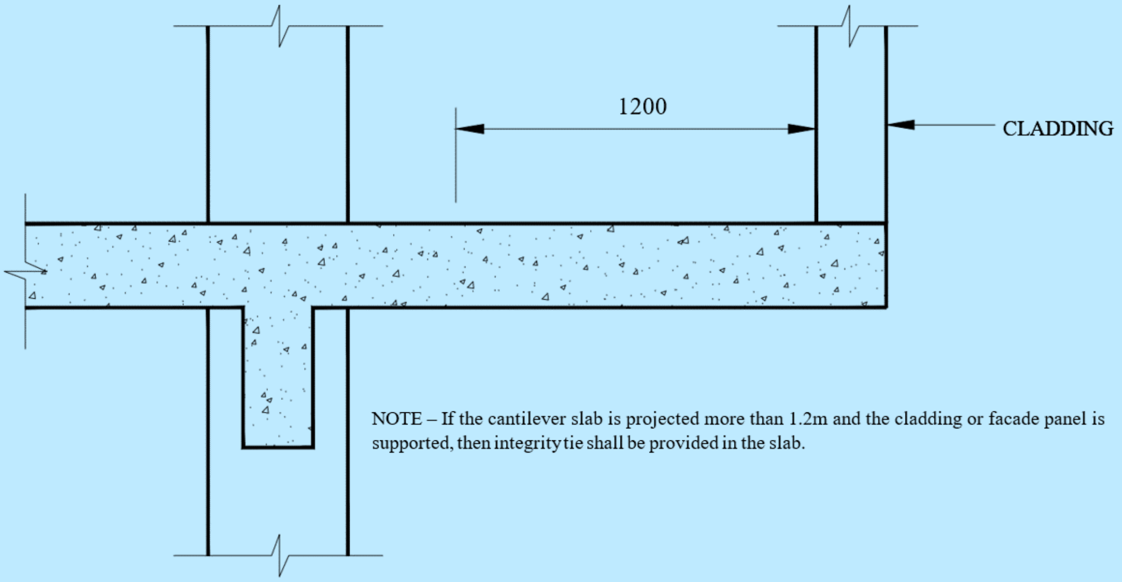
FIG. 32 TYPICAL ARRANGEMENT OF INTEGRITY TIES

8.5.1 *Peripheral Ties*

At each floor and roof level an effectively continuous tie shall be provided within 1.2 m of the edge of the building or within the perimeter wall (*see* Fig. 33). The tie shall be capable to resist a tensile force of F_t equal to 60 kN or (20 + 4N) kN, whichever is less, where N is the number of storeys (including basement).



1200
CLADDING

NOTE – If the cantilever slab is projected more than 1.2m and the cladding or facade panel is supported, then integrity tie shall be provided in the slab.

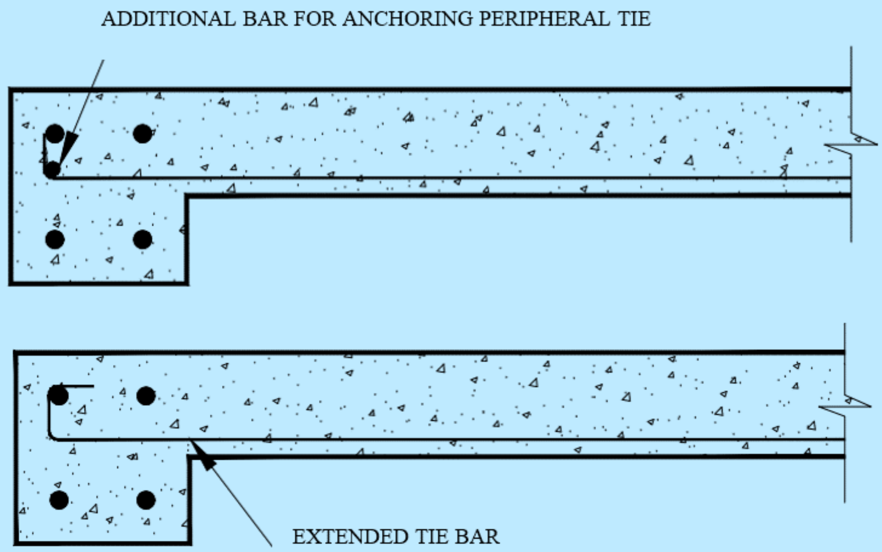
FIG. 33 POSITION FOR PERIPHERAL TIE

8.5.2 *Internal Ties*

These shall be provided at each floor and roof level in two directions approximately at right angles. Ties shall be effectively continuous throughout their length and be anchored to the peripheral tie at both ends, unless continuing as horizontal ties to columns or walls (*see* Fig. 34). The tensile strength, in kN/m width shall be the greater of:

$$\left(\frac{g_k+q_k}{7.5}\right)\frac{L_rF_t}{5}\ and\ F_t$$

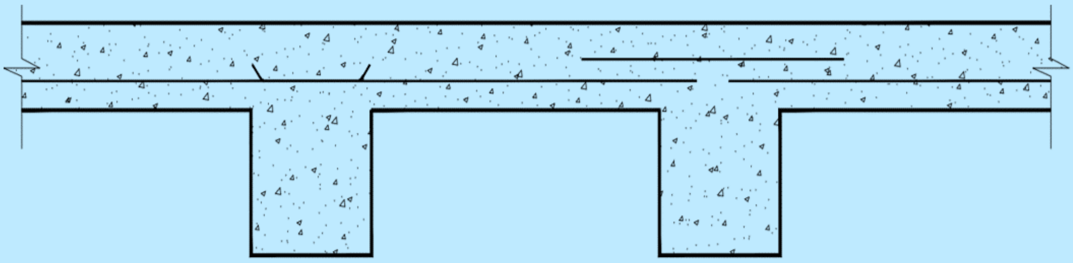
where, $(g_k + q_k)$ is the sum of average characteristic dead and imposed floor loads, in kN/m^2 and L_r is the greater of the distance between the centre of columns, frames or walls supporting any two adjacent floor spans in the direction of the tie under consideration.



NOTE – If the peripheral tie consists of bars in an edge beam, then the bottom bars in the slabs will not be at the same level as the peripheral tie bars. It is suggested that either an additional bar be used for anchoring in the peripheral tie or the internal tie bars be extended and anchored around the top bar in the beam.

FIG. 34 ANCHORING OF TIES IN SLABS

The bars providing these ties shall be distributed evenly in the slabs (*see* Fig. 35) or shall be grouped at or in the beams, walls or other appropriate positions but at spacing generally not greater than 1.5 L_r.



NOTE – For continuity in continuous slabs, bars are distributed evenly in a floor slab by means of lapping some bottom slab reinforcement at supports, either by extending existing bars or by an addition of splice bar.

FIG. 35 CONTINUITY REQUIREMENT FOR SLAB

8.5.3 *Horizontal Ties to Column and Wall*

All external load-bearing members such as columns and walls shall be anchored or tied horizontally into the structure at each floor and roof level. The design force for the tie shall be greater of:

a) $2F_t$ kN or $Ls \times (F_t/2.5)$ kN, whichever is less for a column or for each metre length, if there is a wall (Ls is the floor to ceiling height in metre); and

b) 3 percent of the total ultimate vertical load in the column or wall at that level.

For corner columns, this tie force should be provided in each of two directions approximately at right angles.

8.5.4 *Vertical Ties*

Each column and each wall carrying vertical load should be tied continuously from the foundation to the roof level.

8.5.4.1 The reinforcement provided is required to resist a nominal tensile force of at least 50 kN per horizontal metre of wall.

8.5.4.2 At least two integrity ties shall be provided in each wall panel.

8.5.4.3 Connection between precast column shall have vertical integrity ties, with a nominal tensile strength of $1.4A_g$, where A_g is the gross area of the column. For column with larger cross section reduced effective area equal to the actual cross section required shall be used. However, the reduced area shall be at least one-half of the gross area of column.

8.5.4.4 In situation where provision of vertical ties cannot be done, the element should be removed, and the surrounding members shall be designed to bridge the gap.

8.5.4.5 All members in the lateral force resisting system shall have one tie continuous from foundation to terrace at each end of the member with Class H coupler as per [C-7(9)] (ties as per design) or direct lapping (ties as per lapping requirements).

8.5.5 *Tie Anchorage*

A tie crossing another tie at right angles may be considered anchored if the bars extend 12 times the bar diameter or an equivalent anchorage beyond the other tie; or an effective anchorage length, calculated from the tension force, beyond the centreline of the other tie. At abrupt changes in construction or at re-entrant corners, it shall be ensured that the ties are sufficiently anchored or to be made effective by other means.

8.5.6 *Continuity of Ties*

A continuous tie shall satisfy **8.3.1**. The minimum thickness of in-situ concrete section where tie bars are provided shall be at least the total dimension of the bar diameter (or two diameters at laps) and twice the maximum aggregate size plus 10 mm.

To provide continuity, the tie shall also satisfy one of the following:

a) A bar in a precast concrete unit lapped with a bar encased in in-situ concrete bounded on two opposite sides by rough faces of the same precast unit (*see* Fig. 36);

b) A bar in a precast concrete unit lapped with a bar encased in the topping of in-situ concrete tied to the precast unit by links or stirrups. The tensile resistance of such links and stirrups should not be less than the designed tension in the tie (*see* Fig. 37); and

c) Bars lapped within in-situ topping concrete with projecting links or stirrups from the supporting precast units, such as beams or slabs (*see* Fig. 38).

8.5.7 *Ties between Precast Element and Topping*

In potential plastic hinge regions, the consequences of delamination of the topping from the precast members shall be assessed. If the maximum shear stress at any section exceeds 0.4 MPa, connectors shall be provided between the topping and precast to achieve composite action as per the following guidelines:

a) Ties with an effective area of 40 mm^2 per m^2 of floor area, or equivalent connectors, shall connect the topping to the precast element;

b) Spacing of connectors shall not exceed 1 500 mm and the tributary area of topping reliant on each connector shall not exceed 2.25 m^2;

c) Connectors shall engage horizontal reinforcement, or shall be otherwise effectively anchored into both the topping and the precast element, or into the joints between precast elements; and

d) In HCS appropriate connection shall be placed in slab joints.

8.5.8 *Anchorage in Structures*

All precast floor and precast roof units should be effectively anchored if these units are not utilised to provide the ties. The anchorage shall be capable of supporting the dead weight of the precast unit to that part of the structure which contains the ties.

8.5.9 *Eccentricity*

Ties connecting precast floor or roof units shall be so designed and placed as to minimise eccentricity.

8.5.10 *Anchorage at supports*

In case reinforcing bars are used to provide the structural integrity of slab ends supported on corbels or nibs, great care shall be taken to ensure it is adequately lapped and anchored. Allowance should also be made for constructional inaccuracies.

8.5.11 *Progressive Collapse*

The following recommendations shall be followed for ensuring stability of prefabricated structures:

a) Adequate strengthening of external joints of external wall panels is important since these elements are not fully restrained on both sides by floor panels. Adequate design precautions shall be taken.

Connections for the external wall panels are likely to be the weakest points of a precast panel building, if not designed properly;

b) Restraint shall be provided to all load bearing elements at the corners of the building. These elements and the external ends of cross-wall units shall be stiffened either by introducing columns as connecting units or by jointing them to non-structural wall units, which in emergency shall act in force transfer;

c) In prefabricated construction, the possibility of gas or other explosions which can damage primary structural elements leading to progressive collapse of the structure shall be considered. It is, therefore, necessary to consider the possibility of progressive collapse in which the failure or displacement of one element of a structure causes the failure or displacement of another element and results in the partial or total collapse of the building;

d) Provision in the design to reduce the probability of progressive collapse is essential in buildings of height more than 15 m and is of relatively higher priority than for buildings of lower height. However, buildings of special importance shall be checked for progressive collapse irrespective of height guidelines. One way of preventing progressive collapse of external wall panels is to design the combined precast wall panels of entire width as a beam of depth equal to the floor height for the impact loading of upper floors and provide reinforcement accordingly at the top and bottom of all precast wall panels at each floor. To make reinforcement continuous across joints, top and bottom bars projected into joints between wall panels shall be joined with lapping bars;

e) It is necessary to ensure that any local damage to a structure does not spread to other parts of the structure remote from the point of mishap and that the overall stability is not impaired, but it may not be necessary to stiffen all parts of the structure against local damage or collapse in the immediate vicinity of a mishap, unless the design briefs specially require this to be done. The requirements as specified at **8.5** shall be followed to prevent progressive collapse of the structure;

f) Additional protection may be required in respect of damage from vehicles. Further, it is necessary to consider the effect of damage to or displacement of a load-bearing member by an uncontrolled vehicle. It is strongly recommended that important structural members are adequately protected by concrete kerbs or similar method. In areas with possibility of passenger vehicular impact, the precast components shall be designed for an un-factored load of 27 kN, in any direction, acting at heights between 450 mm and 700 mm on an area not larger than 300 mm × 300 mm to produce maximum load effect. This load is not required to act concurrently with any handrail or guard rail system loads; and

g) In all aspects of erection that affect structural design, it is essential that the designer shall maintain a close liaison with the builder/contractor regarding the erection procedures to be followed.

8.5.12 *Key Element*

For buildings of five or more storeys, the layout should be checked to identify key elements. A key element is such that its failure would cause the collapse of more than a limited area close to it. The limited area defined above may be taken equal to 70 m^2 or 15 percent of the area of the storey, whichever is less. If key element exists, it is preferable to modify the layout so that the key element is avoided or design the element for a force of 36 kN/m^2.

8.6 Miscellaneous Items for Joints

8.6.1 *Sealants for Joints*

In choosing the appropriate type of sealant for the joints, consideration should be made in respect of the movements between the components to be joined, the bond that is achievable between the components and the sealant and the nature of the sealing material itself. Hybrid, PU (polyurethane, polysulphide), silicone based, or any other sealant shall be used depending on requirements.

8.6.2 *Joint Width*

Joint widths should be sized to accommodate construction tolerances and movements without overstressing the jointing material. Irrespective of movement, a joint width of 10 mm is the minimum practicable for sealant application.

8.6.2.1 Minimum width of joint between the erected elements or supporting elements shall be as follows:

a) 10 mm, if not specified;

b) 20 mm for wall elements;

c) 30 mm for column elements; and

d) For larger elements as per grouting requirements but shall preferably not exceed 50 mm.

8.6.3 *Joint Preparation*

Satisfactory performance is critically dependent on the satisfactory adhesion of the sealant to the joint surfaces. Primers may be recommended by the manufacturer for some materials. Formwork oils, curing compounds, silicone waterproofing admixtures and surface coating materials may reduce bond and require special precautions.

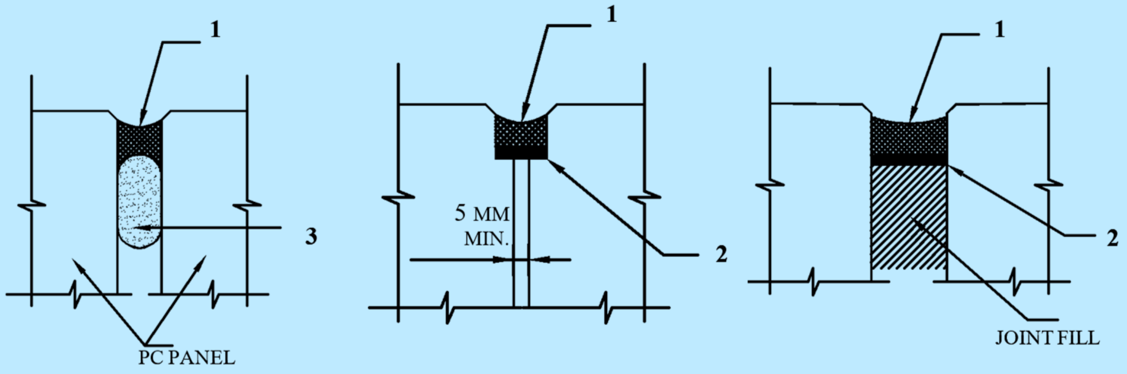
Water jetting, sand blasting, wire brushing or the use of retarder may be required to prepare the concrete joint surfaces in certain instances. Consideration should be given to the use of chamfers to reduce edge damage.

8.6.4 *Back up Material and Bond Breaker*

To ensure good adhesion, a firm backing should be provided for the application of sealants. The required shape and proportions of the sealant are achieved by the correct installation of the back up material.

Sealants in movement joints should not adhere to the backing material to avoid any unnecessary restraint. To ensure that the sealant and back up materials, bond breakers and joints fillers are compatible and appropriate for the proposed end use, advice from the manufacturer should be obtained as necessary.

The sealant backing may be provided by a closed cell foam back up material alone (*see* Fig. 39A), a thin self-adhesive bond breaker tape (*see* Fig. 39B) or a joint filler separated from the sealant by a thin self-adhesive bond breaking tape (*see* Fig. 39C).



39A CLOSED CELL FOAM BACKING

39B) BOND BREAKER TAPE BACKING

39C) JOINT FILLER WITH BOND BREAKER TAPE

1 - SEALANT,
2 - BREAKER TAPE OR BOND BREAKER
3 - BACKER ROD

FIG. 39 BACK-UP MATERIALS AND BOND BREAKERS IN MOVEMENT JOINTS

8.6.4.1 *Minimum joint gap widths*

For elastic sealants, the minimum thickness shall be 5 mm, the ratio of width to thickness should never exceed 1 : 1 and for optimum performance 2 : 1.

8.6.4.2 *Sealant application*

High moisture content may be detrimental to the adhesion of the sealant. Sealing should not be undertaken if there is free water present on the surface of the concrete.

8.6.4.3 *Performance, choice and failure of sealant*

The magnitude of the movement, and also the mode, frequency and rate of movement affect the performance of a sealed joint.

There are many factors affecting the choice of sealant suitable for different types of movement. However, as a general rule, joints which have to accommodate frequent and rapid movement need an elastic sealant, while joints in massive components, with high thermal inertia resulting in much slower movement, may be satisfactorily sealed with an elastoplastic, plasto-elastic or a plastic sealant.

The different ways in which sealants can fail as a consequence of different factors including climatic conditions, environmental factors, substrate incompatibility, abrasion and traffic loading need to be considered when selecting a sealant.

8.6.5 *Sealing Strips*

Preformed sealing strips of appropriate sizes and sections shall be used as required. There are two basic types:

a) Mastic strips; and

b) Impregnated or coated cellular strips.

8.6.5.1 *Mastic strips*

These should be normally installed during the assembly of components. They require an initial compression to ensure proper adhesion to the components forming the joint. As a degree of compression is also required during in service, mastic strips should not be used for joints which open beyond their assembled size.

8.6.5.2 *Impregnated or coated cellular strips*

Impregnated or coated cellular strips may be supplied in a pre-compressed form, and one face may be adhesive coated. When pre-compressed, they can readily be installed within the joint gaps, but should be of a suitable size to be maintained under the degree of compression specified by the manufacturer throughout the range of joint movements. The degree of compression may be varied according to the level of sealing performance required.

To ensure uniformity of compression and stability of the seal, it is important that the joint faces are parallel. Sufficient joint depth shall be provided to accommodate the seal with these depths to width ratios. For external applications, sealing strips should have adequate exposure resistance for the proposed service conditions.

8.6.6 *Joint Fillers*

Fillers for movement joints should be carefully selected to suit their intended use. To ensure that the sealant and filler are compatible, advice from the manufacturer should be sought. Fillers should be non-absorbent with appropriate elastic properties and fire resistant.

8.6.7 *Overlapping of Precast Facade*

The resistance to water penetration between the upper and lower panel of precast facade is commonly provided by an upstand profile. A minimum overlap of 75 mm between the upper and lower panel is recommended.

9 CONSTRUCTION PLANNING

9.1 Pre-Engineering and Design Coordination

9.1.1 *Importance of Pre-Engineering*

Pre-engineering plays a critical role in the planning and execution of any precast concrete project. To ensure a successful outcome, the planning engineer should begin working from the design stage to ensure proper production, installation, connections, and logistics. Key resources must be identified and prepared for each phase of the project, including:

a) Availability land/approvals/water and electricity for a site-based factory;

b) Suitable plant and machinery;

c) Steel moulds;

d) Lifting machinery at factory;

e) Trailers;

f) Lifting machinery on site (tower cranes/mobile cranes); and

g) Site access for transportation of large elements as well as route studies and local regulations and hours for operating large trailers.

9.1.2 *Resource Planning and Feasibility Factors*

The resources should be carefully planned based on the types of project elements and their quantities. The engineer is also responsible for reserving these resources throughout the project duration. Key feasibility considerations include:

a) *Building geometry* — Ensure shapes and geometry are as symmetrical and regular as possible;

b) *Grid-lines* — Column and wall locations should, preferably, follow a standardized pattern;

c) *Height clearances* — Consideration of clear height expectations between beams and slabs;

d) *Grid spacing* — Optimize grid spacing to take full advantage of precast elements; and

e) *Standardization* — Standardize elements within one floor and across multiple floors when feasible.

9.1.3 *Pre-Engineering Design Stage Process*

The pre-engineering design stage should include the following steps:

a) Study of building functionality;

b) Load assumptions and calculations;

c) Preparation of the design basis report (DBR);

d) Structural analysis;

e) Preliminary framing plan selection for precast elements;

f) Approval of preliminary framing plans by the architect/client;

g) Review meetings with architects and consultants;

h) Finalization of the structural framing plan after incorporating feedback and value engineering;

j) Release of the good for construction (GFC) and structural framing plan (R0), including:

    1) Geometry of precast elements;

    2) General arrangement (GA) drawings with reinforcement details; and

    3) Connections and inserts.

k) Coordination with mechanical, electrical, plumbing and other service consultants should occur during the early stages.

9.2 Project Planning, Scheduling and Monitoring

9.2.1 *Production Planning*

Careful planning is essential for ensuring that precast concrete systems are produced efficiently. Key factors to address include:

a) Synchronization of manufacturing schedules and resources to meet construction and storage needs;

b) Anticipation of any special transportation or access challenges;

c) Use of detailed production shop drawings to facilitate smooth execution; and

d) Factory curing periods for high strength concrete elements.

9.2.1.1 *Shop drawings*

Shop drawings should contain:

a) Member shapes (elevations and sections) and dimensions;

b) Details of reinforcement, anchors, inserts, etc;

c) Connection details;

d) Production tolerances;

e) Handling and lifting devices;

f) Finishing and bearing seat details;

g) Transportation and storage methods; and

h) Unique identification of elements (ID, location and orientation).

9.2.1.2 *Factory vs on-site production*

A decision whether precast elements should be produced in an off-site factory or on-site, based on factors such as:

a) Project scale and volume;

b) Availability of factory space near the site;

c) Contractual agreements regarding space provision;

d) Element type, weight, and size; and

e) Cost-benefit analysis.

9.2.2 *Production Schedule*

9.2.2.1 *Cycle time and throughout rate and the key aspects*

a) *Cycle time* — refers to the total time to complete one production cycle of an element, from mould preparation to quality checks and delivery; and

b) *Throughput rate* — refers to the rate of production (units per day, week, or month).

9.2.2.2 *Developing the production schedule*

A production schedule developed based on the following:

a) Splitting the floor plan into various ‘installation parts’, typically aligned with crane locations and capacities;

b) Estimation the number of elements per part and the installation duration for each part based on element type and connection complexity;

c) Using historical data and experience to estimate installation cycle times for each element;

d) Assigning unique element IDs to each installation part and sequence them accordingly;

e) Publishing a sequence chart that includes:

    1) Planned drawing release date;

    2) Planned casting date;

    3) Planned transportation date; and

    4) Planned installation date.

9.3 Project and Factory Logistics Planning

9.3.1 *Haulage Planning*

Transportation constraints influence the size and shape of precast elements. The following factors should be considered in haulage planning:

a) Trailer lengths (standard lengths of 6 m, 12 m, with special cases up to 30 m);

b) Trailer width (typically between 2.4 m to 2.7 m);

c) Height clearance (3.6 m to 4 m, adjustable with low-bed trailers);

d) Weight capacity (25 MT to 35 MT);

e) Special permits for oversized loads that may be needed;

f) Route surveys and permissions to be obtained if crossing bridges or navigating urban areas; and

g) Large element transportation time slots through day/night as per local regulations.

9.3.2 *Factory Stockyard and Logistics Coordination*

Precast elements in the factory stockyard should be stored using first in, first out (FIFO) or last in, first out (LIFO) methods, depending on site requirements. Proper stock registers and inventory management software should be used for efficient tracking and organization. Storage size of the yards should be defined by the minimum concrete strength and curing periods.

9.3.3 *Crane Planning*

A comprehensive crane layout should be developed in collaboration with the installation planning engineers considering the following:

a) Types of cranes (tower cranes, mobile cranes);

b) Site constraints (space, access);

c) Ground strata for crane footing;

d) Lifting capacities and feeding locations;

e) Crane removal and repositioning areas; and

f) Double handling constraints due to storage at site or crane reach.

9.4 Installation Sequence

Once the casting sequence is set, installation dates to each element should be assigned based on factors such as:

a) Crane type and operational speed;

b) Reduced crane efficiency where multiple cranes are deployed with overlapping zones;

c) Element type and installation cycle time;

d) Connection complexity;

e) Grouting and curing durations;

f) The number of shifts and crane operation hours; and

g) Adjustment of installation dates and resources as needed based on available machinery and logistics.

9.5 On Site Work Planning

9.5.1 *Surveying*

The first activity on-site is surveying and line-out. It should be ensured that key points are marked, including:

a) Building corners and faces;

b) Compound wall boundaries;

c) Grid lines and column centres;

d) Footing corners;

e) Shear wall grid lines; and

f) Site constraints such as high-tension lines or existing canals or water bodies or filled up areas or marsh lands.

9.5.1.1 Drone surveys are recommended for more accurate and automated site measurements, which also help in tracking progress.

9.5.2 *Cast-In Situ Works*

Cast in-situ (CIS) work is crucial in precast projects. The interface between precast and CIS activities typically occurs during installation and connection phases. The interfaces of the joints shall be roughened to ensure proper bonding with the CIS concrete or grout. Minimizing inter-trade dependencies improves project success in terms of both time and cost. This interface also needs careful attention, as the dowels projecting from precast elements may have higher variation that affects precast installation. Detailed as-built surveys must be completed well in advance to avoid last minute repairs and long delays.

9.6 Digital Tracking and Monitoring Tools

To enhance precision and efficiency, building information modelling (BIM) may be implemented for both production and assembly of precast elements. This technology supports:

a) Access to real-time drawing by all engineers, reducing errors;

b) Seamless use across production, installation, and progress monitoring stages; and

c) Required infrastructure such as Wi-Fi network and system access between various agencies are be in place.

10 CONSTRUCTION, MANUFACTURE, STORAGE, TRANSPORT AND ERECTION OF PRECAST ELEMENTS

10.1 Manufacture of Precast Concrete Elements

10.1.1 A precast facility shall be located based on proximity to raw materials, logistics infrastructure, storage capacity, and crane access to ensure economic production and streamlined erection.

10.1.2 *Manufacture*

Precast elements may be manufactured at a permanent factory or temporary site facility, selected based on project scale, logistics, and environmental goals. For reduction in site pollution and wastage to achieve sustainability in precast construction a reference may be made to G-4.

10.1.2.1 *Factory prefabrication*

Factory prefabrication involves the commercial production of standardized components in a factory setting, typically for long-term manufacturing. It is a capital-intensive process where work is carried out year-round, ideally under a covered shed to minimize the impact of seasonal variations. This type of facility allows for high levels of mechanization, with production organized in a factory-like manner, supported by a consistent team of workers.

10.1.2.2 *Site prefabrication*

Site prefabrication refers to the production of precast components at or near the construction site and shall be adopted for large-scale or long-duration projects where it offers measurable advantages in transportation cost and productivity. Although temporary, the site factory should be comparable to a permanent facility with strict quality control. There are the following two types of site prefabrication:

a) *Semi-mechanized* — Carried out in open areas using primarily local labour, with minimal equipment; moulds may be stationary or mobile, and the level of skill shall be appropriate to the component complexity; and

b) *Fully-mechanized* — Conducted within covered sheds using skilled labour and factory-grade machinery, designed for high-volume and high-quality precast production.

10.1.2.3 *Precast factory quality audits*

All precast production facilities shall undergo quality audits at least annually. Audits shall be conducted by a competent team jointly approved by the contractor and client. Audit scope shall include production quality, safety and documentation.

10.1.3 The manufacturing of precast elements shall involve three categories of processes: core, auxiliary and subsidiary. Each category shall be planned and coordinated to ensure continuous, high-quality production.

10.1.3.1 *Core process*

The main processes that include the following steps:

a) Providing and assembling moulds, positioning the reinforcement cage for reinforced concrete work and stressing the wires for prestressed elements;

b) Installing concealed service conduits/pipes;

c) Fixing inserts and tubes as necessary (for handling purposes);

d) Pouring concrete into the moulds;

e) Vibrating and finishing the concrete;

f) Curing the concrete; and

g) Demoulding the forms and stacking the precast products.

10.1.3.2 *Auxiliary process*

These processes are necessary for the successful completion of the core processes and include the following:

a) Mixing and producing fresh concrete (carried out in a mixing station or batching plant);

b) Prefabricating the reinforcement cage (performed in a steel yard or workshop);

c) Manufacturing inserts and other finishing components to be incorporated into the main precast products; and

d) Finishing the precast products.

10.1.3.3 *Subsidiary process*

Subsidiary processes shall include material handling, maintenance and utility services essential for uninterrupted production. These shall include:

a) Proper storage of raw materials;

b) Internal transport systems for fresh concrete and cages;

c) Safe movement and stacking of precast elements;

d) Periodic servicing of equipment and moulds; and

e) Maintenance of curing and utility facilities (for example, steam).

10.1.4 The manufacturing of precast elements requires systematic planning of all the processes to achieve the following objectives:

a) A cyclic working method to enhance speed and cost-efficiency in production;

b) Mechanization of processes to boost productivity and improve quality;

c) Optimal production levels that meet quality control standards while maintaining the desired construction speed;

d) Improved working conditions for the workforce; and

e) Minimization of weather-related disruptions to the manufacturing schedule.

10.1.5 The various stages of precasting, as outlined in Table 12, are classified based on the equipment required for each stage. This classification facilitates the mechanization and rationalization of work throughout the process. Stages 6 and 7, as shown in Table 12, represent the core processes in the manufacturing of precast concrete elements. For these stages, various technological processes are employed, tailored to the specific concrete product being produced. These methods have been proven to be rational, economical and time-saving. Figure 40 provides a diagrammatic representation of the different stages involved in the plant process.

10.1.6 The accepted methods of manufacturing precast units can be broadly classified into two categories:

a) The stationary method, where the moulds remain in a fixed position and the various processes are carried out in a cyclic order at the same location; and

b) The circulation method, where the precast unit moves through different stages of production, with the processes being carried out in an assembly-line fashion.

The various accepted pre-casting methods are listed in Table 13 along with the details regarding the elements that can be manufactured by these methods.

Table 12 Stages of Precasting of Concrete Products

(*Clause* 10.1.5)

Sl No. (1)	**Precasting Stage No.** (2)	**Name of Process** (3)	**Operations Involved** (4)
i)	1	Procurement and storage of construction materials	Unloading and transport of cement, coarse and fine aggregates and steel, and storing them in bins, silos or storage sheds
ii)	2	Testing of materials	Testing of all materials including steel
iii)	3	Design of concrete mix	Testing of raw materials, plotting of grading curves and trial of mixes in laboratory
iv)	4	Making of reinforcement cages	Unloading reinforcement bars from wagons or lorries and stacking them in the steel yard, cutting, bending, tying or welding the reinforcements and making in the form of a cage, which can be directly introduced into the mould
v)	5	Applying form release agent and laying of moulds in position	Moulds are cleaned, applied with form release agent, and assembled and placed at the right place
vi)	6	Placing of reinforcement cages, inserts and fixtures	The reinforcement cages are placed in the moulds with spacers, etc, as per data sheet prepared for the specific prefabricate units. Pre-tensioning of wires in the case of pre-stressing of concrete element

Table 12 (*Concluded*)

Sl No. (1)	Precasting Stage No. (2)	Name of Process (3)	Operations Involved (4)
vii)	7	Preparation of green concrete	Taking out aggregates and cement from bins, silos, etc, batching and mixing
viii)	8	Transport of green concrete	Transport of green concrete from the mixer to the moulds. In the case of precast method involving direct transfer of concrete from mixer to the mould or a concrete hopper attached to the mould this prefabrication stage is not necessary
ix)	9	Pouring and consolidation of concrete	Concrete is poured and vibrated to a good finish
x)	10	Curing of concrete and demoulding	Either natural curing with water or an accelerated curing using steam and other techniques. In the case of steam curing using trenches or autoclaves, this stage involves transport of moulds with the green concrete into the trench or autoclave and taking them out after the curing and demoulding elements. Cutting of protruding wires also falls in this stage. In certain cases, the moulds have to be partly removed and inserts have to be removed after the initial set. Final demoulding is done after concrete has gained designed strength, enough to resist handling stress, and the components are then allowed to be cured further. The minimum curing duration is as per Part C/Section 5 of this NBCS except in cases where the design strength of the precast element is achieved earlier. In that case, curing only up to achieving the design strength is sufficient, subject to appropriate approvals
xi)	11	Stacking of precast elements	Lifting of precast elements from the mould and transporting to the stacking yard for further transport by trailer or rail is part of this stage
xii)	12	Testing of finished components	Tests are carried out on the components individually and in combination to ensure the adequacy of their strength
xiii)	13	Miscellaneous	a) Generation of steam involving storing of coal or oil necessary for generation of steam and providing insulated steam pipe connection up to the various lines b) Repair of machines used in the production

FIG. 40 PLANT PROCESS

Table 13 Precasting Methods

(*Clauses* 10.1.6 *and* 10.6.1)

Sl No.	Precasting Method	Where Used	Recommended Dimensions and Weights	Advantages and Remarks
(1)	(2)	(3)	(4)	(5)
i)	*Individual mould method* — Precasting method using mould which may be easily assembled out of bottom and sides, transportable, if necessary. This may be either in timber or in steel using needle or mould vibrators and capable of taking pre-stressing forces	Ribbed slabs, beams, girders, window panels, box type units and special elements, prestressed railway sleepers, parts of pre-stressed girders, etc	No limit in size and weight. It depends on the equipment used for demoulding, transporting and placing	Strengthening of the cross-section possible Openings are possible in two planes
ii)	*Battery mould method* — The shuttering panels may be adjusted into the form of a battery at the required distances equal to the thickness of the concrete member	Interior wall panels, shell elements, reinforced concrete battens, rafters, purlins, roof and floor slabs	Length ≤ 9 m Height ≤ 3 m Mass ≤ 5 t	Especially suitable for mass production of wall panels where shuttering cost largely reduced. Vapour or steam curing may be adopted by taking the steam pipes through the shuttering panels
iii)	*Stack method*	Floor and roof slab panels	Length: Any desired length Breadth: 1 to 4 m Mass ≤ 5 t	For casting identical reinforced or pre-stressed panels one over the other with separating media interposed in between
iv)	*Tilting mould method* — This method is capable of being skipped vertically using hydraulic jacks	Exterior wall panels where special finishes are required on one face or for sandwich panel	Length ≤ 6 m Breadth ≤ 4 m Mass ≤ 5 t	Suitable for manufacturing the external wall panels
v)	*Long line prestressing bed method*	Double tees, ribbed slabs, purlins, piles and beams	Length ≤ Any desired length Breadth ≤ 2 m Height ≤ 2 m Mass : Up to 10 t	Ideally suited for pretension members
vi)	*Extrusion method* — Long concrete mould with constant cross-section where concreting and vibration are done automatically just as in hollow cored slab casting	Roof slabs, foam concrete wall panels and beams cross-section	Length : Any desired length Breadth : < 2 m Height : < 3 m	May be used with advantage in the case of un-reinforced blocks, foam concrete panels

10.1.7 *Preparation and Storage of Materials*

Proper storage of materials is crucial in the precast industry, as errors in planning this aspect can significantly impact production economics. In a precast factory, where quality is paramount, the proper storage and preservation of building materials especially cement, coarse aggregates and fine aggregates are essential. Materials should be stored in accordance with accepted standard [C-7(21)]. Additionally, precast elements should follow a 'first-in, first-out' (FIFO) system to minimize or avoid issues related to shrinkage, creep and other material-related concerns.

10.2 Moulds

10.2.1 Moulds used for the manufacture of precast elements may be made from steel, timber, concrete, plastic, or a combination of these materials. When designing moulds for various elements, special attention should be given to facilitating easy demoulding and the assembly of parts. Additionally, the rigidity, strength, and watertightness of the mould are critical, especially considering the forces involved during the pouring of green concrete and the vibrating process. The deflection of any supporting member of the mould shall not exceed $L/350$ or 3 mm, whichever is less, where L represents the span of the member in millimetres).

10.2.2 Tolerances

The moulds shall be designed to accommodate the tolerances as per the casting tolerances given in Table 14.

Table 14 Casting Tolerances for Precast Components

(*Clause* 10.2.2)

Sl No.	Product (*See* Key No.)	Product Tolerances
(1)	(2)	(3)
i)	*Length*:	
	1, 10, 12, 15, 16, 17	± 5 mm
	9, 11	± 10 mm
	2, 3, 4, 6, 7, 8	± 10 mm
	5	± 2 mm for length below and up to 500 mm ± 5 mm for length over 500 mm
	13, 14, 18, 19	± 15 mm
ii)	*Thickness/cross sectional dimensions*:	
	1	± 3 mm
	2, 8	± 3 mm or 0.1 percent, whichever is greater
	4, 5, 7, 10, 12, 15	± 3 mm, for thickness up to 300 mm ± 5 mm, for thickness greater than 300 mm
	3, 6, 9, 11, 16, 17, 18, 19	± 5 mm
	13, 14	+ 5 mm, - 3 mm
iii)	*Straightness/bow*:	
	2, 4, 5, 7, 8, 10, 15, 16, 18	1/360 of length, maximum of ± 10 mm
	1, 5	± 3 mm
iv)	*Squareness* — When considering the squareness of the corner, the longer of two adjacent sides being checked shall be taken as the base line:	
	a) *Skew across width of an end:*	
	15	± 3 mm per 300 mm length, with maximum of ± 5 mm
	7, 9	± 3 mm per 300 mm length, with maximum of ± 10 mm
	1, 2, 4, 5, 8, 10, 11	± 3 mm per 300 mm length, with maximum of ± 15 mm

Table 14 (*Concluded*)

Sl No.	Product (*See* Key No.)	Product Tolerances
(1)	(2)	(3)
	b) *Skew across thickness or depth or height of an end*:	
	12, 16	± 3 mm
	4, 7, 8, 16	± 3 mm per 300 mm length
	13, 14	Depth ≤ 600 mm, ± 5 mm Depth ≥ 600 mm ± 1.5 mm for 300 mm length with maximum of ± 15 mm
v)	*Twist* — Any corner shall not be more than the tolerance given below from the plane containing the other three corners:	
	2, 8	5 mm, Up to 600 mm in width and up to 6 m in length 10 mm, Over 600 mm in width and for any length
	4	± 1/1 500 of dimension or ± 5 mm, whichever is less
	1	± 3 mm
	7	± 1 mm
vi)	*Flatness* — The maximum deviation from 1.5 m straight edge placed in any position on a nominal plane surface shall not exceed:	
	2, 8	± 5 mm
	4	± 3 mm
	1	± 2 mm
	5	± 5 mm or maximum of 0.1 percent length
vii)	*Warping* — Deviation from plane in which the corners of the panel do not fall within the same plane:	
	2, 4, 5, 7, 8, 16, 18	± 1.5 mm per 300 mm length
	10, 15	± 5 mm

		13	Single tee		

10.2.3 *Mould Wall Slopes*

To facilitate the easy removal of precast elements from the mould, particularly when the mould has fixed sides and the elements need to be lifted out, the side slopes should ideally be 1 in 6 but shall not be less than 1 in 12. For slopes less than 1 in 6, the mould should have provisions of appropriate hydraulic jacks at the base of the mould to assist demoulding. A gentle slope helps prevent the elements from becoming stuck in the mould during demoulding.

10.3 Accelerated Curing

In precasting factories, using accelerated or artificial curing methods is economical, as it allows elements to be demoulded much earlier, enabling the early re-use of moulds. Any of the following methods shall be adopted:

10.3.1 *Steam Curing*

10.3.1.1 The steam curing of concrete products shall take place under tarpaulin in tents, under hoods, under chambers, in tunnels or in special autoclaves. The steam shall have a uniform flow throughout the length of the member. The precast elements shall be so stacked with sufficient clearance between each other and the bounding enclosure, to allow proper circulation of steam.

10.3.1.2 Before the concrete products are subjected to any accelerated method of curing, the cement to be used shall be tested for soundness, setting time and suitability for steam curing.

10.3.1.3 In the case of elements manufactured by accelerated curing methods, concrete admixtures to reduce the water content may be allowed to be used. The normal aeration agents used to increase the workability of concrete should not be allowed to be used. Use of calcium chloride-based admixtures should not be used for reinforced concrete elements so as to meet the chloride limits prescribed in Part C 'Structural design, Section 5 Structural Concrete' of this NBCS.

10.3.1.4 The inside face of the steam curing chamber, tunnel or hood shall have a damp-proof layer to maintain the humidity of steam. Moreover, a proper slope shall be given to the floor and the roof to allow the condensed water to be easily drained away. When steam is first let into the curing chambers, the air inside shall be allowed to go out through openings provided in the hoods or side walls which shall be closed soon after moist steam is seen jetting out.

10.3.1.5 It is preferable to let in steam from the top of the chamber through perforated pipelines to allow uniform entry of steam throughout the chamber.

10.3.1.6 The fresh concrete in the moulds should be allowed to get the initial set before allowing the concrete to come into contact with steam. The regular heating up of fresh concrete products from about 20 °C to 35 °C should start only after a waiting period ranging from 2 h to 5 h depending on the setting time of cement used. It may be further noted that steam can be let in earlier than this waiting period, provided the temperature of the concrete product does not rise beyond 35 °C within this waiting period.

10.3.1.7 The second stage in steam curing process is to heat up the concrete elements, moulds and the surroundings in the chamber in the following manners:

a) In the low-pressure steam curing, the airspace around the member is heated up to a temperature of 75 °C to 80 °C at a gradual rate, usually not faster than 30 °C/h (this process takes around 1 h to 1 h 30 min depending upon outside temperature); and

b) In the case of curing under high pressure steam in autoclaves, the temperature and pressure are gradually built up during a period of about 4 h.

10.3.1.8 The third stage of steam curing is to maintain the uniform temperature and pressure for a duration depending upon thickness of the section. This may vary from 3 h to 5½ h in the case of low-pressure steam curing and 4 h to 7 h in the case of high-pressure steam curing.

10.3.1.9 The fourth stage of steam curing is the gradual cooling down of concrete products and surroundings in the chamber and normalization of the pressure to bring it at par with outside air. The maximum cooling rate, which is dependent on the thickness of the member, should normally not exceed 30 °C/h.

10.3.1.10 In all these cases, the difference between the temperature of the concrete product and the outside temperature should not be more than 60 °C for concrete up to M30 and 75 °C for concretes of M45 or greater. In the case of light weight concrete, the difference in temperature should not be more than 60 °C for concretes less than M25. For concretes greater than M50, the temperature differences can go up to 75 °C.

10.3.2 *Vapour Curing*

Vapour curing shall consist of maintaining a high relative humidity around the concrete by means of application of moisture in the form of vapour or steam. The system and requirements shall be similar to those specified under 10.3.1. The temperature range to be maintained shall be as recommended by the manufacturer of the equipment, depending upon the product requirements.

10.3.3 *Steam Injection during Mixing of Concrete*

Low pressure saturated steam shall be injected into the mixer during the mixing of aggregates. This process shall raise the temperature of the concrete to about 60 °C. Concrete so produced, when placed in the moulds, shall develop high early strength.

10.3.4 *Heated Air Method*

The concrete elements are kept in contact with hot air with a relative humidity not less than 80 percent. This method is particularly suitable for light weight concrete products using porous coarse aggregates.

10.3.5 *Hot Water Method*

The concrete elements shall be immersed in a bath of hot water maintained at a temperature between 50 °C and 80 °C. The principles of this method shall generally be similar to those of steam curing.

10.3.6 CO_2 *Curing*

Carbon dioxide shall be injected into the concrete during mixing. This promotes faster hydration and is particularly effective in accelerating the hardening of precast concrete elements, thereby improving both efficiency and quality.

10.3.7 Concrete elements subjected to any of the accelerated curing methods specified in **10.3.2** to **10.3.6** shall be subjected thereafter to normal curing methods, so as to enable the development of the final strength.

10.3.8 *Other Methods of Accelerated Hardening*

Accelerated hardening of concrete may also be achieved by one or more of the following techniques:

a) *Use of Construction Chemicals* — Suitable construction chemicals may be used for promoting early hardening;

b) *Consolidation by Spinning* — This method shall generally be employed in centrifugal moulding of pipes and similar units. The spinning action removes excess water, effects consolidation, and permits earlier demoulding;

c) *Pressed Concrete* — This method shall be suitable for the fabrication of small or large products at high rates of production. Presses in the range of 100 t to 200 t capacity shall be used to compress the wet concrete in rigid moulds, thereby expelling excess water. This results in early handling and produces dense, wear-resistant concrete;

d) *Vacuum Treatment* — In this method, surplus air and water shall be removed from the freshly placed concrete (for example, slabs and similar elements). A suction of up to 70 percent of an atmosphere shall be applied for a period of 20 min to 30 min per cm thickness of the units; and

e) *Consolidation by Shock* — This method shall be suitable for small concrete units placed in strong moulds and subjected to repeated dropping from a height. The number of shocks required to expel excess water and air may vary from 6 to 20 and the height of drop may be up to half the depth of the mould.

10.3.9 *Stacking During Transport and Storage*

Every precaution shall be taken against overstress or damage, by the provision of suitable packing at agreed points of support. In general, the final condition of the elements in the structure should be studied to finalize on the staking support. Even number of supports is preferred over the odd number of supports. Particular attention is directed to the inherent dangers of breakage and damage caused by supporting other than at two positions, and by the careless placing of packing (for example, not vertically one above the other). Ribs, corners and intricate projections from solid section should be adequately protected. Packing pieces shall not stain, disfigure or otherwise cause permanent mark on units or members. Stacking shall be arranged, or the precast units protected, to prevent the accumulation of trapped water or rubbish and, if necessary, to reduce the risk of efflorescence.

The following points shall be kept in view during stacking:

a) Care should be taken to ensure that the flat elements are stacked as per their final position at the structure. For identification, top surfaces should be clearly marked;

b) Stacking should be done on hard and suitable ground to avoid any sinking of support when elements are stacked;

c) In case of horizontal stacking, packing materials shall be at specified locations and shall be exactly one over the other to avoid cantilever stress in panels;

d) Components should be packed in a uniform way to avoid any undue projection of elements in the stack which normally is a source of accident;

e) In general, vertical stacking should be limited to 6 components to 10 components. Minimum ground capacity shall be 5 t/m^2 for stacking of panels. Where the ground is only compacted, the maximum ground load at support should be restricted to 15 t/m^2. Where the ground is of PCC layer, the maximum ground load at support should be restricted to 30 t/m^2 subjected to capacity of the ground. In both cases, the ground should be levelled, and the support should be continuous along the width of the panels; and

f) All wall panels shall be stacked, preferably symmetrically on both sides, against steel A-frames. The slope of the sides of the A-frame shall be between 75° and 80° to the horizontal and the bottom of the frame shall be provided with concrete footings to resist component of self- weight and horizontal wind pressure on the wall panel. A similar type of A-frame should be used for transporting wall panels.

10.4 Handling Arrangements

10.4.1 Lifting and handling positions shall be clearly defined particularly where these sections are critical. Where necessary special facilities, such as bolt holes or projecting loops, shall be provided in the units and full instructions supplied for handling. For bolts/hooks, bond strength shall be the criteria for embedded bolts and bearing strength for through bolts. For bond strength, pull out test of concrete shall be carried out. *See* **10.8** for additional design considerations.

10.4.2 For precast pre-stressed concrete members, the residual pre-stress at the age of operation of handling and erection shall be considered in conjunction with any stresses caused by the handling or erection of member. The compressive stress thus computed shall not exceed 50 percent of the cube strength of the concrete at the time of handling and erection. Tensile stresses up to a limit of 50 percent above those specified in Part C/Section 5 of this NBCS shall be permissible.

10.5 Identification and Marking

All precast units shall bear an indelible identification, location and orientation marks as and where necessary. The date of manufacture shall also be marked on the units.

The identification markings on the drawings shall be the same as that indicated in the manufacturer's literature and shall be shown in a tabular format on the setting schedule together with the length, type, size of the unit, and the sizes and arrangement of all reinforcement. Implementation of QR Code or similar stickers pasted on precast elements with above mentioned details are highly recommended.

10.6 Transport

Transport of precast elements inside the factory and to the site of erection is of considerable importance not only from the point of view of economics but also from the point of view of design and efficient management. Transport of precast elements shall be carried out with extreme care to avoid any impact and distress in elements and handled as far as possible in the same orientation as it is to be placed in the final position. *See* **10.8** for additional design considerations.

10.6.1 *Transport Inside the Factory*

Transport of precast elements moulded inside the factory depends on the method of production selected for the manufacture as given in Table 13.

10.6.2 *Transport from Stacking Yard Inside the Factory to the Site of Erection*

10.6.2.1 Transport of precast concrete elements from the factory to the site of erection should be planned in such a way to be in conformity with the traffic rules and regulations as stipulated by the Authorities. The size of the elements is often restricted by the availability of suitable transport equipment, such as tractor-cum-trailers, to suit the load and dimensions of the member in addition to the opening dimensions under the bridge and load carrying capacity while transporting the elements over the bridge.

10.6.2.2 While transporting elements in various systems, that is, wagons, trailers, trucks, etc, care should be taken to avoid excessive cantilever actions and desired support are maintained. Transportation of prefabricated elements should be carried out with care. Sufficient care should be taken to also protect the steel inserts and reinforced bars of the precast elements during transportation. Precast elements should be secured with safety ties to ensure that vibrations to the elements in transit are minimum. Special care should be taken at location of sharp bends and on uneven or slushy roads to avoid undesirable stresses in elements.

10.6.2.3 Before loading the elements, care should be taken to ensure that the base packing for supporting the elements is located at specified positions only. Subsequent packing shall be kept strictly one over the other.

10.7 Erection

10.7.1 Tower cranes or other mobile cranes have varying lifting capacities at different radii, with the maximum weight at a radius closer to the centre and the minimum weight at a radius farther from the centre. To minimize the number of precast elements, the selected crane should be capable of handling the heaviest precast elements at its maximum radius. The floor plan should indicate the weight of panels at different crane radii, ensuring they align with the crane's lifting capacity at each radius.

In the erection of precast elements, all the following items of work are meant to be included:

a) Slinging of the precast element;

b) Tying up of erection ropes connecting to the erection hooks;

c) Cleaning of the elements and the site of erection;

d) Cleaning of the steel inserts before incorporation in the joints, lifting of the elements, setting them down into the correct envisaged position;

e) Adjustment to get the stipulated level, line and plumb by means of levelling bolts and adjustable props;

f) Welding of cleats;

g) Changing of the erection tackles;

h) Putting up and removing the necessary scaffolding or supports;

j) Welding of the inserts, laying of reinforcements in joints and grouting the joints; and

k) Finishing the joints to bring the whole work to be like finished product.

See **10.8** for additional design considerations.

10.7.2 Since the erection work in various construction jobs using prefabricated concrete elements differs from place to place depending on the site conditions, safety precautions in the work are of utmost importance. Hence, only those skilled foremen, trained workers and fitters who have been properly instructed about the safety precautions to be taken should be employed on the job.

10.7.3 Transport of people, workers or visitors, by using cranes shall be strictly prohibited on an erection site.

10.7.4 *For Travelling Cranes*

a) The travel tracks shall be perfectly levelled both longitudinally and transversally;

b) The gauge shall be constant and the rail tracks perfectly straight and with the same shape along the entire path;

c) The rail tracks shall be placed on a solid base;

d) Travelling stop buffers shall be placed at the ends of the rail tracks;

e) For rail shape tolerances, the OEM’s installation manual shall be referred; and

f) The track of the crane should be checked daily to see that all fish plates and bolts connecting them to the sleepers are in place and in good condition.

10.7.5 The operation of all equipment used for handling and erection shall follow the operations manual provided by the manufacturer. All safety precautions shall be taken in the operations of handling and erection.

10.7.6 *Erection Tolerances*

As per Table 15.

Table 15 Erection Tolerance for Precast Components

(*Clause* 10.7.6)

Sl No. (1)	Product (2)	Tolerances mm (3)
i)	Level differences between support lines of floor or wall panels	± 5
ii)	Plumb lines of wall panels	± 5
iii)	Bearing for precast floor panels	± 5
iv)	Joint dimensions	± 5
v)	Maximum accumulated deviation	
	a) Till 10 storey building	1/1 250 of height or length or ± 20
	b) Greater than 20 storey building	1/1 250 of height or length or ± 50 (whichever is lesser)
vi)	Variation in plan location (any column or beam, any location)	± 10 for column ± 15 for beams
vii)	Variation in plan parallel to specified building lines	+ 2 mm per meter for any beam less than 6 m long or adjacent to columns paced 6 m apart or less 15 mm maximum for adjacent columns spaced more than 6 m

10.8 Design Considerations

Based on the design intent, production environment and aesthetic requirements of the prefabricated panels, the resultant stresses should be controlled to minimize cracking in precast and/or prestressed panels. Precast (non-prestressed) components are generally designed as ‘cracked’ unless cracking is an aesthetic concern. However, demoulding of precast elements shall not be allowed until the concrete achieves a strength of at least 1.25 times the (extreme fibre) stress which the concrete may be subjected at the time of demoulding. The same shall be applicable while transporting and erection. Reference may be made to Table 7 for load multiplier to ascertain handling stress. The strength referred to shall be that of concrete using the same cement and aggregates and admixture, if any, with the same proportions and cured under conditions of temperature and moisture similar to those existing on the work.

10.8.1 Structural design requirements of minimum spacing, skin reinforcement and crack width criteria as specified in Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS should be applicable.

10.8.2 Lifting hooks should be located such that while lifting the panel, minimum bending moments are produced.

10.8.3 Static load multipliers should be used to account for impact, and demoulding forces as per Table 7.

10.8.4 The load multipliers are only needed for the flexural design and are not applicable for the lifting devices. Lifting hooks shall be designed as per **7.14.6**.

10.8.4.1 For wall panels cast vertically on tilting moulds, battery moulds, and other vertically cast elements, the required concrete strength is not always dictated by flexural stresses. Instead, the minimum concrete strength during the initial lift may be governed by the capacity requirements of the lifting inserts. The capacity of the lifting inserts may be lower than their rated value due to factors such as inadequate embedment depth, insufficient edge distances, or low concrete strength at the time of lifting. Therefore, higher concrete strengths than those recommended in Table 9 may be necessary to fully develop the capacity of certain lifting inserts and ensure the safe handling of the panels.

10.8.4.2 For prestressed elements, special care must be taken to ensure that lifting devices are anchored in compression zones, unless otherwise specified by the design.

10.8.4.3 Initial lifting should be done cautiously and gradually to overcome suction and friction, avoiding the application of sudden impact forces.

10.9 Equipment

10.9.1 The strategic equipment used in the precast concrete industry/construction may be classified into the following categories:

a) *Production equipment* — Batching plant, concrete shuttle conveyors concrete vibrators, circulation tables, EOT, gantry, shear lines, stirrup making machines, weld mesh machines, robots;

b) *Erection equipment* — Tower cranes, Mobile cranes, derricks, hoists, chain pulley blocks, etc;

c) *Transport machinery* — Tractor-*cum*-trailers, dumpers, lorries, locomotives and rarely even helicopters;

d) *Workshop machinery* — For making and repairing steel and timber moulds;

e) Minor tools and tackles, such as lifting equipment, electric vehicle-dumpers, concrete buckets, etc; and

f) Steam generation plant for accelerated curing.

Each of the above groups may further be classified into various categories of machines and further to various other types depending on the source of power and capacity. For use of renewable energy sources to achieve sustainability in precast construction **G-3** shall be referred.

10.9.2 *Mechanization of the Construction and Erection Processes*

The processes can be mechanized/automated, similar to other industries, to achieve the benefits of mass production of standardized components. This approach will enhance productivity, lower production costs over time and ensure consistent product quality.

10.10 Systems for Mixed and Composite Construction

The system of mixed and composite construction depends on the extent of the use of prefabricated components, their materials, sizes and the technique adopted for their manufacture and use in building.

10.10.1 *Combinations of System Components for Mixed and Composite Construction*

The following combinations may be used in mixed and composite construction:

a) Structural steel work and timber roofs on precast frames;

b) Precast half slab, solid slabs, hollow core slabs (floors) onto steel and concrete beams and masonry walls;

c) Profiled metal decking on precast beams;

d) Cast in situ slab on precast wall;

e) Precast slab on cast in situ wall/3D printed wall;

f) Precast frames onto cast in-situ foundations, retaining walls, etc;

g) Precast frames stabilized by masonry walls, steel bracing, etc;

h) Precast cladding in steel or cast in-situ frames and vice-versa;

j) Glass curtain walling, stone cladding or metal sheeting onto precast concrete frames, etc; and

k) Reinforced concrete and structural steel as composite columns and beams.

10.10.2 Precast concrete may be combined with cast in-situ concrete, often termed hybrid construction. Cast in-situ is mostly used to form homogenous connections between precast elements and provide a structural topping for horizontal diaphragm action. In other cases, it is used to form the foundations and sub-structure to the building.

10.10.3 Structural steel work is largely used in long span prestressed concrete floors (hollow core) supported on rolled and prefabricated steel beams and also as steel roof trusses supported on concrete columns.

10.10.4 Timber may be used as long span glue-laminated beams and rafters, with precast concrete. Precast floors may be used in timber frame construction. Similarly, timber frames with precast elements shall be used as a building system.

10.10.5 Brick and block masonry may be combined with precast concrete structures and floors. The most common combination is to use prestressed floors on load bearing walls.

NOTE — Any prefabricated floor system covered under other Indian Standards, for example, reinforced concrete plank system and speed floor system may be combined with load bearing masonry walls/insulating concrete form (ICF) walls/precast large reinforced concrete wall panels/precast or cast in-situ reinforced concrete column-beam frames provided overall structural design safety, stability and integrity for composite structure is ensured in accordance with this section and other safety standards, such as good practice [C-7(1)], **5** of Part C/Section 1 of this NBCS including fire safety and safety against progressive collapse as per provisions of respective good practices, such as [C-7(19)], Part C/Section 5 and Part C/Section 6A of this NBCS.

10.10.6 *Design Considerations*

The mixed and composite structures shall be analysed appropriately and the joints in them designed to take the forces of an equivalent discrete system. Resistance to horizontal loading shall be provided by placing beams, walls and/or bracings in two directions at right angles or otherwise. The individual components shall be designed, taking into consideration appropriate end conditions and loads at various stages of construction. The components of the structure shall be designed for loads in accordance with good practices [C-7(1)] and[C-7(20)] and **5** of Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS. In addition, members shall be designed for handling, erection and impact loads that may be expected during handling and erection.

For mixed and composite construction, the following shall be considered:

a) *Positions of stability cores, walls, bracing, etc* — In high rise buildings, the most popular method is a central core constructed several storeys ahead of the framework. The core could be built using either precast concrete panels, or cast in-situ walls, or steel cross bracing or precast concrete diagonal bracing;

b) *Maturity of connections* — Cast-in-situ grouted joints need temporary propping until desired design strength is achieved unless combined mechanical connections are also used. The overall construction sequence should be planned ahead of time carefully as per the design requirements. The design of temporary bracing system using key components should be looked at critically;

c) *Availability and/or positioning of equipment to transport and erect components* — The size and weight of the various components shall be organized to make optimum use of crane capacity, for example, the lightest units farthest from the operating zone;

d) *Erection safety and speed of construction, with attention to cast in-situ concreting sequences* — This is particularly important where fixing gangs are unaccustomed to working with different materials; and

e) *Tolerances for construction* — This is particularly important where different manufacturers are producing components in different materials.

Other design considerations and safety requirements against progressive collapse shall be in accordance with this NBCS.

10.11 Prefabricated Structural Units

For the design and construction of composite structures made up of prefabricated structural units and cast in-situ concrete, reference may be made to good practice [C-7(22)].

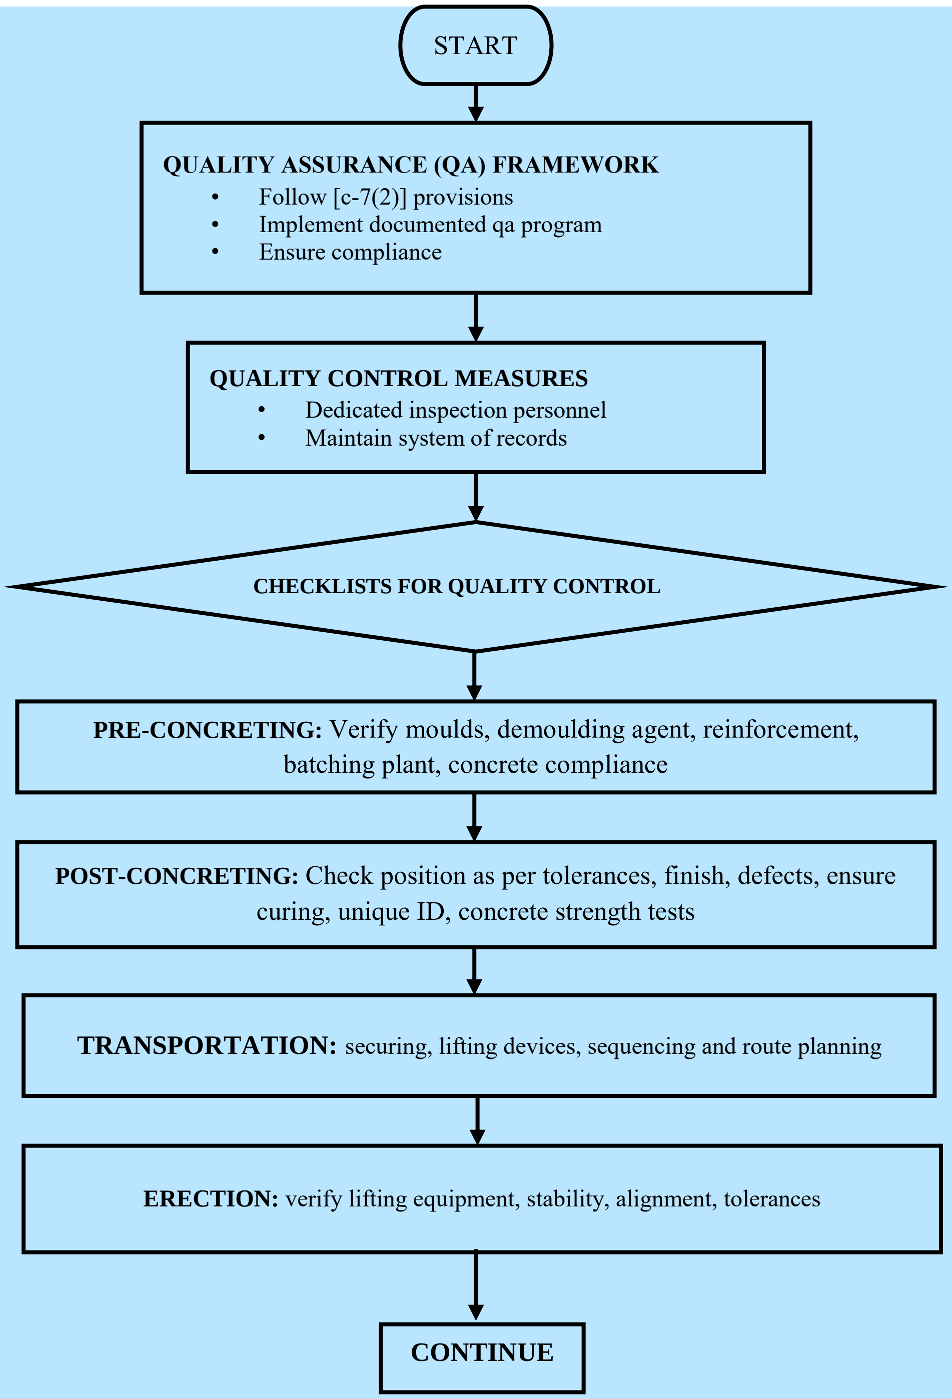
For design and construction of precast reinforced and prestressed concrete triangulated trusses, reference may be made to good practice [C-7(23)].

For design and construction of floors and roofs using various precast units, reference may be made to good practice [C-7(24)].

For construction of floors and roofs with joists and filler blocks, reference may be made to good practice [C-7(25)].

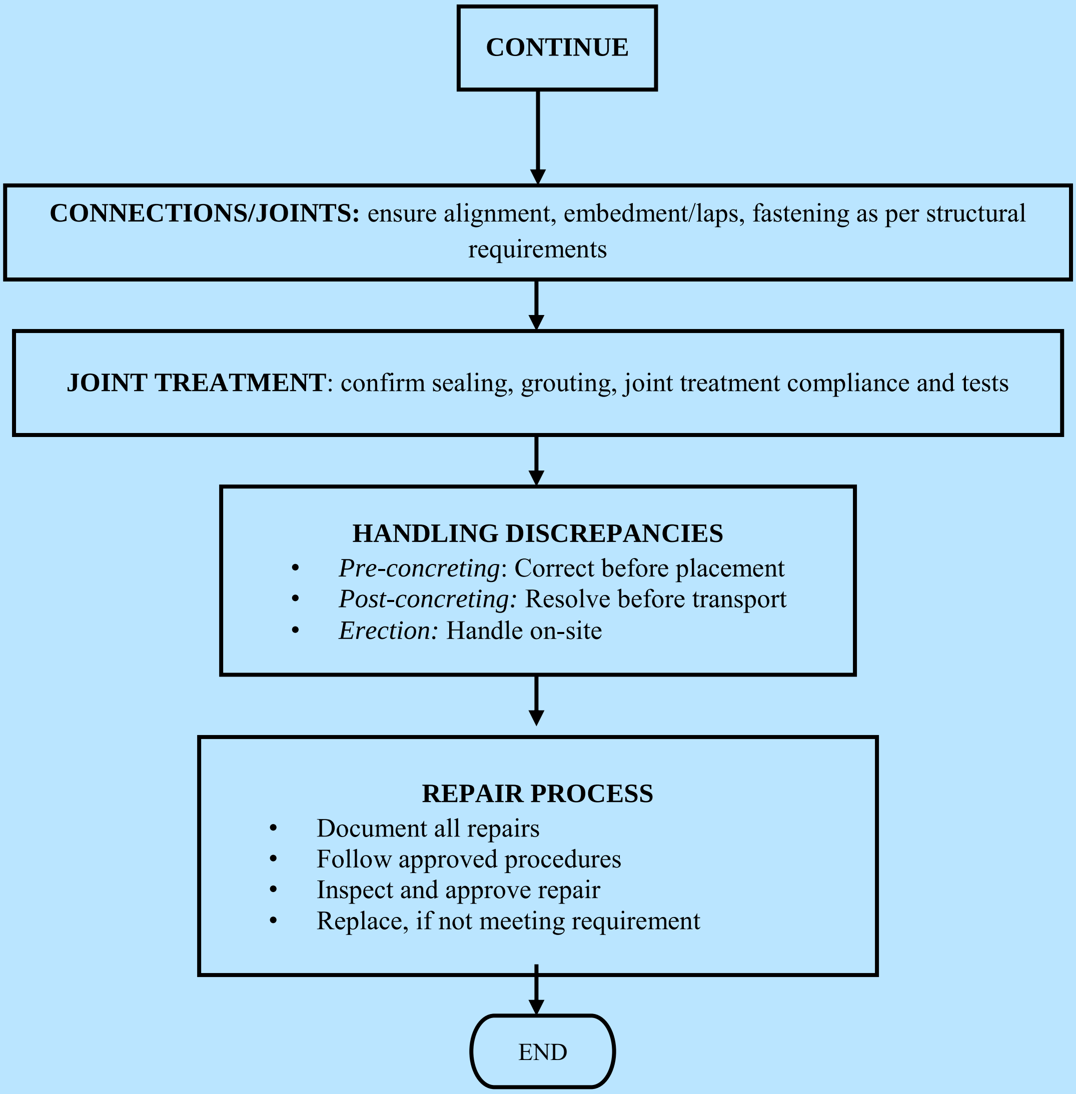
11 QUALITY ASSURANCE AND QUALITY CONTROL

The provisions for quality assurance as per good practice Part C/Section 5 of this NBCS shall apply. A documented quality assurance program covering various stages from precast unit/element production to erection shall be implemented and maintained. Common defects and remedies in precast concrete elements are presented in Annex F. For achieving sustainability in precast concrete construction a reference may be made to Annex G. Additionally, the flow chart given in Fig. 41 shall be considered.



START
QUALITY ASSURANCE (QA) FRAMEWORK
Follow [c-7(2)] provisions
Implement documented qa program
Ensure compliance
QUALITY CONTROL MEASURES
Dedicated inspection personnel
Maintain system of records
CHECKLISTS FOR QUALITY CONTROL
PRE-CONCRETING: Verify moulds, demoulding agent, reinforcement, batching plant, concrete compliance
POST-CONCRETING: Check position as per tolerances, finish, defects, ensure curing, unique ID, concrete strength tests
TRANSPORTATION: securing, lifting devices, sequencing and route planning
ERECTION: verify lifting equipment, stability, alignment, tolerances
CONTINUE

FIG. 41 FLOWCHART FOR QUALITY ASSURANCE AND CONTROL (CONTINUED)



CONTINUE
CONNECTIONS/JOINTS: ensure alignment, embedment/laps, fastening as per structural requirements
JOINT TREATMENT: confirm sealing, grouting, joint treatment compliance and tests
HANDLING DISCREPANCIES
• Pre-concreting: Correct before placement
• Post-concreting: Resolve before transport
• Erection: Handle on-site
REPAIR PROCESS
• Document all repairs
• Follow approved procedures
• Inspect and approve repair
• Replace, if not meeting requirement
END

FIG. 41 FLOWCHART FOR QUALITY ASSURANCE AND CONTROL

12 TESTING

12.1 Sampling procedures

12.1.1 *Lot*

12.1.1.1 All the precast units of same size, manufactured from same material under similar conditions of production shall be grouped together to constitute a lot.

12.1.1.2 The number of units to be selected from each lot for dimensional requirements shall depend upon the size of the lot and shall be in accordance with col (3) and col (4) of Table 16.

12.1.1.3 The units shall be selected from the lot at random. In order to ensure the randomness of the selection, reference may be made to accepted standard [C-7(26)].

Table 16 Sample Size and Rejection Number

(*Clauses* 12.1.1.2 *and* 12.1.2.1)

Sl No. (1)	Lot Size (2)	First Sample Size (3)	Second Sample Size (4)	First Rejection Number (5)	Second Rejection Number (6)
i)	Up to 100	5	5	2	2
ii)	101 to 300	8	8	2	2
iii)	301 to 500	13	13	2	2
iv)	501 and above	20	20	3	4

12.1.2 *Number of Tests and Criteria for Conformity*

12.1.2.1 All the units selected at random in accordance with Table 16 shall be subjected to testing of dimensional tolerance requirements. A unit failing to satisfy any of the dimensional requirements shall be termed defective. The following shall be considered:

a) If no defect is found in the sample, the lot shall be considered as conforming else shall be rejected, if the number of defectives is greater than or equal to the first rejection number;

b) If the number of defectives is less than the first rejection number, the second lot shall be subjected to testing for dimensional tolerance requirements; and

c) If the combined number of defectives is less than the second rejection number, the lot shall be considered as conforming to dimensional tolerance requirements; otherwise not.

12.1.2.2 The lot which has been found satisfactory with respect to dimensional tolerance requirements shall then be considered for load testing as per **12.4**. One unit out of every 300 units or part thereof shall be selected for testing. The lot shall be considered as conforming to the strength requirement, if all units meet the requirement; otherwise not.

12.2 Testing on Individual Precast Units

12.2.1 The flexural components shall be load tested individually or along with the structural topping, depending on the requirements of the project or if any structural cracks (as per Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS) or damages are observed. The testing shall be carried out on the selected sample along with one undamaged unit or part for reference. If individual element is tested, then the loads to be placed should be prorated such that element experiences similar demand over capacity levels when loaded. In either case, the element should be loaded for 24 h at its full span with a total load of 1.25 times the sum of dead (including SIDL, etc) and imposed loads used in the design. At the end of this time, it should not show obvious signs of deterioration or excessive deflection. For large span elements, larger than 10 m span, with design stresses near cracking under the ultimate loads, it is not uncommon to see hairline cracks during the load test at maximum loads in sustained conditions. Except for the design criteria of un-cracked elements, if applicable, if the test elements in such cases perform at a satisfactory level with recovery as noted in **12.2.2** and **12.2.3** as applicable, the test should be considered passed. If such cracks are substantial, the test should be further evaluated by the engineer-in-charge.

12.2.2 The recovery of maximum deflection observed during testing after 24 h should not be less than 75 percent.

12.2.3 If prestressed, it should not show any visible cracks up to the working load, and the recovery of maximum deflection observed during testing after 3 h should not be less than 85 percent.

12.2.4 For inspection and testing of the compression members, provision of Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS shall apply.

12.3 Testing of Connecting Devices and Inserts

12.3.1 Grouted coupler or mechanical coupler shall be tested according to accepted standard [C-7(9)]. Where the grouted couplers are used for connections of lateral force resisting system (LFRS) transferring seismic and wind lateral loads, the grouted couplers should also be tested for the reverse cyclic load as per Table 17, in an NABL accredited laboratory or institute of repute under the supervision of appropriate authority.

Table 17 Cyclic Tension and Compression Test for Grouted Coupler

(*Clause* 12.3.1)

Sl No. (1)	Stage (2)	Tension (3)	Compression (4)	Cycles (5)
i)	I	0.95 f_y	0.5 f_y	20
ii)	II	$2\varepsilon_y$	0.5 f_y	4
iii)	III	$5\varepsilon_y$	0.5 f_y	4
iv)	IV	Load in tension till failure		

where

f_y = specified yield strength of the reinforcing bar; and

ε_y = strain of reinforcing bar at actual yield stress.

12.3.2 Any new connection assemblies such as, but not limited to, column shoe or shear connectors, that are used in connection of LFRS as noted in **12.3.1**, shall be tested for monotonic as well as reverse cyclic load as per **12.3.1** in an NABL accredited laboratory or institutes of repute under the supervision of appropriate authority. The failure should only occur in the reinforcement with evidence of ductility without any damage or deterioration in the brittle components of the connection assembly.

12.3.3 Lifting inserts and devices shall be tested for pull-out and should not show any damage till design load (factor of safety times the working load). Factor of safety shall be according to **7.14**.

12.4 Floor Load Testing of Structure or Part of Structure

12.4.1 Floor load testing on a part or entire floor shall be carried out before occupancy, depending on the requirements of the project or if any structural cracks or damages are observed or to ensure adequacy of strength or serviceability.

12.4.2 The structure should be loaded for 24 h with the full dead load and an imposed load equal to 1.25 times the specified imposed load used in design. The imposed load shall be removed, and the deflection shall be monitored. During the test, vertical struts should be placed appropriately to ensure safety.

NOTE — Dead load includes the self-weight of structural members plus weight of finishes and walls or partitions, if any, as considered in the design.

12.4.3 The recovery of maximum deflection shall be at least 75 percent otherwise the test shall be repeated after 72 h. If the recovery after second test is less than 80 percent the structure shall be deemed to be unacceptable. If unacceptable, the strengthening of this structure shall be carried out and 80 percent recovery of the structure shall be verified. The strengthening of the structure shall be verified by relevant authority.

12.4.4 If prestressed, the recovery of maximum deflection should be at least 85 percent, otherwise test shall be repeated after 72 h. If the recovery after second test is less than 85 percent the structure shall be deemed to be unacceptable.

12.4.5 If the maximum deflection in mm, shown during 24 h under load is less than 40 L^2/D, where L is the effective span in m; and D is the overall depth of the section in mm, it is not necessary for the recovery to be measured and the recovery provisions of 12.4.3 and 12.4.4 shall not apply.

12.4.6 *Testing of Connection/Joint and System*

12.4.6.1 Testing of connection or system shall be performed for proprietary or unique connection or system.

12.4.6.2 Monotonic test shall be carried out for beam-column, walls-slab, wall-wall joints for quantifying the static behaviour.

12.4.6.3 Reverse cyclical load simulation test under intended loads of beam-column, wall-slab, wall-wall joints, shall be carried out for quantifying the energy dissipation and hysteresis behaviour.

12.4.6.4 System level testing shall be carried, if required by the contract or specification of the project.

12.4.6.5 Testing shall be carried out in reputed institutes with appropriate requirements.

12.4.6.6 Acceptance criteria for such test should be mutually established by the authority and the concerned institute where testing is being conducted.

12.5 Testing for Water Tightness

12.5.1 *External Precast Wall/Facade Panels*

Any of the testing procedures given in 12.5.1.1 and 12.5.1.2 may be followed for testing of external wall and facade panel joints for water tightness as per the engineer-in-charge.

12.5.1.1 *Testing procedure* 1

12.5.1.1.1 *General*

If it is deemed necessary to demonstrate that the precast facade joints are adequate to resist water penetration, a water penetration test on a full-scale panel including joint mock-ups may be undertaken.

12.5.1.1.2 *Test procedures*

Mock-up panels to be tested for water tightness should be subjected to both static and cyclic pressure in accordance with standard accepted procedures. Available international testing procedures are to be modified for local conditions as follows:

a) Differential test pressure shall be 20 percent of the maximum inward design wind load but not less than 0.77 kPa; and

b) The test shall be performed with a water flow rate of 3.4 litre/min/m^2 for 15 min.

12.5.1.1.3 *Sampling for a water penetration test*

Water tightness testing of vertical and horizontal joints in precast facade panels shall be carried out at the rate of 0.5 percent for each type of joint and combination of panels or at least one for each joint type and precast unit, whichever is greater.

12.5.1.1.4 *Failure criterion*

The facade units or joints are deemed to have failed, if signs of water seepage through the joints or through the facade unit, including signs of damp patches, are observed during the test or within the subsequent 2 h after the test.

12.5.1.1.5 *Remedial action on failure*

Upon failure of a water penetration test on a precast facade system the cause of failure should be identified and the system revised and re-tested until a satisfactory test result is achieved. Modifications shall be realistic in terms of job conditions and shall maintain standards of quality and durability.

12.5.1.2 *Testing procedure* 2

12.5.1.2.1 For external walls, a continuous jet of water shall be sprayed on the joint corresponding to 600 litre/h from a water hose having a nozzle velocity of 2 m/s and a cone scatter of approximately 60° held at a distance of 1.2 m from the wall surface under test. The duration of the test shall not be less than 2 h. The hose shall be placed centred on the horizontal or vertical joint width. For external walls, the following tests shall be conducted for each building block as per Table 18.

Table 18 Frequency of Tests for Vertical and Horizontal Joints

(*Clause* 12.5.1.2.1)

Sl No. (1)	**Building Height** (2)	**Frequency of Tests** (3)
i)	Up to 10 storeys	5
ii)	Up to 20 storeys	10
iii)	Up to 30 storeys	15
iv)	Up to 40 storeys	20
v)	Up to 50 storeys	25

12.5.1.2.2 Twenty percent of these tests shall be carried out at the intersection of the vertical and horizontal joint.

12.5.1.2.3 These tests shall be carried out at any location as instructed by the engineer-in-charge.

12.5.1.2.4 *Acceptance criterion*

Water shall not seep into any part of the building during the test.

12.5.1.2.5 *Remedial action on failure*

For each test that fails, the tested joint shall be repaired as per the approved repair procedure as directed by the engineer-in-charge and the joint shall be retested for performance as per acceptance criterion. Two additional joints should be tested for each failed joint unless directed otherwise by the engineer-in-charge.

12.5.2 *Floor or Roof Slabs, Toilet Units and Kitchen Units*

12.5.2.1 A total of 5 percent of all horizontal floor slabs and the entire roof slab area, including bathroom/toilet floors, and kitchen floors shall be tested for water tightness by ponding of water for period of 4 h. This test shall be carried out before the application of floor finish or tiling. The depth of ponded water shall be taken as the maximum of the following:

a) At least 25 mm; and

b) 10 mm more than thickness of joint.

12.5.2.2 *Acceptance criteria*

Water shall not seep into any part of the building during the test and after 24 h. The rooms below the tested room shall not show any water leakage. Minor dampness or seepage without dripping water in limited area of less than approximately 50 cm^2 is considered acceptable at a few areas and should be repaired suitably to avoid seepage. In any other cases, the test should be repeated per **12.5.2.3**.

12.5.2.3 *Remedial action on failure*

For each test which fails, the tested joint shall be repaired as per the approved repair procedure as directed by engineer-in-charge and the joint shall be retested for water tightness. Two additional joints/areas should be tested for each failed joint unless directed otherwise by the engineer-in-charge.

ANNEX A

(*Clause* 4)

SYMBOLS AND NOTATIONS

A_n	Area of tension reinforcement
A_vf	Area of shear friction reinforcement
A_1	Loaded area (bearing constant area)
A_2	Area of the lower base of pyramid, cone or tapered wedge
b_t	Bearing width
b_w	Average width of the stem for the full depth of the section
d_e	Distance from centre of load to the end of the ledge
f_ck	Characteristic strength of concrete
f_y	Yield strength of tension reinforcement
f_ys	Yield strength of shear reinforcement
h_l	Height of beam ledge
L	Anchorage length
l_p	Length of ledge projection
N_u	Factored axial force
s	Minimum spacing of concentrated loads
V_u	Factored shear force
V_uR	Design shear resistance
β	coefficient dependent on the bar type
τ_b	Bond stress
τ_{bu}	Design ultimate anchorage bond stress
φ_E	Effective bar size which, for a single bar is equal to the bar size and, for a group of bars

ANNEX B

(*Foreword*, *Clauses* 6.5.1 *and* G-6.2.2)

GUIDELINE FOR 3D PRINTED CONCRETE STRUCTURES

B-1 GENERAL

This annex provides an overview of the materials, methods and tests associated with concrete construction using 3D printing for various applications. The provisions contained herein are based on the current state of knowledge and practice in 3D printed concrete construction. In addition to these guidelines, reference shall be made to the applicable existing Indian standards and relevant research publications. Ongoing research at the national and international levels is expected to generate design-related data, which may subsequently be utilized for the purpose of standardization.

B-2 METHODOLOGY AND SCOPE

The following points are considered while defining the application and performance guidelines:

a) *Printing technique* — This document considers only extrusion-based 3D printing technology, where layers are deposited one over the other to construct a structure;

b) *Design freedom* — 3D printing allows for flexibility in the geometry and form. The shape, size and topology of any 3D printed concrete element for any application shall not be restricted. However, the performance requirements for 3D printing need to be satisfied;

c) *Material* — The material shall be printable and buildable. As per the current state of knowledge of concrete for 3D printing, the limits on the usage of cementitious materials as given in good practice [C-7(6)] and Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS would not be applicable for 3D printed concrete. The assessment of 3D printability of any concrete mixture needs to be carried out as per the available specialist literature on the subject. The mechanical, durability and long-term properties of the printable material shall be determined, as applicable. In the absence of a well-established procedure for preparation of test specimens for such evaluations, reference shall be made to recognized specialized literature. The testing shall be conducted at accredited laboratories and approved by competent authority;

d) *Performance criteria* — The performance criteria of any 3D printed components shall conform to the relevant Indian Standards for equivalent components. In the absence of any standards, an experiment-based approach shall be followed to satisfy the requirements for the specific element or component; and

e) *Special applications* — In the absence of any relevant standard, the engineer-in-charge, authorised to define the qualification requirements in accordance with the applicable Indian Standards, shall take decisions based on sound engineering judgement and established practice. The testing shall be conducted at accredited laboratories and approved by competent authority.

B-3 APPLICATION — NON-LOAD BEARING

B-3.1 Falsework/Formwork

3D-printed concrete may be used as stay-in-place (permanent) or temporary formwork for new concrete construction. The structural integrity of the formwork shall be either certified by a practicing structural engineer before the application or the formwork shall satisfy deformation limits and structural requirement mentioned in good practice [C-7(26)]. The formwork shall be designed by testing. The stay in place formwork shall not be considered as a part of the structural member.

B-3.2 3D Printed Concrete Building Blocks

The blocks can be solid as well as hollow, following the definition in accepted standard [C-7(27)]. The blocks shall have any external dimension greater than the corresponding dimension of a brick as specified in accepted standard [C-7(28)]. The size and the mass shall be such that it can be handled by as single person. In case of mechanized placement of the blocks, larger units can be used. The height of the block shall not exceed either its length or six times its width whichever is less. The faces of the block shall be manufactured based on the mutual agreement of the manufacturer and supplier/purchaser. Accepted standard [C-7(27)] shall be followed for considering the tests required to satisfy the performance criteria of the blocks.

B-3.3 Autoclaved 3D Printed Blocks

The autoclaved 3D printed solid blocks shall be tested based on the requirements mentioned in accepted standard [C-7(29)]. The blocks shall be of such dimensions and shape that they can be conveniently handled by a single person. The face of the block need not be plain, and the design shall be decided mutually by the manufacturer and supplier/purchaser.

B-3.4 Non-Load-Bearing 3D Printed Walls

3D printed concrete structures can be used as non-load bearing walls. The non-load-bearing walls can be divided into three types as mentioned as per Part C 'Structural Design, Section 4 Masonry' of this NBCS.

a) *Panel walls* — An exterior non-load-bearing wall in framed construction, wholly supported at each story but subjected to lateral loads;

b) *Curtain walls* — A non-load-bearing wall subject to lateral loads. It may be laterally supported by vertical or horizontal structural members, where necessary; and

c) *Partition walls* — An interior non-load bearing wall, one storey or part storey in height.

Such walls can be assessed for the performance requirements in the given application, and if necessary, testing of individual elements with necessary connection details can be done to ascertain lateral load resistance and intended performance.

B-3.5 Precast 3D Printed Panels

Precast 3D printed panels can be used for external or internal non-load-bearing walls. The panels shall be connected considering the guidelines provided in **8**. The printing and erection tolerance shall follow the permissible limits mentioned in **10.7**. The designing of the wall panels (including reinforcement) shall be provided by a certified structural engineer using this NBCS or following the concept of design by testing (in the absence of standardized design methods).

B-3.6 External Facing and Veneers

3D printed components can be used for external facing following the guidelines mentioned in good practice [C-7(30)]. Precast-facing concrete blocks shall generally conform to the requirements of accepted standard [C-7(27)] and, in addition, shall have special treatment regarding durability, colour and surface textures for the exposed facing. The face finish of slabs shall also be adequately waterproofed. The joint details, fixing technique and method of attachment shall be provided by a certified structural engineer following the concept of design by testing, in the absence of standardized design methods.

B-3.7 Acoustic

The acoustic treatment of non-industrial buildings, industrial establishments, and assembly spaces such as cinema halls or conference rooms is achieved through the design flexibility offered by 3D printing. The incorporation of air cavities between the inner and outer shells of walls contributes to the reduction of sound transmission between rooms. Panel and partition walls nay be printed with a suitable spacing between face shells as suggested in good practice [C-7(31)]. The semi-discontinuous and discontinuous construction mentioned in the good practice [C-7(31)] can be followed for non-industrial buildings. For industrial establishments and cinema halls or conference rooms, the reverberation time governs the acoustic experience. Good practices [C-7(32)] shall be followed to determine the reverberation time required for each application. The face of the walls and ceilings can be designed to govern the reverberation time while satisfying the requirements in the standards mentioned.

B-4 APPLICATION — LOAD BEARING

B-4.1 Design Philosophy

3D printed concrete structure shall satisfy the strength as well as serviceability requirements. The scope of this NBCS is limited to the load-bearing members in a building. Other structural applications are not considered for the purpose of this NBCS. Additionally, the durability and long-term behaviour of the printed structure shall be considered during design.

The load-bearing walls consist of a 3D printed shell and cast in-situ reinforced concrete core. In these cases, the 3D printed shell is considered to act integrally with the core. Depending on the application and the loading, the requirement of the reinforced concrete core may be done away with, in which case, the shell itself is capable of resisting both in-plane and lateral loads.

The design of load bearing walls shall be dependent on the load resistance mechanism. For the following two applications, the design using available information, and based on established principles of analysis and deriving load resistance, as commonly used in established codes of practice may be followed:

a) If the load resistance is derived from cast in-situ reinforced concrete core, (*see* Fig. 42); and

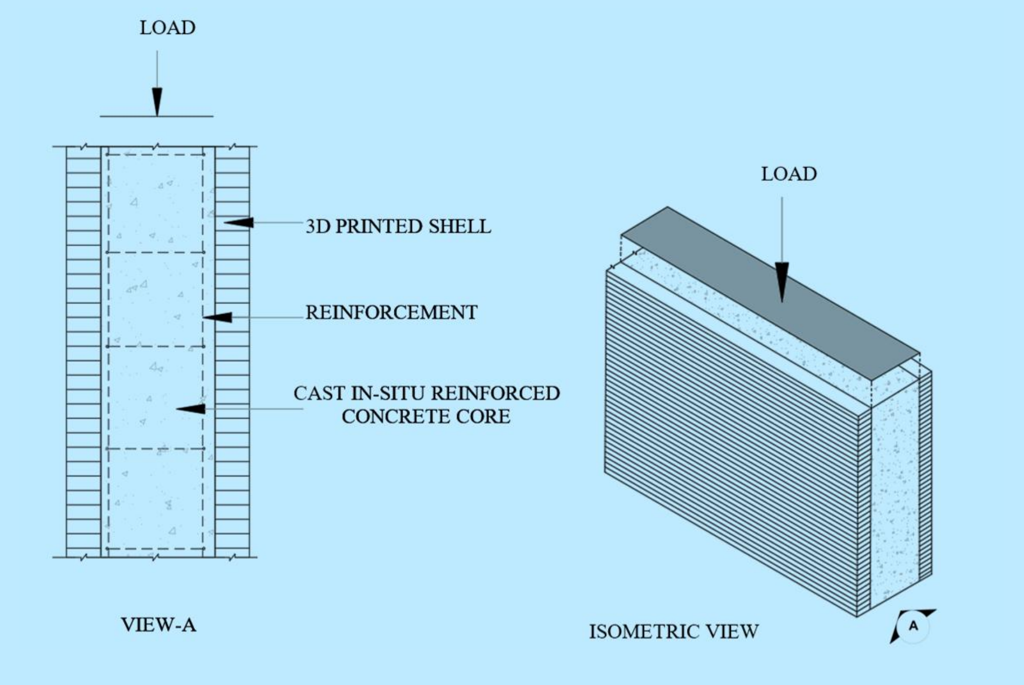


FIG. 42 LOAD RESISTANCE IS DERIVED FROM CAST IN-SITU REINFORCED CONCRETE CORE

b) If both 3D printed shell and cast in situ reinforced core are made using the same concrete mix, resulting in monolithic behaviour (*see* Fig. 43).

Where load resistance is derived using composite action between printed shell and cast in-situ core, design by testing the individual components may be followed.

All attempts to make the printed object behave in a ductile manner should be made to the extent possible, irrespective of the nature of usage.

NOTE — Specialized literature may be referred to while designing the test methods for the evaluation of structural walls. Alternatively, load-bearing 3D printed structures can be constructed with the approval of a certified external authority.

The use of load bearing walls is limited to gravity load. The use for load resistance subjected to earthquake loading as per good practice [C-7(20)] and **5** of Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS and the requirements of ductile detailing as per good practice [C-7(1)] are outside the scope of this annex. Design by testing approach may be followed for any specific application. Additionally, the foundation shall comply all the requirements of good practice [C-7(33)] and to any other relevant Indian standards.

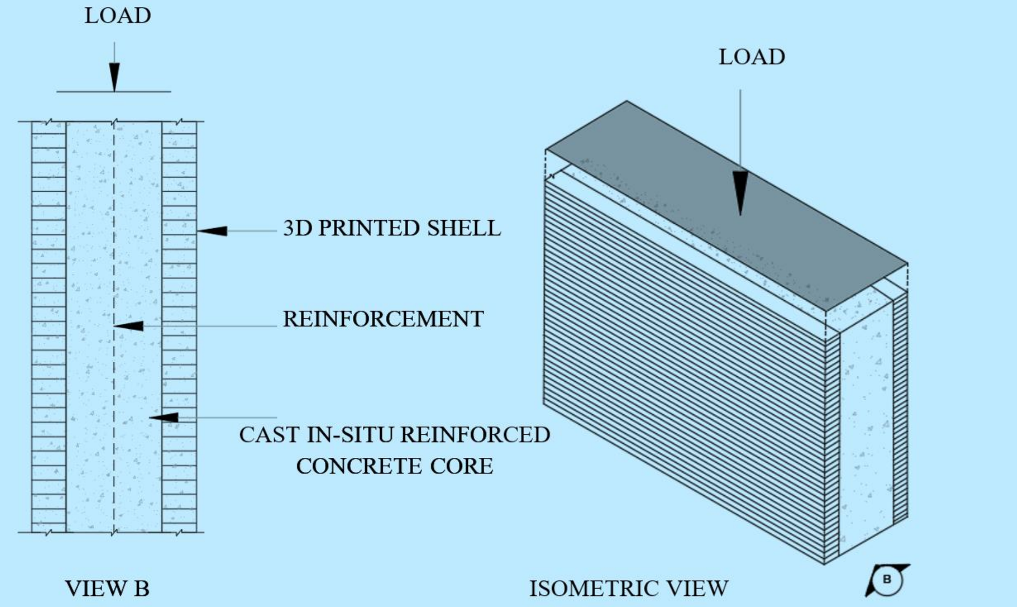

FIG. 43 LOAD RESISTANCE IS DERIVED FROM 3D PRINTED SHELL AND CAST IN-SITU REINFORCED CONCRETE CORE

B-4.2 Loads

The load criteria shall be as per Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS. The lateral and earthquake load shall be taken special care of while designing the load bearing structures. The components of the structures shall be tested at full scale individual element level with necessary boundary conditions.

B-4.3 On-Site and Off-Site Construction

In case of an on-site construction, the printer is expected to be stationed at the location and construction to be carried out in-situ. For off-site construction, panels/sub-parts of the structure are printed in a factory and assembled at the site. In such a case, particular attention is to be paid to the design of the connections, as per the prevailing standards and codes.

B-4.4 Load Bearing Wall

3D printed load bearing walls can be used for buildings up to a height where the effect of lateral load is not severe, which may be restricted to building of height of 12 m. For buildings beyond 12 m height, the structural design and construction methodology shall be approved by the competent authority. Special care shall be taken while designing the connection between wall to slab, wall to beam and wall to footing. The minimum effective thickness of the load bearing wall shall be 100 mm in accordance with the guidelines of Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS. The 3D printed load bearing wall can be considered as:

a) 3D printed perimeter (with or without printed internal rib filaments) and cast in situ concrete core. Depending on the application and extent of loading, these walls can be fully solid (that is with the core completely filled with cast in situ reinforced concrete), hollow (that is without any internal filling) or partially filled (with reinforced concrete in some of the cavities); or

b) Completely printed wall with no hollow space.

The cover depth of 3D printed wall shall consider exposure condition and fire resistance as per Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS. The cover depth should include the thickness of the 3D printed perimeter filament and the cover (if any) provided by the core concrete. The minimum reinforcement criteria laid down in Part C 'Structural Design, Section 5 Structural Concrete' 5 of this NBCS shall be followed. Horizontal reinforcement in the form of high yield strength deformed (HYSD) rebar or welded wire mesh or textile mesh shall be provided to connect the outer leaves to the inner core, when the design assumes a composite action of the 3D printed perimeter and the inner core. In other cases, the printed leaves shall be considered as stay-in-place formwork and shall not be taken as a part of the load-bearing wall. However, even in such cases, efforts should be made to ensure that spalling or collapse of the outer periphery does not occur in extreme events such as earthquakes.

The walls shall satisfy the strength and serviceability criteria of the load bearing walls as per Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS. If required, the design shall be on basis of testing of individual elements with necessary boundary conditions or connection details. For testing guidelines, specialist literature and publication may be referred if necessary.

NOTE — Specialist literature/publication may include those published by International Code Council, etc.

B-4.5 Load Bearing Column

Column shall be designed using as per Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS. If required, test results obtained by full scale testing of individual elements with necessary boundary conditions or connection details shall be used. Buckling load criteria shall be satisfied considering the end-restraint conditions by testing. A certified structural engineer shall design the column as per logical reasoning based on experimental evidence.

B-4.6 Shear Walls

The shear walls shall be solid walls designed as per the requirements of good practice [C-7(2)]. The design guidelines similar to that of load-bearing 3D printed walls shall apply. The performance of 3D printed shear walls under lateral and earthquake load shall be tested. The design shall be on basis of experimental outcomes by a certified structural engineer.

B-4.7 Load-Bearing Beams and Slabs

The 3D printed beam and slab shall satisfy the load and serviceability requirements mentioned in Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS. The flexural capacity of the printed beam shall be tested using 3-point and 4-point bending test at full-length-scale element level. The characteristic strength of the printable mix shall not be used to design the flexure member. The results from full-length-scale element level tests shall be used. A certified structural engineer shall design the flexural members as per the reports from the testing.

B-4.8 Foundation

A 3D printed foundation shall be designed following the design by testing method. The foundation can be printed in-situ or assembled at site like precast foundation after printing at the factory. The foundation shall be designed by a certified structural engineer while considering inputs from geotechnical engineers about the soil bearing characteristics. Durability requirements, as mentioned in good practice [C-7(2)], for the foundation shall be strictly satisfied.

If the outer perimeter of the foundation is only printed and the core is cast as conventional foundation, then the printed part shall not be taken into the load calculation and shall be treated as a formwork.

B-4.9 Retaining Wall and Basement

Retaining wall and basement shall be solid for load-bearing applications. Reinforcement strategy shall follow the guidelines mentioned for 3D printed load bearing walls.

B-4.10 Concrete-Reinforcement Bond Strength and Development Length

These are to be determined for each case and the structural engineer shall take into account the same while designing the reinforcement. The effect of layer time gap and moisture loss shall also be considered while designing the reinforcement. The bond between the rebar and the printed concrete shall be measured before designing the reinforcement.

B-4.11 Connections

Connections between the elements, including, but not limited to between two printed elements; printed non-structural element and cast in-situ structural reinforced concrete element; printed non-structural element and precast structural element; printed structural element and precast structural element; follow the requirements given in Part C ‘Structural Design, Section 5 Structural Concrete’ of this NBCS. If required, the connections shall be designed by testing. However, the connection between cast in-situ reinforced core and other structural elements shall follow standard design practice.

B-5 OTHER APPLICATIONS

B-5.1 Boundary Walls

The 3D-printed boundary wall shall not be a retaining wall or any load-bearing structure.

B-5.2 Design Elements for Outdoor Spaces

These elements shall comprise, but are not limited to, the following:

a) Pavement and other pedestrian movement spaces such as footpaths, plaza assembly spaces, kerb to footpath, steps and ramps;

b) Parking and vehicular movement corridors such as road dividers, road marking, etc;

c) Traffic management units such as gate/access control, barriers, traffic separators, etc;

d) Outdoor public conveniences such as seating, drinking fountains, toilet/washrooms, etc;

e) Shelter and kiosks such as bus shelters, police and telephone booth, food stall, information desk, etc;

f) Outdoor illumination such as street light pedestals, etc;

g) Tree guards, tree grates and planters;

h) Litter bins, and spittoons; and

j) Service utilities relating to water supply network, storm water network, sewerage system, irrigation network, etc.

These structures shall be designed by a certified structural engineer following the reports from experimental evaluation.

B-6 CURING

The printed structures shall be cured following the provisions mentioned in Part C ‘Structural Design, Section 5 Structural Concrete’ of this NBCS. However, curing shall be initiated at the early age to avoid plastic shrinkage cracks. Water spraying in the form of a fine mist must be started even before the initial set. At any given instance, the surface shall not be dry. The curing shall be done until the designed strength is reached for the 3D printed walls and slabs. Curing compounds can be used to reduce the number of days of water curing. The engineer-in-charge shall take the decision regarding the curing requirements based on experimental evidence.

B-7 QUALITY ASSURANCE AND QUALITY CONTROL

The following properties shall be assessed for determining the quality of the 3D printable concrete mix. The sampling shall be done as per Part C ‘Structural Design, Section 5 Structural Concrete’ of this NBCS:

a) The mechanical properties including cube compressive strength, elastic modulus, split tensile strength, and flexural strength of the concrete shall be tested following the method in accepted standard [C-7(34)]. The properties of water permeability, drying shrinkage, and rapid chloride permeability shall also be tested following the relevant Indian standards. The tests shall be performed on the specimens sawn/cored from printed samples. The anisotropy of the structure shall be tested along X, Y and Z coordinates. The test shall be conducted on the cast specimen also with the concrete used for printing the structure; and

b) Additionally, the bond strength of the layer shall be tested by extracting beam specimens of 40 mm × 40 mm × 160 mm from the printed structure, or a special test element. 3-point and 4-point bending test shall be performed on the extracted specimens with a minimum number of 5 specimens for each sample.

ANNEX C

(*Foreword and Clause* 6.5.2)

PREFABRICATED PREFINISHED VOLUMETRIC CONSTRUCTION (PPVC)

C-1 GENERAL

This annex provides a comprehensive guideline on prefabricated prefinished volumetric construction (PPVC) methods, materials, design standards and performance criteria for use by building professionals and other stakeholders involved in modular construction. This annex aims to facilitate the understanding and practical application of PPVC across various types of construction projects, including residential, commercial and industrial buildings. By outlining the key requirements and standards, this annex supports efficient and effective PPVC project planning, production, and assembly of PPVC to ensure high-quality, durable and sustainable modular structures.

This annex provides insights into essential aspects of prefabricated prefinished volumetric construction (PPVC), including design principles, manufacturing and installation practices, quality assurance, transportation and site assembly. It also highlights critical considerations for structural integrity, fire safety, environmental sustainability and inspection protocols, thereby promoting the adoption of best practices and supporting ongoing efforts to advance safe and innovative construction methods.

C-2 METHODOLOGY

The following points are considered while defining the application and performance guidelines.

C-2.1 Design

Design of PPVC modules considers both architectural and structural planning, taking into account modularization, alignment, and standardization of dimensions. It ensures that the modules comply with specifications for efficient on-site assembly, structural integrity and adherence to applicable building standards and design requirements.

C-2.2 Off-Site Manufacturing

The modules should be constructed in a controlled factory environment. This allows precise manufacturing with minimal errors and faster production times. Components, including concrete and steel modules, are cast, cured and finished with necessary fixtures, plumbing, and electrical setups before transportation to the construction site.

C-2.3 Transportation

Once manufactured, modules are carefully transported to the construction site. The transportation plan ensures that modules remain damaged and conform to transportation regulations, accounting for dimensions, weight and route restrictions.

C-2.4 On-Site Assembly

This stage involves the installation and connection of PPVC modules at the construction site. Modules are hoisted and secured in position, followed by finishing operations, including joint sealing and final inspections, to ensure that the assembled structure complies with all applicable quality and safety standards.

C-2.5 Modular Dimensions

PPVC modules should designed to fit within standard transportation limits to ensure easy delivery to construction sites. Common dimensions range from 3 m to 12 m in length, 2.5 m to 3.5 m in width, and 2.5 m to 4.5 m in height. Specific adaptations shall account for the maximum width (2.5 m), height (4.5 m including truck height), and length (up to 18 m) based on transportation guideline.

C-2.6 Transportability and Site Constraints

The size and weight of PPVC modules are influenced by on-site access, route clearance and crane requirements. The structure shall be modularized to ensure efficient on-site alignment and joining of modules, while minimizing the need for additional handling at the construction site.

C-2.7 Materials

a) *Concrete and steel modules* — PPVC modules are typically constructed from high-performance materials like reinforced concrete (RC) or steel. Reinforced concrete offers durability and structural integrity, whereas steel provides a lighter alternative, especially useful for high-rise buildings; and

b) *Enhanced material specifications* — Materials are chosen for performance under factory conditions and transportation stresses. For instance, high-strength/performance concrete (HPC) and steel conforming to relevant Indian Standard (such as Fe 500 or higher for reinforcement) are preferred. The use of sustainable materials, such as fly ash and other admixtures, is also encouraged to improve durability and reduce environmental impact.

C-2.8 Connections

Connections should be strong enough to secure modules under various stresses, including lifting, transportation, and environmental forces. Common PPVC connection methods include grouted couplers, wire loop boxes, dowel systems, and mechanical fasteners. These ensure that modules are securely integrated without compromising flexibility needed for seismic or wind forces.

Vertical joints (for stacking modules) and horizontal connections (for lateral stability) are essential for PPVC structures. These connections often involve interlocking systems or bolted end plates that provide stability while allowing for some movement to accommodate load and environmental stresses.

Connections should be designed to follow the Indian Standards for seismic and wind loads, such as good practice [C-7(35)] and **5** of Part C/Section 1 of this NBCS, to ensure safety and resilience under local conditions. Proper connection systems are necessary to transfer loads between modules and secure them as a unified structure.

C-2.9 Alignment

The alignment of prefabricated prefinished volumetric construction (PPVC) modules is critical to ensure that the final building is structurally sound and aesthetically pleasing. There are several key considerations to keep in mind when aligning PPVC modules:

a) The foundation on which the PPVC modules are placed should be level and square. If the foundation is not level, it can cause the modules to shift and potentially compromise the structural integrity of the building. Unless it is designed as a paper joint, a minimum 20 mm joint thickness shall be detailed between the top of the foundation and the PPVC module to account for site tolerances. The joint shall be later grouted with high strength grout as per design specification for structural integrity as well as continuity for functional performance;

b) Each PPVC module should be precisely aligned with the adjacent modules to ensure that the building is straight and true. This is typically achieved using alignment pins or other methods to ensure that the modules are aligned both vertically and horizontally. The erection tolerances shall be followed as per **10.7.6**;

c) Ensuring that the PPVC modules are level vertically is also critical to the structural integrity of the building. Laser levels and other tools can be used to ensure that the modules are plumb and aligned with the adjacent modules; and

d) The facade of the building, which includes windows, doors, and exterior finishes, should also be precisely aligned with the PPVC modules to ensure that the final building looks aesthetically pleasing.

C-2.10 Structural Design and Load Compliance

PPVC modules should comply with load standards as outlined in Part C ‘Structural Design, Section 1 Loads and Load Effects’ of this NBCS, for addressing dead loads, live loads, wind loads and other special loads requirements.

Modules should also meet seismic design requirements under **5** of Part C/Section 1 of this NBCS to ensure stability during earthquakes.

Structural elements for concrete and steel structures shall follow Part C 'Structural Design, Section 5 Structural Concrete' and Part C 'Structural Design, Section 6A Steel' of this NBCS, ensuring that all modules meet load-bearing and durability criteria. The Limit State Method is typically applied for PPVC modules, which includes safety factors to manage risks associated with live loads, dead loads and extreme environmental forces.

C-2.11 Material Standards

a) *Concrete and reinforcement compliance* — For concrete quality, PPVC construction shall follow Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS, including high-performance concrete or self-compacting concrete for durability. Reinforcements use deformed steel bars as per accepted standard [C-7(36)] for high-strength requirements, ensuring modules can withstand handling, transportation and on-site stresses; and

b) *Admixtures and aggregates* — Chemical and mineral admixtures should comply with accepted standards [C-7(5)] and Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS, which specify performance standards for durability and workability. Aggregates are selected as per accepted standard [C-7(4)], ensuring strength and proper gradation.

C-2.12 Fire Safety and Compartmentation

For fire resistance, PPVC structures shall comply with the requirements specified in Part F 'Fire and Life Safety' of this NBCS, including provisions for compartmentation. Each PPVC unit shall be provided with fire-rated walls, floors and doors, as required, to restrict the spread of fire and smoke and to ensure adequate means of egress and safety of occupants.

All materials used shall meet the relevant requirements of Part F 'Fire and Life Safety' of this NBCS for fire safety. Structural elements shall be designed to withstand high temperatures and achieve the required fire resistance in accordance with the relevant provisions of Part C/Section 5 of this NBCS.

C-2.13 MEP (Mechanical, Electrical, Plumbing) Standards

a) Electrical installations in PPVC buildings should meet the accepted standard [C-7(30)] and Part D 'Building Services/Section 2 Electrical and Allied Installations' of this NBCS, ensuring safe and reliable connections between modules. Additionally, accepted standard [C-7(38)] and Part D/Section 2 of this NBCS should be used for lightning protection systems to prevent electrical hazards; and

b) Plumbing systems follow good practice [C-7(39)] and Part E 'Plumbing Services, Section 1 Water Supply and Section 2 Drainage and Sanitation' for water supply and drainage, ensuring leak-proof, pressure-resistant pipes that meet durability and sanitation requirements in modular installations.

CI-2.14 Construction Tolerances

Construction tolerance limits in prefabricated prefinished volumetric construction (PPVC) refer to the allowable deviation from the intended design and specified dimensions. These limits are important to ensure that the final building is structurally sound and aesthetically pleasing. The construction tolerance limit in PPVC can vary depending on the specific materials and construction techniques used, as well as the local building standards and regulations. Permissible tolerances from the specified dimension of a PPVC module should conform to casting tolerances provided in **10.7.5**.

C-2.15 Performance Criteria

The performance criteria of any PPVC components should conform to the relevant Indian Standard for equivalent components. In the absence of any Indian Standard, the safety and durability of the specific element or component should be demonstrated through testing.

C-2.16 Special Applications

In the absence of any standards, the engineer-in-charge should make decisions based on logical reasoning and practical evidence. The test program should be conducted at accredited/approved laboratories and approved by statutory bodies.

C-3 APPLICATIONS

C-3.1 Residential and Commercial Buildings

PPVC modules for residential and commercial buildings shall be permitted for use in multi-storey structures and may be designed as either load-bearing or non-load-bearing units. Load-bearing modules shall be designed to resist vertical loads and shall satisfy requirements of stability and safety for multi-level configurations. Non-load-bearing modules shall be used as partitions or infill components. The provisions of Part F 'Fire and Life Safety' of this NBCS shall apply for fire safety requirements, while Part C 'Structural Design, Section 4 Masonry' of this NBCS shall govern structural requirements, sound insulation and seismic load-bearing capacity. The design shall ensure adequate connections and overall structural integrity of the system.

C-3.2 Educational and Healthcare Facilities

Modules are pre-finished to meet spatial needs, such as classrooms and patient areas, integrating critical systems like mechanical, electrical and plumbing (MEP) as per good practice [C-7(40)] and Part E 'Plumbing Services, Section 1 Water Supply and Section 2 Drainage and Sanitation' for water supply and drainage.

C-3.3 Industrial Buildings

PPVC in industrial buildings such as warehouses and factories requires modules engineered to meet the load-bearing and lateral resistance standards outlined in Part C 'Structural Design, Section 6A Steel' of this NBCS for structural steel and Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS for reinforced concrete. The modular units allow for open, high-capacity spaces that can bear substantial loads, with compliance to Part C 'Structural Design, Section 1 Load and Load Effects' of this NBCS for design loads, wind, snow loads and for seismic considerations. Structural configurations shall also align with fire safety standards as per good practice [C-7(19)] to facilitate efficient integration of services. This approach enables high-speed assembly, structural integrity and durability for industrial purposes while meeting all requirements.

C-3.4 Design Philosophy

PPVC structures should be designed to meet strength and serviceability requirements, ensuring structural integrity under the anticipated loads. This focuses on load-bearing applications within PPVC, excluding non-structural or purely aesthetic uses. Additionally, the design should account for durability and long-term performance, particularly as modules are prefabricated off-site and subjected to transportation and on-site assembly stresses.

Load-bearing PPVC modules typically consist of a reinforced concrete or steel core surrounded by a prefinished volumetric structure. The core provides essential stability, especially under vertical and lateral loads. In certain applications, the volumetric shell itself may be designed to carry both in-plane and lateral loads, with the core providing additional structural redundancy.

The design approach for load-bearing PPVC modules depends on the load resistance mechanism employed, as outlined below:

a) *Core-based load resistance* — Where the primary load resistance is provided by a reinforced concrete or steel core, which may be cast in-situ or prefabricated; and

b) *Monolithic module design* — Where the PPVC module's core and shell use a compatible concrete mix or reinforcement design to behave as a single monolithic unit under load.

For cases where the load resistance is derived from the combined action of the volumetric shell and the core, individual component testing is recommended to validate the composite action. Efforts to promote ductile behaviour are essential, ensuring that load-bearing PPVC elements respond safely under stress.

NOTE — Testing and certification can be carried out as per specialised literature (reference may be made to applicable standards/Codes of the International Code Council (ICC) for structural evaluation methods), or structures may be certified through recognized government bodies in India. The scope of this section is limited to gravity loads. For resistance to earthquake-induced forces and ductile detailing as per Part C/Section 1 and Part C/Section 5 of this NBCS, additional testing and validation may be required.

C-3.5 Loads

Load criteria for PPVC modules should conform to good practices, with particular attention to lateral and seismic loads. Structural components should be validated through full-scale testing of individual elements, ensuring that boundary conditions simulate actual applications. Testing should confirm that PPVC modules meet all load-bearing and serviceability requirements, as specified accepted standards, for safe deployment in permanent structures.

C-3.6 Foundations

A PPVC foundation should be designed following a design-by-testing approach to confirm compliance with all load-bearing and durability standards. The foundation may be cast in-situ or prefabricated off-site as a precast unit for on-site assembly. Design shall be overseen by a certified structural engineer, with essential geotechnical input to evaluate soil bearing capacity, ensuring that the foundation is appropriate for the specific site conditions. Durability requirements per ‘Structural Design, Section 5 Structural Concrete’ of this NBCS should be strictly observed to maintain long-term performance and stability under applied loads.

To ensure a secure connection between the PPVC modules and the foundation, appropriate dowel bars or reinforcement should be incorporated into the foundation design. These reinforcement provisions should align with the load transfer requirements and provide structural continuity between the foundation and the modular components. Proper anchorage and placement of dowels will prevent differential movement and provide stability for the assembled structure.

C-4 CURING

As PPVC modules are manufactured in an off-site, controlled environment, advanced curing methods may be implemented to expedite the process and ensure consistent quality. In addition to following ‘Structural Design, Section 5 Structural Concrete’ of this NBCS, rapid curing techniques, such as steam curing, warm water curing, or the use of curing compounds, can be employed to accelerate strength development. These methods enable the modules to achieve the desired performance levels within a shorter time frame, which is critical for modular construction timelines.

The curing approach should ensure that modules reach their designed strength before transportation to the construction site. The decision on curing methods and duration should be based on testing and performance requirements, as determined by the supervising engineer, to guarantee durability and structural integrity.

C-5 QUALITY ASSURANCE AND QUALITY CONTROL

Compliance with good practices includes ongoing quality checks at both the manufacturing and construction stages. Regular inspections, as per relevant provisions this NBCS and relevant Indian Standards, to verify structural integrity, alignment and safety of each module, especially focusing on connections and material durability over time.

C-6 MAINTENANCE AND INSPECTION

Regular inspection and maintenance protocols should be set to identify wear or structural concerns in connections and external finishes, ensuring longevity and safety as outlined in relevant provision of this NBCS.

ANNEX D

(*Foreword and Clause* 6.6)

GUIDELINES FOR DESIGN FOR MANUFACTURING AND ASSEMBLY (DFMA)

D-1 The concept of design for manufacturing and assembly (DFMA) emphasizes the use of precast and prefabricated building components. The underlying principles of DFMA call for more efficient building design and construction detailing, especially in the area of precast concrete connection designs, so as to minimize the amount of wet works on-site.

To develop an advanced pre-cast concrete system (APCS), it is important for the various building disciplines to first understand the functional considerations, building aesthetics, and design approaches. This understanding will enable the conceptualization and development of the APCS design, ensuring it meets the project specifications. It is essential that the APCS design is coordinated with the manufacturing specification for components, construction planning and site work to ensure seamless integration and efficient construction processes.

D-2 DESIGN BASIS FOR ADVANCED PRECAST CONCRETE

The following are key principles of efficient construction using APCS systems:

a) *Modular architecture layouts* — Designing buildings in modules to allow for greater use of precast and prefabricated components, reducing on-site construction time and costs;

b) *Precast repetition* — Using standard precast elements repeatedly throughout the building, simplifying the construction process and reducing the need for customization;

c) *Efficient structural design* detailing (standardize design and detailing) — Designing precast connections that can be easily assembled on-site, reducing the need for wet works and temporary supports;

d) *Quick assembly detailing* — Designing connections and components that can be quickly and easily assembled on-site, reducing construction time and costs; and

e) *Limited use of temporary supports* — Designing precast components that can be assembled without the need for temporary supports, further reducing construction time and costs.

D-3 FACADE STANDARDIZATION

Architectural design is a process to create a built environment with functionality for human comfort and sustainability through art and engineering design. In an effective precast concrete construction, the external facade design is generally achieved through optimal standardization in the following:

a) *Shapes* — FRP/rubber-lined moulds can be used to create various shapes for precast concrete components;

b) Textures such as sandblasted or acid-etched finishes can also be added to enhance the visual appearance of the precast components;

c) Different colours can be achieved using pigments or concrete colours, allowing for a wide range of design options;

d) *Repetition* — Standard precast elements can be repeated throughout a building's facade, making construction faster and more efficient;

e) *Modular design* — It allows for the precast components to be easily assembled on-site, reducing the need for wet works and temporary supports;

f) *Small complex facade panels* — Glass reinforced concrete (GRC) can be used instead of concrete for small complex facade panels;

g) *Complex facade as a separate add-on* — Complex facade elements can be designed and manufactured separately from the building structure, allowing for easier handling and installation on-site;

h) *Layouts rotated over mirrored* — Rotating layouts over mirrored elements can make use of the same assembly for construction; and

j) *Checklists* — Checklists can be used to ensure good precast arch design, covering aspects such as structural integrity, aesthetic appeal and ease of construction.

D-4 STRUCTURAL DESIGN

Structural design has a direct impact on the ease of precast concrete manufacturing and site erection works. The key consideration for structural system design solutions are:

a) *Simple design and detailing* — Precast concrete components should be designed with simple connections that can be easily assembled on-site, reducing construction time and costs;

b) *Commercial - long spans* — Precast concrete components can be used for long-span commercial buildings, such as warehouses or shopping centres;

c) *High rise residential* — In high-rise residential buildings, precast concrete wall panels can be used in conjunction with precast concrete floor slabs;

d) *Low/mid rise residential* — In low to mid-rise residential buildings, precast concrete wall panels can be used with precast concrete floor slabs and beam-column combinations; and

e) *Design to cater for temporary loads during construction* — The structural design should cater for temporary loads during the construction phase, such as the weight of equipment and construction workers.

D-5 TYPES OF STRUCTURAL SYSTEMS

All semi or full precast concrete structural systems need clear consideration for stability. It may take one of the following forms:

a) *Skeletal frames* — Precast concrete components can be used to create skeletal frames, with columns and beams connected with precast framed connections;

b) *Load bearing walls* — Precast concrete wall panels can be used as load-bearing walls, supporting the weight of the floors and roof;

c) *Load bearing facade* — In a load-bearing facade system, the precast facade concrete panels bear the weight of the building and transfer the loads to the foundation independently to the core of the structure;

d) 3-*D boxes* — Precast concrete components can be used to create 3-D boxes, with precast walls, floors, and roofs forming the 3-D building unit;

e) *Mixed systems* — A combination of precast concrete components can be used to create mixed systems, such as precast concrete walls with cast-in-place concrete floors; and

f) *Checklists for good precast structural design* — Checklists can be used to ensure good precast structural design, covering aspects such as strength and durability, fire resistance, seismic design and ease of construction.

D-6 CONNECTIONS

Connection in precast concrete construction must be designed to take the forces derived in the structural modelling. To achieve work efficiency, the design approach should consider the following aspects:

a) *Standardized connections* — Standardized precast concrete connections are designed to be easily designed, manufactured and assembled on-site;

b) *Ease of erection* — Precast concrete connections should be designed with ease of erection in mind, to ensure that they can be quickly and safely assembled on-site;

c) *Simple and minimalistic* — Simple and minimalistic connections are preferred in precast concrete construction, as they are more efficient and cost-effective;

d) *Checklists for good connection systems* — Checklists can be used to ensure good precast concrete connection systems, covering aspects such as durability, strength, and ease of assembly; and

e) *Innovative connections* — Innovative precast concrete connections can be used to create unique and complex structures, such as hybrid steel and precast systems or lotus root precast systems. These connections can offer advantages such as improved structural performance, and reduced construction time.

D-7 DESIGN OF CONNECTIONS

Design methods for joints in precast construction have been covered by various international technical journals and published academic research papers. They briefly cover the connections listed below:

a) *Corbel-beam end joint* — A hidden mechanical connector can be used for the corbel-beam end joint, similar to hanger connections;

b) *Column/wall base mechanical connections* — Column shoes and wall shoes with anchor bolts can be used for mechanical connections at the base of columns and walls;

c) *Wall to wall connections* — Wire loops can be used for wall to wall connections;

d) *Beam to beam* — Steel hangers can be used for connecting precast concrete beams; and

e) *Rigid beam-column* — Top steel couplers and bottom steel welded connections can be used for rigid beam-column connections, ensuring that the connection is strong and can resist bending and shear forces.

D-8 CONNECTION DESIGN CONCEPT

This can cover the following:

a) Load paths — Diaphragm, slab to wall/column paths, slab-beam shear connection;

b) Frame behaviours;

c) Accidental loads, progressive collapse;

d) Tie design forces;

e) Tie continuity — Laps, tie with enclosed links; and

f) Tie anchorages with other ties.

D-9 DESIGN EXAMPLES

a) Beam half joint (dap connection);

b) Beam half joint (hanger/beam shoe connection);

c) Corbel (conventional);

d) Peikko corbel;

e) Column base — Splice sleeve/grouted couplers;

f) Column base — Shoe connection;

g) Wall base — Splice sleeve/grouted couplers;

h) Wall base — Shoe connection;

j) Wall —Wall joint – Shear keys only;

k) Wall — Wall joint – With loop reinforcement;

m) Beam steel hangers — Generic;

n) Beam steel hangers — Peikko;

p) Proprietary mechanical connections;

q) Column to base and column to column;

r) Beam to column — Moment connection;

s) Beam to column — Simply supported;

t) Beam to beam;

u) Wall to wall — Vertical and horizontal connections; and

v) Landing slabs — TSS.

COMMON DEFECTS AND REMEDIES

F-1 As defects in precast concrete elements result in direct and indirect cost in terms of rectification and construction time, it is worthwhile to ensure that they are produced and handled in a way to avoid/reduce such incidences. Table 19 illustrates some of these common defects, their causes and preventive and remedial measures.

Table 19 List of Common Defects and Recommended Remedial Measures

(*Clause* F-1)

Sl No. (1)	Common Defects (2)	Possible Causes (3)	Recommendations (4)	Remedial Measures (5)
i)	*Dimensional deviation*: a) Variation in the dimension of precast elements would affect the joint alignment between these elements when erected; and b) Precast slab element may warp due to insufficient concrete strength at lifting or improper storage condition.	a) Mould forms may not be sufficiently rigid to maintain specified tolerances during concrete placement; b) Precast elements may not have gained sufficient concrete strength when demoulded; c) Top surface finish of precast elements may not be properly levelled and trowelled during production which result in differential thickness; and d) Precast elements (especially slender wall or slab panels) may be subjected to undue stress and deformation when they are not properly supported during storage.	a) Regular check on the dimensions and rigidity of mould forms before casting operations. As a general guide the recommended thickness for steel mould are: 1) 4.5 mm — Up to 50 castings; 2) 6 mm — Up to 100 castings; and 3) 9 mm — Up to 200 castings. Mould forms conditions will deteriorate with time and usage. They should be repaired, stiffened or replaced when needed. b) Cube tests should be conducted to ascertain the concrete strength of elements before demoulding;	a) For minor deviation, corrective measures such as surface grinding, trimming/ hacking and skim coat application can be appropriately used to remedy the situation; and b) Precast elements that are not within acceptable tolerance limits and have significant effects on the structural integrity or architectural performance should not be used.

Table 19 (*Continued*)

Sl No.	Common Defects	Possible Causes	Recommendations	Remedial Measures
(1)	(2)	(3)	(4)	(5)
			c) Spreading and levelling of concrete placement using appropriate tools such as structural screeder; and d) Precast elements should be properly stored and stacked at designated points using suitable support spacers and frame rack system.	
ii)	Cracks	a) Precast elements may not have gained sufficient concrete strength before demoulding; b) Cracks may have occurred during initial lifting due to friction between the elements and the casting mould forms; c) Thickness of the precast elements may be too thin (70 mm or less) for safe demoulding and handling; and d) Cracks may have occurred during erection due to lack of planning and provisions for the precast panel geometry, crane rigging configuration and location of openings.	a) Proper curing method, curing time and temperature should be maintained; b) Cube tests should be conducted to ascertain the concrete strength of elements before demoulding; c) Appropriate form release agents should be used and uniformly applied onto the mould surface to minimize friction; d) Sectional thickness of precast elements should be increased to accommodate demoulding and handling stresses; e) Proper handling techniques should be adopted; f) Sufficient lifting points should be used to minimize over-stressing on certain areas;	a) All cracks should be examined by a qualified engineer to determine if they present a structural problem; b) Depending on the locations and seriousness of the cracks, different repair methods can be used to make good the affected precast elements; and c) Hairline cracks (not more than design crack width) can be repaired by cutting V-groove of specified minimum depth along the crack-lines, followed by patching subject to location and length of the crack in relation to length of units and not having adverse effect on the structural strength of the unit. For surface cracks (more than design crack width) or through cracks, epoxy injection method should be used

Table 19 (*Continued*)

Sl No. (1)	Common Defects (2)	Possible Causes (3)	Recommendations (4)	Remedial Measures (5)
			g) Additional reinforcing bars should be placed around the opening and odd corners; and h) Temporary stiffeners for openings should be provided during erection.	to ensure that the cracks are completely bound and filled with epoxy.
iii)	Chip-off and damages	a) Chip-off at panel edges are usually caused by the hard bearing at support or excessive force exerted on the elements when handling; and 4) Improper storage method.	a) Precautions should be taken to avoid damaging the elements during placement on vehicle, travel to site and during the unloading operation. Bearing pads should be used to cushion the contact areas from damage; b) The storage area should be relatively flat and dry; c) Precast elements should be properly stored and stacked at designated points using suitable support spacers and frame rack system; d) The casting slab or mould form should be thoroughly cleansed, levelled to achieve a smooth surface; e) The coverage of form release agents should be adequate and applied uniformly onto the mould surface;	a) Remove all loose concrete and wash off any dust or dirt in the affected area; b) Apply bonding agent to affected concrete surface; c) Welded wire mesh can be included to provide support for the patch mix concrete or grout; d) Patch mix composition or grout should be consistent with the strength requirements of the adjacent concrete; e) Formwork should be placed whenever it is necessary to contain the patch mix or grout; and f) The affected area should be protected from any disturbance during the curing period.

Table 19 (*Continued*)

Sl No. (1)	Common Defects (2)	Possible Causes (3)	Recommendations (4)	Remedial Measures (5)
			f) Spacers of the correct sizes should be used and well secured to maintain the concrete cover required during casting; g) Lifting inserts and concrete strength of elements should be of adequate capacity for the intended lift. Proprietary products for safe and efficient handling may be used for this purpose; and h) Lifting inserts or hooks should be inspected for proper location. They should be fastened to specified depth prior to concrete placement.	
iv)	Honeycomb and excessive pinholes	a) Poor concrete compaction due to ineffective vibration or rebars congestion; annd b) Grout leakage along the perimeter of side forms due to: 1) Loose or missing bolts, fixing pins; 2) Damaged rubber gasket seal; 3) Mould part, if defective.	a) Proper compaction methods should be adopted and carried out; b) Concrete mix design and workability should bereviewed and adjusted when needed; c) Appropriate concrete vibrator such as clamp-on form vibrator may be used to attain better compaction; d) Rebar congestion can be alleviated by having larger size (that is, lesser number) rebars or by increasing the sectional	a) Remove all loose concrete and wash off any dust or dirt in the affected area; b) Apply bonding agent to affected concrete surface; c) Welded wire mesh may be included to provide support for the patch mix concrete or grout; d) Patch mix composition or grout should be consistent with the strength requirements of the adjacent concrete;

Table 19 (*Continued*)

Sl No.	Common Defects	Possible Causes	Recommendations	Remedial Measures
(1)	(2)	(3)	(4)	(5)
			dimensions of the elements where possible; e) Mechanical couplers or sleeves can be used to simplify the reinforcement layout and to minimize rebar congestion; and f) Defective mould forms and accessories should be repaired or replaced to prevent grout leakage during concrete.	e) Formwork is to be put up where it is necessary to contain the patch mix or grout; and f) The affected area should be protected from any disturbance during the curing period.
v)	*Missing or wrong details* — such as cast-in items, architectural nib and groove details, lifting hooks, reinforcement/starter bars/block- out/corrugated pipes.	a) Items may not have been included in the shop drawing; and b) Quality checks may not be properly in place.	a) All items should be reflected in the shop drawings for production. Any changes should be made known to the production team; and b) The use of checklists during inspection can help to ensure that all items specified in the drawing are included before casting.	a) Certain details such as missing starter bars/reinforcement and lifting hooks can be replaced by welding additional reinforcement bars after hacking off the concrete at the affected area; and b) Other items such as cast-in items, groove and block-out can be provided by chasing or chiselling out the face of the precast panels.
vi)	Strand slippage which exceed allowable design values (applicable to pre-stressed elements only) (Slippages of pre-stressing strands can be detected by visual inspection).	a) Insufficient bond strength between concrete and the pre-stressing strands; and b) Poor compaction of concrete around pre-stressed strands.	a) Required concrete strength of the precast elements should be attained and verified by cube test results before de-tensioning of strands; b) Proper compaction method should be adopted and carried out during casting;	a) It is not possible to rectify the elements from strand slippage; and b) Design verification should be carried out to ascertain the reduced capacity of the elements due to slippage, if adopted.

Table 19 (*Concluded*)

Sl No. (1)	Common Defects (2)	Possible Causes (3)	Recommendations (4)	Remedial Measures (5)
			c) Concrete mix design and workability should be reviewed and adjusted when needed; and b) Appropriate concrete vibrator to attain better compaction may be provided.	
vi)	Alignment	a) Inaccurate setting out and positioning of precast. elements during erection; and b) Deviation in the dimensions of the precast element.	a) Appropriate surveying and levelling equipment should be used to achieve better alignment; b) Required alignment and level should be confirmed before permanent jointing; and c) Critical dimensions of precast concrete elements should be verified before installation.	a) Minor adjustments of the element/panel alignment can be done during installation. However the effects on the final alignment and deviation of the building should be evaluated; b) For minor deviations, corrective measures such as surface grinding, trimming/ hacking and skim coat application can be appropriately used to rectify the precast elements before installation; and c) Precast elements that are not within acceptable tolerance limits and have significant effects on the structural integrity or architectural performance should not be used.

ANNEX G

(*Foreword*, *Clauses* 5, 7.1, 10.1.2, 10.9.1 *and* 11)

SUSTAINABILITY IN PRECAST CONCRETE CONSTRUCTION

G-1 GENERAL

This annex presents sustainable practices in precast concrete construction, emphasizing methods for reducing environmental impacts, promoting resource conservation and ensuring long-term viability. The following key sustainability factors can enables the adoption of greener and efficient solutions provided the challenges involved are appropriately addressed.

G-2 USE OF RECYCLED AGGREGATES IN PRECAST CONCRETE

G-2.1 Environmental Benefits

G-2.1.1 *Conservation of Natural Resources*

By reusing construction and demolition debris as recycled aggregates, the need for extracting virgin raw materials like sand and granite is significantly reduced, preserving ecosystems and minimizing environmental disruption.

G-2.1.2 *Reduction in Energy Use*

Recycled aggregates require less energy to process compared to natural aggregates, which leads to a lower carbon footprint during production. This also reduces the energy demand associated with quarrying, transportation and processing.

G-2.1.3 *Circular Economy Impact*

Incorporating recycled aggregates into precast concrete non-structural components-such as paving slabs, kerbs, and drainage of systems, etc, supports a circular economy, minimizing waste sent to landfills and promoting the reuse of construction materials.

G-2.2 Challenges and Innovations

G-2.2.1 *Ensuring Consistent Quality*

Recycled aggregates may exhibit variability in size and composition, potentially impacting concrete strength and durability. Innovations in sorting, crushing and refining technologies can improve the consistency and reliability of recycled aggregates.

G-2.2.2 *Efficient Use of Water*

In general, excessive water is required to be used while using recycled aggregate and can have negative environmental impacts. By adopting optimized mix designs and water-efficient technologies, the water demand for concrete production can be significantly reduced.

G-2.2.3 *Advancement in Sustainable Mixes*

New research into mix designs is focusing on achieving better integration of recycled aggregates without compromising the material’s strength or durability. This can lead to a more sustainable, high-performance concrete product.

G-3 ADOPTION OF RENEWABLE ENERGY SOURCES

G-3.1 Environmental Benefits

G-3.1.1 *Decarbonizing Operations*

Shifting precast concrete manufacturing facilities to renewable energy sources, such as solar, wind and hydropower, significantly reduces reliance on fossil fuels, helping to lower overall greenhouse gas emissions and mitigate climate change impacts.

G-3.1.2 *Electric and Hybrid Machinery*

By replacing conventional diesel-powered equipment with electric and hybrid alternatives, the precast concrete industry can reduce air pollution and carbon emissions associated with construction machinery.

G-3.2 Challenges and Innovations

G-3.2.1 *High Initial Costs*

The transition to renewable energy systems and low-emission machinery involves substantial initial investment. However, long-term operational savings, combined with available financial incentives for green technologies, can help offset the upfront costs.

G-3.2.2 *Energy Storage and Smart Grids*

Installing energy storage solutions, such as batteries, in conjunction with on-site renewable energy systems can help mitigate energy supply issues during periods of high demand or when renewable energy generation is low, further reducing dependence on the traditional energy grid.

G-4 REDUCING SITE POLLUTION AND WASTE

G-4.1 Environmental Benefits

G-4.1.1 *Waste Minimization*

Precast construction reduces on-site waste generation because most components are manufactured off-site in controlled factory settings. This reduces generation of waste and their dispersal at landfills and minimizes the potential for soil and water contamination and helps in achieving undisturbed site.

G-4.1.2 *Reduced Emissions and Noise Pollution*

Precast methods reduce the need for heavy on-site machinery and long construction timelines. As a result, there is less air pollution, noise pollution, and disturbance to nearby ecosystems or communities.

G-4.2 Challenges and Innovations

G-4.2.1 *Reducing Transportation Emissions*

Transporting precast components to construction sites can contribute to emissions, especially when distances are long. This can be minimized by optimizing transportation logistics, using hybrid or electric vehicles and focussing on the use of modular components that reduce transportation needs.

G-4.2.2 *On-Site Pollution Prevention*

During installation, on-site pollution, such as dust or runoff, can still occur. Simple practices like water misting to suppress dust and covering concrete surfaces to prevent runoff can significantly reduce the environmental impact of installation activities.

G-5 USE OF SUPPLEMENTARY CEMENTITIOUS MATERIALS (SCMs) AND OPTIMIZED CONCRETE MIXES

G-5.1 Environmental Benefits

G-5.1.1 *Low-Carbon Alternatives to Cement*

Replacing traditional Portland cement with supplementary cementitious materials (SCMs) such as fly ash, slag, or natural pozzolans can drastically reduce the carbon footprint of concrete production by minimizing the need for energy-intensive cement manufacturing.

G-5.1.2 *Efficient Resource Use*

Advanced mix designs, including high-performance concrete (HPC) and ultra-high-performance concrete (UHPC), allow for the reduction of material consumption without sacrificing strength or durability. These innovations help to optimize the use of raw materials, ensuring sustainability in production.

G-5.2 Challenges and Innovations

G-5.2.1 *Durability and Performance*

While reducing cement content or using alternative binders can lower the carbon footprint, it is essential to ensure the long-term durability and performance of the concrete.

G-5.2.2 *Geopolymer Concrete*

Geopolymer concrete, made from industrial by-products has a lower carbon footprint compared to traditional cement-based concrete and can be used in precast applications without compromising strength and durability.

G-6 SUSTAINABLE DESIGN AND PRODUCTION OPTIMIZATION

G-6.1 Environmental Benefits

G-6.1.1 *Material Efficiency through Design*

Precast elements can be optimised for material efficiency by carrying out optimum design. Building information modelling (BIM) allows for detailed digital models that reduce waste during both the design and construction phases.

G-6.1.2 *Modular and Prefabricated Systems*

The use of modular designs with standardization in precast construction can reduce material waste, reducing production time, reuse of mould and optimize the process of precasting.

G-6.2 Challenges and Innovations

G-6.2.1 *Customization versus Standardization*

While standardization helps reduce waste and increase efficiency, some projects require customised solutions. The challenge lies in finding a balance between benefits of standardized components and the need for bespoke, project-specific designs.

G-6.2.2 3*D Printing and Additive Manufacturing*

Emerging technologies like 3D printing could revolutionise precast construction (*refer* Annex B). By using digital fabrication techniques, custom shapes and optimized designs can be produced efficiently, with less material wastage.

G-7 TRANSPARENCY, CERTIFICATION AND ETHICAL PRACTICES

G-7.1 Sustainability Governance

G-7.1.1 *Environmental Certifications*

Precast manufacturers and construction companies can pursue certifications such as environmental management systems, to demonstrate their commitment towards achieving sustainability. These certifications set a global benchmark for eco-friendly practices in construction.

G-7.1.2 *Ethical Sourcing and Labour Practices*

Sustainable construction practices require ethical sourcing of materials, ensuring that raw materials are extracted responsibly and workers are treated fairly. This also includes adherence to applicable labour and governance standards/practices.

G-7.2 Challenges and Innovations

G-7.2.1 *Data Transparency*

As consumer and regulatory demand for sustainability data increases, companies are under pressure to disclose their environmental impacts. Technologies like block-chain offer innovative solutions for ensuring transparency and accountability in reporting environmental performance.

G-7.2.2 *Community and Stakeholder Engagement*

Actively engaging with local communities, government bodies, and customers to ensure that sustainability goals align with the social expectations and needs of stakeholders.

ANNEX H

(*Clause* 7.9.4.8)

DESIGN AND DETAILING GUIDELINES FOR PRECAST STRUCTURES WITH HOLLOW CORE SLABS

H-1 GENERAL

This annex presents the design guidelines and detailing parameters essential for structures using hollow core slabs as the flooring system. This annexure ensures that all parameters pertaining to structural stability and end user safety of hollow core slab systems are attended to.

H-2 DESIGN GUIDELINES

H-2.1 Hollow core slabs are to be designed as a simply supported slab system. The use of hollow core slabs is not permitted as a continuous flooring system.

H-2.2 Hollow core slabs are to be mandatorily designed using structural topping as mentioned in **6.3.6.1**. This topping shall be considered acting composite with the hollow core slab provided conditions mentioned in **6.3.6.3** are met.

H-2.3 For flooring systems consisting of hollow core slabs, only the structural topping shall be considered as part of the diaphragm as noted in **6.3.6.3**. No part of the hollow core slab shall be considered as part of diaphragm or considered participating in lateral load transfer. Structural topping design to follow guidelines as prescribed in **7.10.8**.

H-2.4 The design engineer is to assess the torsional rotation of the hollow core slab caused by the differential settlement of the slab supports. Special attention is to be undertaken by the structural engineer since hollow core slabs have limited torsional resistance capacity.

H-3 DETAILING PARAMETERS

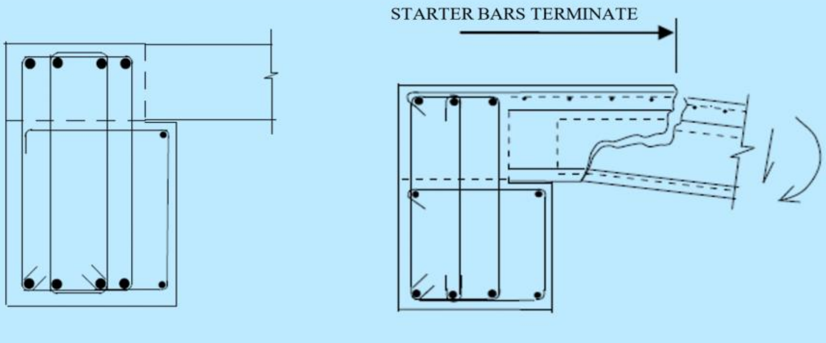
H-3.1 Low friction bearing shims or strips are to be placed under the hollow core slabs to mitigate the formation of flexural crack close to the support in the hollow core element and to mitigate spalling of support ledge concrete.

H-3.2 Concrete ledges to be used as bearing support for hollow core slabs must have the ledge reinforcement tied with the primary supporting beam or wall as shown in Fig. 57A.

H-3.3 Hollow core slabs to have minimum bearing of 80 mm to mitigate loss of support due to spalling and relative movement of the slabs.

H-3.4 Nominal starter bars must extend for a length of 600 mm from the face of the supporting members and tied to the structural topping reinforcement to mitigate failure due to negative moments close to the support during seismic events as shown in Fig. 57B. Starter bar reinforcement diameter may be 8 mm for slabs up to 300 mm depth and 10 mm for slabs over 300 mm depth at a spacing not more than 250 mm.

H-3.5 Structural topping to be preferably reinforced with reinforcement with elongation more than 14.5 percent to mitigate brittle failure of topping. Welded mesh may be permitted as topping reinforcement provided the mesh is fabricated from reinforcement having elongation more than 14.5 percent.

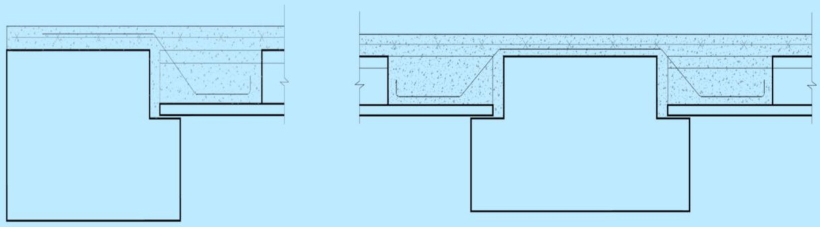


57A) LEDGE REINFORCEMENT TIED TO SUPPORTING MEMBER

57B) NEGATIVE FLEXURAL MOMENT FAILURE NEAR TO SUPPORT FACE

FIG. 57 DETAILING FOR HOLLOW CORE SLAB AND SUPPORTING ELELMENTS

H-3.6 A minimum of 2 cores to be opened for a length of 600 mm at both span ends of the hollow core slab, they are to be reinforced with 8 mm reinforcement for slabs up to 300 mm depth and 10 mm for slabs over 300 mm depth and filled simultaneously with the structural topping concrete. Figure 58 elaborates on the detailing that may be adopted at open core locations.

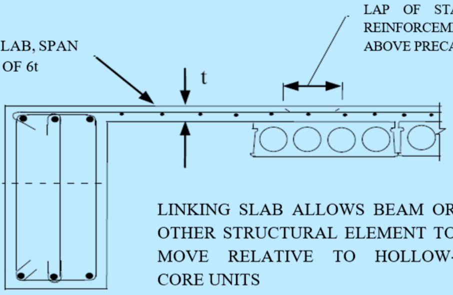


58A) OPEN CORE REINFORCEMENT AT END SPAN

58B) OPEN CORE REINFORCEMENT AT INTERMEDIATE SPAN

FIG. 58 DETAILING FOR HOLLOW CORE SLAB AT OPEN CORE LOCATION

H-3.7 Linking slabs to be provided to connect structural members to non-bearing ends of hollow core slabs. The length of the linking slab to be a minimum of 6 times the structural topping thickness as described in Fig. 59. The depth of the linking slab will be as per structural or load requirements.



LINKING SLAB, SPAN MINIMUM OF 6t

LAP OF STARTER BARS TO REINFORCEMENT IN TOPPING ABOVE PRECAST UNIT

LINKING SLAB ALLOWS BEAM OR OTHER STRUCTURAL ELEMENT TO MOVE RELATIVE TO HOLLOW-CORE UNITS

FIG. 59 DETAILING FOR LINKING SLAB AT HOLLOW CORE SLAB AND STRUCTURAL MEMBER

LIST OF STANDARDS

The following list records those standards which are acceptable as 'good practice' and 'accepted standards' in the fulfilment of the requirements of this NBCS. The latest version of a standard shall be adopted at the time of enforcement of this NBCS. The standards listed may be used as a guide in conformance with the requirements of the referred clauses in this NBCS.

In the following list, the number appearing in the first column within parentheses indicates the number of the reference in this Section.

	IS No.	*Title*
(1)	IS 13920 : 2016	Ductile design and detailing of reinforced concrete structures subjected to seismic forces — Code of practice (*first revision*)
(2)	IS 456 : 2000	Plain and reinforced concrete — Code of practice (*fourth revision*)
(3)	IS 1343 : 2012	Prestressed concrete — Code of practice (*second revision*)
(4)	IS 383 : 2016	Coarse and fine aggregate for concrete — Specification (*third revision*)
	IS 456 : 2000	Plain and reinforced concrete — Code of practice (*fourth revision*)
(5)	IS 9103 : 1999	Concrete admixtures — Specification (*first revision*)
	IS 456 : 2000	Plain and reinforced concrete — Code of practice (*fourth revision*)
(6)	IS 10262 : 2019	Concrete mix proportioning — Guidelines (*second revision*)

FOREWORD

This NBCS (Part C/Section 8) deals with the use of glass in buildings. Glazing has become an important item in building construction. Glass, the primary glazing element has to be selected to cater to several requirements and the glazing has to be designed to meet various engineering requirements. Fixing of glass, a specialized operation, when properly done, will avoid the hazards of broken glass. Growing trend in resorting to glazed windows/doors in buildings and structures has considerably increased the importance of glazing and the need for proper workmanship. Considering all these, this Section was introduced in the third revision of the Code in 2016 as part of the National Building Code of India.

This Section provides guidance in the selection of appropriate glazing for various types for building construction; guidance on the energy and light aspects while choosing glazing; guidance on determining the appropriate thickness of glass used in building glazing and guidance with respect to human impact safety while using glazing in buildings.

Use of organic coated films including safety films on glass shall not classify the glass as safety glass as per this NBCS, and hence users should exercise caution in choosing their options.

Information on installation of glass mirrors and glass railings are given in the informative Annex H and Annex J, respectively.

A conformity assessment sheet for evaluating the compliance of glass and glazing systems with the requirements of this Section has been included in informative Annex K.

This Section was introduced in the Code in 2016 as part of the National Building Code of India. As a result of experience gained in implementation of 2016 version of this Section, feedback received as well as in view of formulation of new standards in the field of glass and glazing and revision of some existing standards, a need to revise this Section was felt. This revision was, therefore, prepared to take care of these aspects.

In this revision, this publication has been renamed as National Building Construction Standards (NBCS).

The significant changes incorporated in this revision include:

a) Definitions of various existing terms have been reviewed and updated, wherever required;

b) Provisions related to the requirements for laminated safety glass, toughened (tempered) safety glass and heat strengthened glass in **4** have been updated;

c) Clause **5** on energy and light has been reviewed and updated, and new provisions on energy design considerations and window design guidelines for non-conditioned/mixed mode buildings have been included;

d) The types of glass permitted for fire-resistant glazing within the scope of the Section in **6** have been updated;

e) Inclusion of provisions for determining the fire resistance performance of perimeter fire barrier joint systems, thereby enhancing fire safety measures;

f) New provisions addressing anti-fallout features, window restrictors for child safety, and dynamic wind restraint mechanisms, have been included in **7.2**, **7.3** and **7.4** respectively;

g) A new clause **9** on security glass has been introduced, covering glass for security applications such as bullet resistance, burglary resistance, and blast resistance;

j) Incorporation of provisions for assessing curtain walls and storefront systems under inter-storey drift conditions in Annex A;

h) Provisions related to railings with glass infill panels and free-standing glass protective railings have been modified in Annex J;

k) Addition of a conformity assessment sheet to evaluate the compliance of glass and glazing systems with the requirements outlined in this Section in Annex K; and

m) References to all the concerned Indian Standards have been updated.

The information contained in this Section is largely based on the following Indian Standards:

IS No.	*Title*
IS 16231	Use of glass in buildings — Code of practice:
(Part 1) : 2019	General methodology for selection (*first revision*)
(Part 2) : 2019	Energy and light (*first revision*)
(Part 3) : 2019	Fire and loading (*first revision*)
(Part 4) : 2019	Safety related to human impact (*first revision*)

Assistance has also been derived from the following publications in the formulation of this Section:

ISO 9845-1 : 2022	Solar energy — Reference solar spectral irradiance at the ground at different receiving conditions — Part 1: Direct normal and hemispherical solar irradiance for air mass 1,5
ISO 10291 : 1994	Glass in building — Determination of steady-state U values (thermal transmittance) of multiple glazing — Guarded hot plate method
ISO 10292 : 1994	Glass in building — Calculation of steady-state U values (thermal transmittance) of multiple glazing
ISO 10293 : 1997	Glass in building — Determination of steady-state U values (thermal transmittance) of multiple glazing — Heat flow metre method

All standards, whether given herein above or cross-referred to in the main text of this Section, are subject to revision. The parties to agreement based on this Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

As the regulation of land development and buildings is a State subject and is dealt by the States and local bodies such as urban local bodies within their jurisdiction through building regulatory documents like building regulations, building byelaws, and fire regulations, this document is voluntary in nature and is non-binding. The implementation depends on adoption by concerned parties or stipulations in a contract or by appropriate adoption by the concerned authorities.

For the purpose of deciding whether a particular requirement of this Section is complied with, the final value, observed or calculated, expressing the result of a test or analysis, shall be rounded off in accordance with in the rounded off value should be the same as that of the specified value in this Section.

This Page has been Intentionally left blank

Important Explanatory Note for Users of this NBCS

In any Part/Section of this NBCS, where reference is made to **'good practice'** in relation to design, constructional procedures or other related information, and where reference is made to **"accepted standard"** in relation to material specification, testing, or other related information, the Indian Standards listed at the end of the Part/Section shall be used as a guide to the interpretation.

At the time of publication, the editions indicated in the standards were valid. All standards are subject to revision and parties to agreements based on any Part/ Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

In the list of standards given at the end of a Part/Section, the number appearing within parentheses in the first column indicates the number of the reference of the standard in the Part/Section. For example:

a) Accepted standards [C-8(1)] refers to the Indian Standards given at serial number (1) of the list of standards given at the end of this Part C/Section 8, that is, IS 14900 : 2018 'Specification for transparent float glass (*first revision*)' and IS 2553 (Part 1) : 2018 'Specification for safety glass: Part 1 Architectural, building and general uses' (*fourth revision*).

NATIONAL BUILDING CONSTRUCTION STANDARDS

PART C STRUCTURAL DESIGN

SECTION 8 GLASS AND GLAZING

1 SCOPE

1.1 This NBCS (Part C/Section 8) covers,

a) selection and application of glass in buildings, different types of glass, their requirements and associated glazing materials;

b) guiding provision for glazing in buildings with respect to their effect on energy, visual (light) and solar environments in the building;

c) selection of glass in buildings, subject to wind loading, seismic loading and special considerations for fire rated glass and related materials;

d) provisions for the selection and manifestation of glass in buildings, subject to safety with respect to human impact of the occupants;

e) provisions relating to glazing systems such as selection, design, fabrication, installation, testing and maintenance; and

f) requirement and selection criteria for security glass in buildings.

1.2 This Section does not cover patent glazing.

NOTE — The provision of this Section pertains to glass and installation thereof. However, parties, as per their mutual agreement, may appropriately utilize the relevant provisions for installation of alternative sheeting materials used for similar purposes such as plastic glazing sheets/polycarbonate sheets taking also into account requirements of safety issues as applicable with the specific material.

1.3 The provisions in respect of sustainable use of glass in buildings are covered in relevant guidelines/best practices (Handbook on 'Sustainability in Buildings').

2 TERMINOLOGY

For the purpose of this Section, the following definitions shall apply, and for other terms those given in accepted standards [C-8(1)] shall apply.

2.1 Annealed Glass (*see* **Glass**) — Also known as 'normal' glass, which has not been subjected to toughening, lamination and heat strengthening. It is the product obtained from the process of slow and steady cooling of hot glass in order to relieve internal stresses or thermal induced stresses.

NOTE — This term is most commonly used for flat glass.

2.2 Annealed Fire Resistant Glass — Type of glass which is made out of annealed glass combination and is tested for the required duration and satisfies the intended criteria of fire resistance. These types of glasses may not possess the best of the impact resistance characteristics and may be used as vision panels.

2.3 As-Cut Finished Sizes — Finished panes of flat glass cut from stock/standard sizes. They may be subject to further processing, such as edge working, drilling, face decoration, etc.

2.4 Aspect Ratio — The ratio of a longer side of glass pane to its shorter side.

2.5 Balustrade — A low barrier forming a parapet to a stair, ramp, balcony, raised level or a change in level.

2.6 Beads or Glazing Beads — A strip of wood, metal or other suitable material attached to the rebate to retain the glass in position in the frame.

2.7 Bite — The minimum distance by which the inner edge of a frame (or a stop) overlaps the edge of the glass panel.

2.7.1 *Glazing Bite* — The dimension by which the framing system overlaps the edge of the glazing infill. Minimum glazing bite shall be 10 mm for non-structural sealant applications.

2.8 Block (Setting Block) — A small piece of wood, plastic, rubber or other suitable material used between the edges of the glass (generally the bottom edge only) to centralize the glass in the frame (frequently called a setting block).

2.9 Chair Rail — A fixed rigid bar that provides protection from human impact.

2.10 Clear Glass — A transparent glass with neutral/near colourless appearance.

2.11 Coefficient of Linear Expansion — It is expressed as the strain (change in length per unit length) per unit variation of temperature of a material.

2.12 Combustible Material — The material which when burnt adds heat to a fire when tested for combustibility in accordance with accepted standard [C-8(2)].

2.13 Corridor — A common passage or circulation space including a common hall.

2.14 Coupled Glazing (also known as Secondary Glazing) — Two panes of glazing spaced apart in an opening, either in the frame or glazed separately, to form an unsealed cavity.

2.15 Curtain Wall — Non-load bearing structure/partition of glass attached to the building frame, usually on the exterior face. Curtain wall vertical framing members run past the face of floor slabs, and provision for anchorage is typically made at vertical framing members only.

NOTE — In contrast to combination assemblies and composite units, curtain wall systems often need to meet additional performance requirements for inter-storey differential movement, seismic drift (*see* Annex A), dynamic water infiltration, etc. Operating vents and entrance doors are provided as separate inserts.

2.16 Curtain Wall Assembly — A fire rated or non-fire rated, non-load bearing exterior wall assembly secured to the structural members of the building.

2.17 Distance Piece — A small piece of wood or other suitable material used to locate the glass between the bead and the back of the rebate to prevent lateral movement.

2.18 Door or Shutter Assembly Door-Set — A pedestrian door-set or industrial type door-set including any frame or guide, door leaf or leaves, rolling or folding curtain, etc, which is provided to give a fire resisting capability when used for the closing of permanent openings in fire resisting separating elements, which includes any side panel(s), vision panel(s), flush over panel(s) and/or transom panel(s) together with the building hardware and any seals (whether provided for the purpose of fire resistance or smoke control or for other purposes such as draught or acoustics) which form the assembly.

2.19 Double Glazed Fire Resistant Glass — A fire resistant glass that is used in a double glazed unit.

NOTE — These shall be tested as a complete Double Glazed Unit (DGU) or other multiple glazed units as the case may be. Double glazed fire resistant glass can be a combination of intumescent laminated fire rated or tempered fire resistant glass. Fire resistant glass cannot be combined with another glass and used as a DGU unless the combined double glazed or multiple glazed units are also tested.

2.20 Double Glazing — Glazing formed by an assembly of two glass panes separated by a spacer and the gap may be filled by vacuum, air or inert gases and hermetically sealed along the periphery to improve the thermal insulation.

2.21 Edge Deterioration — The discolouration of the reflective coating at the edge of the silvered glass.

2.22 Edge Faults — The faults that affect the as-cut edge of the glass. They may include entrant/emergent faults, shelling, corners on/off and vents.

2.23 Edge Polished — It is usually applied to flat glass, the edges of which have been polished after cutting.

2.24 Edging — Grinding the edge of flat glass, to a desired shape or size.

2.25 Exposed Edge — A glass panes' edge that is not covered.

2.26 Facade — It is the front or face of the building which is part of framed or frameless system.

2.27 Faceted Glazing — It is a type of glazing in which flat panes of glass are installed vertically at an angle to each other to form a faceted surface.

2.28 Fenestration — All area (including frame) in the building envelope that let in light, including window, plastic panels, clerestories, skylight, fanlight and glass doors that are generally more than one-half the floor height, and glass block walls.

2.29 Fin — A piece of glass positioned and fastened to provide lateral support.

2.30 Fire Separation — The shortest distance, in metre, measured from the external wall of the building concerned to the external wall of any other building on the site, or from other site, or from the opposite side of street or other public space for the purpose of preventing the spread of fire.

2.31 Float Glass — Flat, transparent, clear or tinted soda-lime silicate glass having parallel and polished surfaces obtained by continuous casting and floatation on a metal bath.

NOTE — Flat glass is a general term covering sheet glass, float glass and various forms of rolled and plate glass in which shape of the glass is flat and commonly used for windows, glass doors, transparent walls and other architectural applications.

2.32 Flush Over Panel — A panel which is incorporated within a door-set or openable window and fitted above the leaf or leaves within the frame head and the jambs and with no transom.

2.33 Frame — An element made of timber/metal/aluminium or other durable material/combinations of materials, such as glass fins and structural sealant, supporting the full length of a glazed panel edge.

2.34 Frameless Glazing — An unframed glazing which maintains the integrity through pointed support structures.

2.35 Front Putty — The compound forming a triangular fillet between the surface of the glass and the front edge of the rebate.

2.36 Fully Framed Glazing — The glazing whose panels have all its four edges framed.

2.37 Gap — A clearance between two adjacent surfaces and/or edges, for example between the edge of the leaf and the reveal of the frame or between the face of the leaf and the frame stop.

2.38 Glass — An inorganic product of fusion which has cooled to a rigid condition without crystallizing. It is typically hard and brittle, and has a conchoidal fracture. It may be colourless or tinted and transparent to opaque. The term glass refers to monolithic glass unless specified otherwise.

2.39 Glass Appearance Faults — Faults such as spot and/or linear and/or enlarged area faults which alter the visual quality of glass.

2.40 Glazing — Act of securing of glass or other glazing material into a building in prepared openings in windows, door panels, partitions, etc.

2.41 Guard Rail — A permanent physical barricade used to prevent human impact on glass/glazing.

2.42 Hairline Scratch — Very fine scratch that can hardly be seen with naked eye and is associated with glass cleaning techniques.

2.43 Halo — It is the distortion zone around a spot fault.

2.44 Heat Soaking — It is done on toughened/tempered glass by reheating to a temperature of 290 ºC and keeping it at this temperature for 8 h and cooling it gradually. The glass can break spontaneously and without provocation due to possible impurity of nickel sulphide in basic glass used for toughening/tempering. This risk of spontaneous breakage can be minimised by heat soaking process by forcing such glasses to break during the test itself.

2.45 Heat Strengthened Glass — A single piece of glass within which a permanent surface compressive stress, additionally to the basic mechanical strength, has been induced by a controlled heating and cooling process in order to give it increased resistance to mechanical and thermal stress and prescribed fracture characteristics {*see* **6.1.5** of accepted standard [C-8(3)]}.

2.46 Hermetic Seal — A complete seal (especially against the escape or entry of air which is impervious to outside interference or influence) done on insulating glass units.

2.47 High Activity Area — An area where multiple and major human activity takes place.

2.48 High Risk Area — An area prone to human injury and casualty.

2.49 Infill Balustrades — The balustrades in which the supported glass resists an infill pressure and/or point load applied to the glass panel.

2.50 Insulating Glass Unit (IGU) — An assembly consisting of at least two panes of glass, separated by one or more spaces, hermetically sealed along the periphery, mechanically stable and durable.

2.51 Interlayer — Layer or material acting as an adhesive and separator between plies of glass and/or plastic glazing sheets.

NOTE — It can be designed to give additional performance to the finished product, for example impact resistance, fire resistance, solar control and acoustic insulation.

2.52 Internal Partition — An interior dividing wall or such portion of an interior dividing wall that is not a door, side panel, shop front or atrium wall.

2.53 Light Transmission — It is the measure of light passing through a transparent or a translucent material.

2.54 Light Transmittance — It is the measure of percent of visible light transmitted through glass pane which depends on type of body substrate and coating done on glass.

2.55 Linear Defects — They are the scratches and extended spot faults on the glass.

2.56 Manifestation — Any technique for enhancing a person's awareness of the presence of transparent glass.

2.57 Maximum Thickness — The thickness of a pane of glass at the maximum thickness tolerance.

2.58 Minimum Thickness — The thickness of a pane of glass at the minimum thickness tolerance.

2.59 Modulus of Elasticity (Young's Modulus) — This modulus expresses the tensile force that theoretically has to be applied to a glass specimen to stretch it by an amount equal to its original length. It is expressed as a force per unit area (for glass, $E = 0.7 \times 10^5$ N/mm^2 = 70 GPa).

2.60 Monolithic Glass — A single sheet of flat glass which could be either annealed, toughened or heat strengthened.

2.61 Mullion — Vertical framing member supporting the edge or surface of the glass. It is responsible for transferring loads to the sub-structure.

2.62 Nominal Thickness — A numeric designation that indicates the approximate thickness of glass.

2.63 Non-Combustible Material — A material not liable to burn itself or to add heat to a fire when tested for combustibility in accordance with good practice [C-8(2)].

2.64 Organic Coated Glass — A sheet of glass coated on one or both sides with an applied organic coating or sheeting.

2.65 Pane — A single piece of glass or plastic glazing sheet material in a finished size ready for glazing.

2.66 Panel — An assembly containing one or more panes of glass.

2.67 Partition — It means an interior non-load bearing divider, one storey in height or part.

2.68 Partly Framed or Unframed Glazing — The panels that have one or more edges unframed.

2.69 Passive Solar Gain — The solar radiation in the form of energy and light which is transmitted through the glazing into the building and which can be utilized as a source of energy to reduce the need for artificial lighting.

2.70 Patterned Glass — A rolled glass having a distinct pattern on one or both surfaces.

2.71 Perimeter Fire Barrier — The perimeter joint protection that provides resistance to prevent the passage of fire and/or smoke from floor to floor within the building at the opening between the exterior wall assembly and the floor assembly (*see also* **6.4.3.7**).

2.72 Protective Coating(s) Faults — The faults where the metallic layer is exposed. They can be scratches or loss of adhesion of the protective coating(s).

2.73 Rebate — The part of a surround; the cross-section of which forms an angle into which the edge of the glass is received.

2.74 Reflective Coated Glass — It is a glass with reflective coating which uses the principle of increasing the direct reflection to maximize solar energy attenuation. In comparison with clear glass, its absorption of solar energy is also increased.

NOTE — In comparison with float glass surface, these reflecting coatings (due to their composition) exhibit lower level of emissivity which improves their *U*-value.

2.75 Reflective Silver Coating Faults — It is the fault on reflective silver layer which shall alter the appearance of the silvered glass. They consist of scratches, stains, colour spots and edge deteriorations.

2.76 Residual Protection — It is the protection provided to avoid the human impact on glass. It is provided on the side of glass where there are chances of human impact. It can be achieved by providing a sill structure or a grill inside.

2.77 Safety Glass

2.77.1 *Laminated Safety Glass* — Two or more pieces of glass held together by an interleaving layer or layers of plastic sheet material. The laminated safety glass will crack and break under sufficient impact, but the pieces of glass tend to adhere to the plastic and do not fly.

NOTE — The railing and overhead glazing shall consist exclusively of laminated safety glass.

2.77.2 *Toughened* (*Tempered*) *Safety Glass* — A single piece of specially heat treated glass, with a stress pattern such that the piece when fractured reduces to numerous granular fragments, with no large jagged edges.

2.78 Shading Coefficient — The ratio of the rate of solar heat gain through a specific unit assembly of glass to the solar heat gain through a single light of 3 mm clear glass in the same environment.

2.79 Sheet Glass — Glass made in large sheet directly from furnace or by making a cylinder and then flattening it.

NOTE — These transparent glass have a glossy, fire-finished, apparently plane and smooth surfaces, but having a characteristic waviness of surface.

2.80 Skylight — A fenestration surface having a slope of less than 60º from the horizontal plane. Other fenestration, even if mounted on roof of a building is considered as either a vertical glazing or sloped glazing depending upon the angle of the glazing.

2.81 Sloped Overhead Glazing — A glazing that is inclined at less than 75º to the horizontal and located, wholly or partially, directly above an area that may be used by people.

2.82 Solar Energy Absorption — The percentage of the solar spectrum energy (ultraviolet, visible, and near-infrared) from 300 nm to 2 500 nm that is absorbed by a glass product.

2.83 Solar Energy Transmittance (Direct) — The percentage of energy in the solar spectrum, ultraviolet, visible, and near-infrared energy, 300 nm to 2 500 nm, that is directly transmitted through the glass.

2.84 Solar Heat Gain Coefficient (SHGC) — The SHGC is the fraction of incident solar radiation admitted through a fenestration, both directly transmitted, and absorbed and subsequently released inward through conduction, convection and radiation.

2.85 Spandrel — A non-vision portion of the exterior wall of a building.

2.86 Spot Faults — The nuclei (solid or gaseous inclusions), deposits, crush marks, etc, in the glass. In certain instances, spot faults are accompanied by a distortion zone called 'halo'. The nucleus of the spot fault is measurable.

2.87 Stain — An alteration of the reflective coating characterized by a more or less brownish, yellowish or greyish colouration of zones which can sometimes cover the whole reflective surface.

2.88 Stock/Standard Sizes — The panes of flat glass such as coated, mirror, enamelled glass, etc supplied with as-cut edges which are intended for further processing. These are generally corresponded with manufacturer’s production size.

2.89 Tempered Fire Resistant Glass — A single piece of specially thermally-treated or chemically treated glass, tested for fire resistance for the required duration and having such a stress pattern that the piece when fractured, reduces to numerous granular fragments, with no large jagged edges.

2.90 Test Assembly — The complete assembly of the test specimen together with the test apparatus.

2.91 Thermal Transmittance (*U*) — Thermal transmission through unit area of the given building unit divided by the temperature difference between the air or other fluid on either side of the building unit in steady state conditions. It is also called as *U*-value. Its unit is W/m^{2}K.

NOTES

1 Thermal transmittance differs from thermal conductance insofar as temperatures are measured on the two surfaces of a building unit in the latter case and in the surrounding air (or other fluid) of the material on the two sides, in the former case. Thermal conductance is a characteristic of the building unit whereas thermal transmittance depends on conductance and surface coefficients of the building unit under the conditions of use.

2 In the case of glazing, thermal transmission is taken through the central part of the glazing, that is, without edge effects.

2.92 Through Component/Connection — The internal spacer or fixing that either penetrates through the door-set or openable window from one face to another or directly connects the faces of one to the other.

2.93 Tinted Glass — A normal flat glass to which colourants (normally metal oxides) are added during manufacturing process to achieve tinting and solar radiation absorption properties. It is also referred to as body tinted glass {*see* accepted standard [C-8(4)]}.

2.94 Transom — A horizontal cross bar connecting two vertical members in a glazing frame.

2.95 Unframed Glazing — A glazing with one or more edges unframed.

2.96 UV Transmittance — The percentage of energy in the ultraviolet (UV) spectrum from 300 nm to 380 nm that is directly transmitted through the glass.

2.97 Vertical Fenestration — All fenestration other than skylights. Trombe wall assemblies, where glazing is installed within 300 mm of a mass wall are considered walls and not fenestration.

2.98 Wired Glass — It is a type of glass into which a wire mesh is embedded during production. Wired glass has an impact resistance similar to that of normal glass, but in case of breakage, the mesh retains the pieces of glass.

3 APPLICATION

The type of glass chosen shall satisfy the following criteria:

a) For a given application, the type and thickness of glass selected shall be in accordance with the requirements provided herein and the thickness calculation as subjected to wind load shall also satisfy requirements for human impact safety;

b) Installation of glass to the building is done in accordance with the various provisions available in this Section and in the absence of any specific provisions the same shall be as per manufacturer's instructions;

c) Optical, solar, thermal performance of glazing (clear/tinted/coated reflective glass) shall have the characteristic performances, such as:

    1) spectral transmittance, external and internal spectral reflectance;
    2) light transmittance, external and internal light reflectance;
    3) solar direct transmittance and reflectance;
    4) UV transmittance; and
    5) better thermal transmittance (*U*-value).

4 GENERAL METHODOLOGY FOR SELECTION

4.1 Selection

4.1.1 Right from the initial project evaluation stage, a suitable methodology that incorporates the implications of use of glass materials and their influence on performance of the building shall have to be looked into. A typical flowchart outlining such a methodology is provided (*see* Fig. 1).

It is assumed that,

a) the location of area to be glazed and its preliminary size/shape have been decided as part of normal building design process,

b) the designer has gained information on glass/and plastic glazing sheet materials used in similar circumstances, and

c) the designer is cognizant of implications of any innovation in design.

CONFIRM PRELIMINARY SELECTION OR PERFORM REQUIRED MODIFICATIONS BEFORE REVIEWING
FINALIZE THE DESIGN

FIG. 1 TYPICAL SEQUENCE OF DESIGN EVALUATION FOR GLAZED AREAS

4.1.2 Design requirement including aesthetic considerations and client specified requirements such as security and maintenance are to be considered.

4.1.3 Effect of design on cost such as initial cost of glazing (specification of glass/plastic sheeting material; glazing method; access for initial glazing; work schedule; protection during construction); effect of glass/plastic sheeting material on capital/running cost related to building heating/cooling, lighting and ventilation; and maintenance cost of glazed areas (access for cleaning and reglazing) should be considered.

4.1.4 Selection of appropriate glass may be done considering the cost benefit analysis in respect of the benefit accrued against the alternatives available. Also, the comparative cost of glazing materials should be considered together with their life expectancy and probability of need for maintenance. In the context of selection of glass, the provisions given in the relevant guidelines/best practices (Handbook on 'Sustainability in Buildings') may also be considered in addition to the cost benefit analysis on the use of glass *vis-a-vis* use of other alternatives.

4.2 Types of Glass

4.2.1 The soda lime silicate glass is classified based on the type of internal stress which determines the strength of the glazing towards breakage, design and installation procedure and based on application. Table 1 gives the typical properties of various types of glass.

4.2.2 *Normal* (*Annealed*) *Glass*

Normal (Annealed) glass shall be as per accepted standard [C-8(5)] for flat transparent sheet glass or as per accepted standard [C-8(6)] for transparent float glass.

4.2.3 *Laminated Safety Glass*

Two or more pieces of glass held together by an interleaving layer or layers of plastic sheet material. The laminated safety glass will crack and break under sufficient impact, but the pieces of glass tend to adhere to the plastic and do not fly. For requirements of laminated safety glass, accepted standard [C-8(7)] shall be referred.

Table 1 Typical Properties of Various Types of Glass

(*Clause* 4.2.1)

Sl No. (1)	**Properties** (2)	**Annealed Glass** (3)	**Float Glass** (4)	**Annealed Laminated Glass** (5)	**Tempered or Toughened Glass** (6)
i)	Modulus of rupture	40 N/mm^2	40 N/mm^2	40 N/mm^2	120 N/mm^2 to 200 N/mm^2
ii)	Thickness	As per accepted standard [C-8(5)]	As per accepted standard [C-8(6)]	6.38 mm to 19 mm	3 mm to 19 mm
iii)	Density (approximate)	← 2 400 kg/m^3 to 2 550 kg/m^3 →			
iv)	Modulus of elasticity	← 70 GPa →			
v)	Coefficient of linear expansion	← 9×10^{-6} m/m K →			
vi)	Compressive strength	← 1 000 N/mm^2 →			

NOTE — Conventionally, the following types of glass exist:

a) Annealed (clear) glass;
b) Extra clear glass;
c) Body tinted glass;
d) Coated glass (including Lacquered glass); and
    1) Online coated glass; and
    2) Offline coated glass.
e) Processed glass — Each of the glasses (a) to (e) above can be subjected to further processing to produce the following types:
    1) Heat strengthened;
    2) Toughened or tempered;
    3) Double glazed unit;
    4) Laminated glass (single laminated);
    5) Laminated double glass unit;
    6) Ceramic/screen printed fritted glass (patterned glass); and
    7) Fire safety glass.

4.2.4 *Toughened* (*Tempered*) *Safety Glass*

A single piece of specially heat treated glass, with a stress pattern such that the piece when fractured reduces to numerous granular fragments, with no large jagged edges. For requirements of toughened safety glass, accepted standard [C-8(7)] shall be referred.

4.2.5 *Heat Strengthened Glass*

A single piece of glass within which a permanent surface compressive stress, additionally to the basic mechanical strength, has been induced by a controlled heating and cooling process in order to give it increased resistance to mechanical and thermal stress and prescribed fracture characteristics {*see* **6.1.5** of accepted standard [C-8(3)]}. Heat strengthened glass shall have a surface compression between 31 MPa and 52 MPa (4 500 and 7 500 psi) when tested as prescribed in **6.5** of accepted standard [C-8(3)]. For requirements of heat strengthened glass, accepted standard [C-8(8)] shall be referred.

NOTE — Heat strengthened glass is not a safety glass.

4.2.6 *Coated Glass*

A metallic coating is applied to one side of the glass in order to significantly increase the amount of reflection by the glass of both the visible and infrared (light and heat) ranges of the electromagnetic spectrum. This metallic coating can be applied to clear or body tinted glass, without adversely affecting the transparency of the glass. The reflective glass imparts an enhanced appearance to the exterior of buildings due to the coating of metal oxides on the glass. It is widely applied as an aesthetic and energy efficient product in buildings for its highly reflective surface and wide palette of colours. It reduces heat gain and glare from the exterior and allows optimum visible light transmission to the interior. If designed/used properly, reflective glass can aid in reducing the air conditioning load of buildings.

NOTE — Highly reflective glass should be avoided, especially in internal environments. The reflections from these surfaces can be particularly confusing for persons with vision impairment.

4.2.7 *Insulating Glazing Unit*

Insulating glazing units are two or more panels of glass spaced apart and hermetically sealed to form a single unit with air or inert gas filled space between the panels. The spacer is made of aluminium that is either mill-finished or painted/anodized in different colours or finishes, or an equivalent alternative material. Desiccants are filled inside the spacer framework to prevent condensation inside the unit. The primary sealant acts as a barrier to moisture and vapour penetration. The secondary sealant provides structural integrity to the unit. For requirements of insulating glazing unit, accepted standard [C-8(9)] shall be referred.

NOTE — Moisture penetration test and argon/krypton gas level test are typically carried out to determine the characteristic of IGUs.

4.2.8 *Rolled Glass — Patterned*, *Extra Clear Patterned*, *Wired and Wired-Patterned Glass*

The general requirements including thickness, dimensional tolerance and tests for wired glass as specified in accepted standard [C-8(10)] are valid.

4.2.9 *Glass Fins*

When glass fins are used as a decorative member, it can be either toughened (tempered) or laminated glass.

When glass fins are used as a structural member, it shall be toughened and laminated. The depth and thickness may vary as per elevation and wind load requirements. Design should also accommodate movements and verified for lateral torsional buckling. It is recommended to use finite element analysis to determine the appropriate glass fin sizes.

4.3 Application

Glass can be designed/suited to use in building occupancies such as in residential, assembly and mercantile in elements such as facades, windows, doors, partitions, display units, shop fronts, greenhouses (where plants are grown) and atrium. Different types of glass are selected based on requirements. For safety against accidental breakage and strength requirement (mechanical and thermal), toughened glass or laminated glass may be considered over annealed glass. For increased high security requirements, acoustic insulation, sloped glazing and skylights, laminated glass may be considered.

4.4 Associated Glazing Materials

4.4.1 *Structural Sealant*

The structural sealant could be of silicone type with requirements meeting the design criteria. Structural sealant shall be shelf-stable, natural-cured, elastomeric adhesive exhibiting the desired adhesion to building substrates. The structural sealant may require cleaning and/or priming to get good adhesion for structural glazing application. For laminated glass applications where glass edges are sealed with a sealant, compatibility shall be ensured with the interlayer to avoid delamination.

Structural sealant shall be as per accepted standard [C-8(11)].

4.4.2 *Gaskets*

Gasket is a mechanical seal that fills the space between two mating surfaces, to prevent leakage from or into the joined objects and will be able to deform while under compression and tightly fills the space it is designed for, including any slight irregularities. Gaskets shall be as per **5.10** of accepted standard [C-8(12)].

4.4.3 *Preformed Tape*

Typical requirements of preformed butyl and foam tapes shall be as given in Table 2.

4.4.4 *Setting Blocks, Location Blocks and Distance Pieces*

Setting blocks, location blocks, and distance pieces shall be designed in accordance with **6** which are:

a) resilient, load-bearing, non-absorbent and rot-proof materials; and

b) compatible with all other materials that may come in contact with them.

4.5 General Requirements

4.5.1 Glazing and associated materials used for the proper installation shall satisfy the minimum dimensional and framing requirements in accordance with the procedures given in this Section. The dimensional and thickness tolerance of the glass used in exterior and interior is determined from the provisions given hereunder.

4.5.2 *Dimensional Requirement*

4.5.2.1 The dimensions for edge clearance, edge cover, and front and back clearance, as defined in Fig. 2, shall be not less than the values given in Table 3.

NOTE — For glazing systems where the framing member is aluminium or steel and gaskets are used to capture the glazing, minimum glazing bite of 12.7 mm is recommended for architectural glazing.

4.5.2.2 *Front putty width*

The front putty width shall be not less than 10 mm for panels up to 1 m^2, and not less than 12 mm for panels between 1 m^2 and 2 m^2.

Table 2 Typical Properties of Preformed Tapes

(*Clause* 4.4.3)

Sl No. (1)	Properties (2)	Requirement (3)
i)	Low temperature flex	No cracks at – 23 °C
ii)	Weight loss	2 percent, *Max*
iii)	Vehicle migration	1 paper stained maximum and this stain shall be no more than 3.2 mm from edge of sample maximum

Table 2 (*Concluded*)

Table 2 Typical Properties of Preformed Tapes

(*Clause* 4.4.3)

Sl No. (1)	Properties (2)	Requirement (3)
iv)	Backing removal	No transfer of tape compound to the paper
v)	Yield strength	41.4 kPa, *Min*
vi)	Compression/Recovery	Compression index, 1.22 N/mm^2, *Max*
vii)	Water absorption	Weight gain maximum after boiling, 40 kg/m^3
viii)	Flow test	Loss of height, 60 percent, *Max*

FIG. 2 SIZES AND REBATES

4.5.2.3 *Dimensions of rebates and grooves* (*width and depth*)

Dimensions of rebates and grooves shall accommodate the requirements of Table 3 and allow for the appropriate setting and location blocks (*see* **6**).

4.5.2.4 *Glass dimensional tolerance*

The tolerance for dimensions shall be as per those in the respective Indian Standards.

4.6 Frame Requirements

4.6.1 When completely assembled and glazed, the secondary design action effects due to deflection of the frame member supporting the edge of the glass shall be allowed for.

4.6.2 *Deflection Limits*

The frame deflection limits under serviceability loading shall satisfy the conditions for four sided frames as given in **6.3.6.2**(c).

NOTE — In framing members, where reinforcement/fixing brackets are required to meet the deflection/stress criteria, it may be of aluminium or steel. When steel is used, proper dielectric galvanic separation shall be used. The material chosen for reinforcement shall be in close proximity in the galvanic series, to ensure dielectric separation.

4.6.3 *Panels Glazed into the Building Structure*

A panel glazed directly into a building structure by means of appropriate beads or stops shall be considered to be framed, provided the assembly complies with the deflection requirements of **4.6.2**.

4.6.4 *Mixed Framing*

Glass supported along the top and bottom edges by one means and along the vertical edges by another means shall be considered to be framed provided each frame member of the assembly complies with the deflection requirements of **4.6.2**.

4.7 Glass Dimensions

4.7.1 The actual thickness for each pane of glass shall be measured using screw calliper as per **4.3** of accepted standard [C-8(6)].

The actual thickness of glass, rounded to the nearest 0.1 mm shall not vary from the nominal thickness by more than the tolerances specified in respective Indian Standard or the values provided in this Section (where Indian Standard specifications are not available).

The minimum thickness allowed in insulated glazing unit (IGU) should be the sum of minimum thickness allowed of two panes as per accepted standard [C-8(6)] plus thickness of air-gap.

As per the accepted standard [C-8(7)], the nominal thickness of laminated safety glass shall be the sum of the nominal thickness of constituent panes of glass and interlayer material. The limit deviation of the interlayer shall not be taken into account if the total interlayer thickness is < 2 mm.

If the total interlayer thickness is > 2mm, a limit deviation of ± 0.2 mm shall apply. For plastic glazing sheet material, the limit of deviation on thickness shall be the same as applicable to a float glass of the same nominal thickness.

The limit deviations on thickness of laminated glass shall not exceed the sum of the limit deviations of the constituent glass panes as specified in accepted standard [C-8(6)].

NOTES

1 Type A applies to linseed oil and metal casement putties.

2 Type B applies to non-setting glazing compounds, plastic glazing compounds, two-part rubberizing compounds, sealants and preformed strip materials.

3 Type C applies to gaskets made from extruded materials such as butyl strip, PVC, neoprene and sanoprene held in position by pressure upon the glass.

4 For non-standard glass thicknesses the nearest values of nominal thickness, shall be used.

5 Timber and PVC frames may not require the specified front and back clearances provided the waterproofing performance requirements are met.

6 The dimensions are the minimum necessary for the structural integrity of glass only but do not apply to insulating glass units.

4.7.2 Length and width are defined with reference to the direction of draw of the flat glass ribbon (*see* Fig. 3).

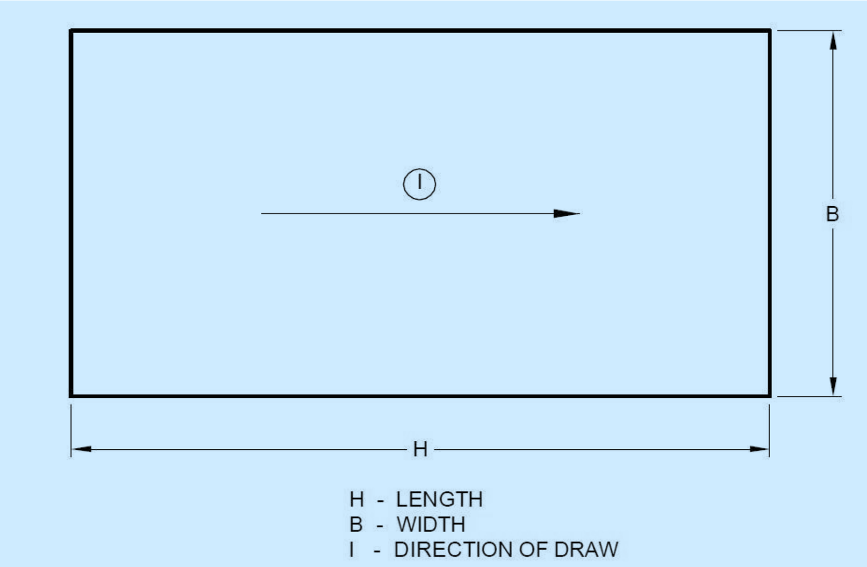

FIG. 3 REPRESENTATION OF LENGTH, WIDTH AND DIRECTION OF DRAW

4.7.3 *Jumbo Sizes*

Glass is available commonly in the following sizes, nominal length (H) 4 500 mm to 6 000 mm and nominal width, (B) 3 660 mm or 3 210 mm.

NOTE — The usual width is 3 660 mm or 3 210 mm. Other sizes may be mutually agreed to between the manufacturer and the user based on their requirement.

4.7.4 *Stock Size*

Glass is available commonly in the following sizes, nominal length (H) 2 250 mm or 2 440 mm and nominal width, (B) 3 660 mm or 3 210 mm.

NOTE — Maximum glass size available from manufacturer are one consideration, the processing equipment limitation, capabilities of contract fabricator to install unit, availability of specialized transport and handling equipment to deliver unit should be checked in addition.

4.7.5 *Split Sizes*

Glass is delivered in equal or unequal split sizes from the jumbo or stock size.

4.7.6 *Squareness*

For given the nominal dimensions for length (H) and width (B), the pane shall not be larger than a prescribed rectangle resulting from the nominal dimensions increased by the permissible plus tolerance or smaller than the prescribed rectangle reduced by the permissible minus tolerance.

The sides of the prescribed rectangles (*see* Fig. 4) shall be parallel to one another and these rectangles shall have a common centre. For stock/standard sizes the tolerances on nominal dimensions length (H) and width (B), are ± 5 mm.

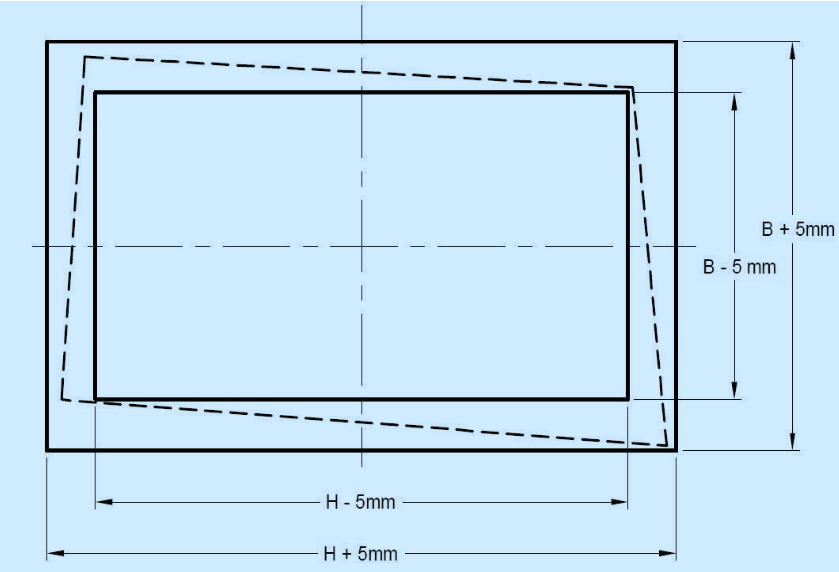

FIG. 4 DETERMINATION OF LENGTH, WIDTH AND SQUARENESS FOR STOCK/SQUARENESS DIRECTION OF DRAW

4.7.7 *As-Cut Finished Size*

The nominal dimension for width and length being given, the finished pane or as-cut finished size shall not be greater than the prescribed rectangle from the nominal dimension increased by the tolerance '*t*' or smaller than the prescribed rectangle reduced by the tolerance '*t*'. The sides of the prescribed rectangles are parallel to one another and these shall have a common centre in accordance with Fig. 5. The limits of the squareness are also mentioned. Tolerances shall be as given in respective accepted standards. An indicative list of such accepted standards is provided in Table 4.

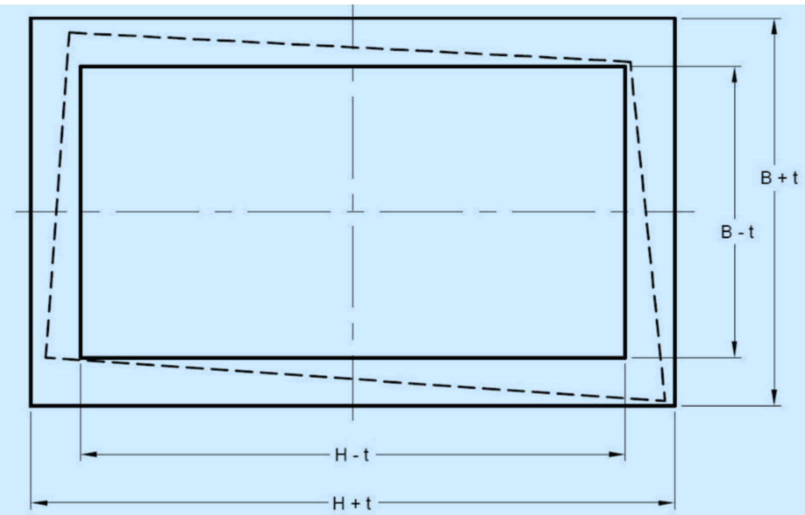

FIG. 5 TOLERANCE (t) FOR WIDTH (B) AND LENGTH (H)

5 ENERGY AND LIGHT

5.1 General

Energy and light performance of glazing system is defined in terms of U-value, solar heat gain coefficient, visible light transmission, internal and external reflection. The overall performance is determined by the efficiency of glass, frame, shading systems and the air tightness of the system. The performance requirement for glazing system shall be suitably selected. Minimum performance requirement is mentioned in the Annex B.

Specific methods of calculating light and energy factors for glass in buildings are covered here and their characteristic data can serve as a basis for light, heating and ventilation calculations of rooms and can permit comparison between different types of glazing. It is applicable to all flat glass material.

5.2 Thermal Energy Transmission

5.2.1 *General*

Glazed areas in buildings should be designed considering overall energy balance, the effects on thermal comfort of occupants and the cooling and heating energy requirements. Solar energy gain is due to transmission of solar radiant energy through the glass into the building. Solar energy is all at relatively short wavelengths and is controlled by using the glass to absorb or reflect the energy. Energy loss is due to the transfer of energy by conduction, convection and long wavelength radiation. The solar energy gain and loss can be regulated by several factors, for example, incorporating air cavities, including low emissivity glass and use of shading systems. Solar energy gain through glazing systems can be advantageous in cold climates for improving thermal comfort and reducing the heating energy requirements.

5.2.2 *Thermal Comfort*

Energy transmission through glazing can significantly influence occupant comfort by raising or lowering room air temperatures. For example, hot sunny weather can lead to excessive energy gains and energy losses can occur through the glazing during cold weather or at night. Thermal comfort can also be influenced by direct solar radiation through the glazing and/or by radiation exchange between the glazing and the occupants. Appropriate choice of glazing and opaque wall systems is essential to avoid radiant asymmetry related thermal discomfort.

5.2.3 *Solar Energy Gain*

The solar energy transmitted through the glass from the outside environment is the part of solar radiation which is transmitted directly through the glass and the part which is re-emitted from the glass after being absorbed. In warm and hot climates, this heat energy which is transmitted through the glass has to be limited in-order to achieve thermal comfort for the occupants and also to reduce the energy demands of the building. Factors that can influence the amount of solar gain through the glazing include:

a) orientation;

b) glazed area;

c) shading devices, both internal and external; and

d) properties of the glazing.

5.2.4 *Total Solar Energy Transmittance*

Total solar energy transmittance is the proportion of solar radiation at normal incidence transferred through the glazing. It is composed of the direct transmittance (short wave component) and the part of the solar absorptance dissipated inwards by long wave radiation and convection (long wave component). The total solar energy transmission properties of solar control glazing can be described by their shading coefficients and solar heat gain coefficient (SHGC)/solar factor (SF). The shading coefficient is derived by comparing the properties of the solar control glazing with a clear float glass having a total solar energy transmittance of 0.87 (that is clear glass between 3 mm and 4 mm thick).

Solar heat gain coefficient (SHGC)/solar factor (SF) is the measure of amount of heat transfer from outside to inside by direct transmission (short wave radiation) and internal remitted radiation (long wave radiation). The SHGC (*see* Fig. 6) or SF depends on the tint of the substrate and the type of coating that is done on the base glass. The amount of solar energy gained through glass is between 0 and 1. Multiplying the SHGC or SF by 100 gives the percentage of solar energy allowed into the building.

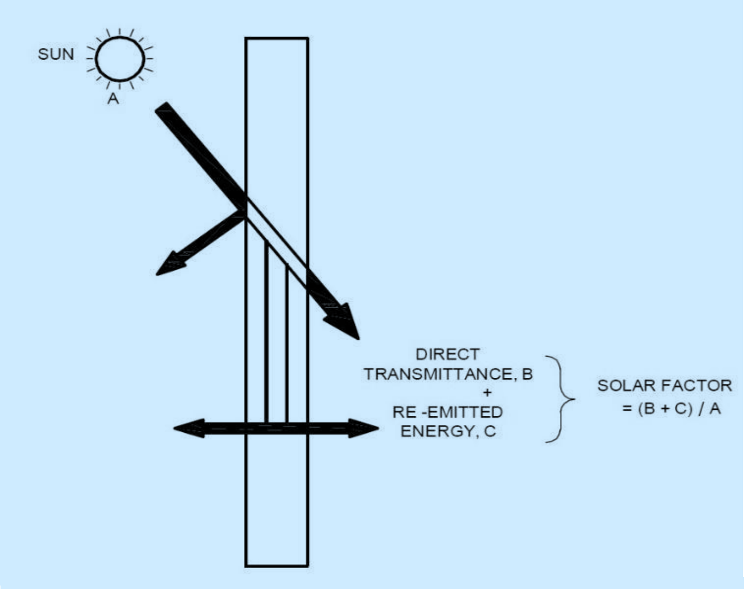

FIG. 6 SOLAR HEAT GAIN COEFFICIENT

The total solar energy transmittance g is the sum of the solar direct transmittance τ_e and the secondary heat transfer factor q_i towards the inside, the latter resulting from heat transfer by convection and long-wave IR-radiation of that part of the incident solar radiation which has been absorbed by the glazing and is expressed as:

$$g = \tau_e + q_i$$

5.2.5 *Division of Incident Solar Radiation Flux*

The incident solar radiant flux per unit area φ_e is divided into the following three parts (*see* Fig. 7):

a) transmitted part, $\tau_e\varphi_e$;

b) reflected part, $\rho_e\varphi_e$; and

c) absorbed part, $\alpha_e\varphi_e$.

where

τ_e = solar direct transmittance;

ρ_e = solar direct reflectance; and

α_e = solar direct absorptances.

τ_e
q_e
q_i

FIG. 7 COMPONENTS OF INCIDENT SOLAR RADIANT FLUX

The relationship between the three characteristics is:

$$\tau_e + \rho_e + \alpha_e = 1$$

The absorbed part $\alpha_e\varphi_e$ is subsequently divided into two parts $q_i\varphi_e$ and $q_e\varphi_e$, which are energy transferred to the inside and outside, respectively:

$$\alpha_e = q_i + q_e$$

where

q_i = secondary heat transfer factor of the glazing towards the inside; and

q_e = secondary heat transfer factor of the glazing towards the outside.

5.2.6 *Solar Direct Transmittance*

The solar direct transmittance τ_e of glazing shall be calculated using the following formula:

$$\tau_e = \frac{\sum_{\lambda=300\text{ nm}}^{2\,500\text{ nm}} \tau(\lambda) S_\lambda \,\Delta\lambda}{\sum_{\lambda=300\text{ nm}}^{2\,500\text{ nm}} S_\lambda \,\Delta\lambda}$$

where

S_λ = relative spectral distribution of the solar radiation;

$\tau(\lambda)$ = spectral transmittance of the glazing; and

$\Delta\lambda$ = integration procedure are the same as in 5.4.5.4 except that the data points shall be chosen at the wavelengths given in Table 5.

5.2.7 *Solar Direct Reflectance*

The solar direct reflectance ρ_e of the glazing shall be calculated using the following formula:

$$\rho_e = \frac{\sum_{\lambda=300\text{ nm}}^{2\,500\text{ nm}} \rho_o\ (\lambda) S_\lambda\ \Delta\lambda}{\sum_{\lambda=300\text{ nm}}^{2\,500\text{ nm}}\ S_\lambda\ \Delta\lambda}$$

where

S_λ = relative spectral distribution of the solar radiation (*see* **5.2.6**);

$\rho_o(\lambda)$ = spectral external reflectance of the glazing; and

$\Delta\lambda$ = integration procedure are the same as in light transmittance (*see* **5.4.5.4**) except that the data points shall be chosen at the wavelengths given in Table 5.

In the case of multiple glazing, the spectral external reflectance ρ_o (λ) is calculated in accordance with **5.5.1**.

NOTE — The values in this table are calculated according to the trapezoidal rule.

5.2.8 *Solar Direct Absorptance*

The solar direct absorptance α_e shall be calculated from the following formula:

$$\tau_e + \rho_e + \alpha_e = 1$$

5.2.9 *Secondary Heat Transfer Factor Towards the Inside*

5.2.9.1 *Boundary conditions*

For the calculation of the secondary heat transfer factor towards the inside, q_i, the heat transfer coefficients of the glazing towards the outside, h_e, and towards the inside, h_i, are needed. These values mainly depend on the position of the glazing, wind velocity, inside and outside temperatures and, furthermore, on the temperature of the two external glazing surfaces.

As the purpose of this Section is to provide basic information on the performance of glazing, the following conventional conditions have been stated for simplicity:

a) Position of the glazing: vertical;

b) Outside surface: wind velocity approximately 4 m/s; corrected emissivity 0.837;

c) Inside surface: natural convection; emissivity optional; and

d) Air spaces are unventilated.

Under these conventional, average conditions, standard values for h_e and h_i are obtained:

$$h_e = 23 \text{ W/(m}^2\text{K)}$$

$$h_i = \left(3.6 + \frac{4.4\,\varepsilon_i}{0.837}\right) W/(m^2.K)$$

where

ε_i = corrected emissivity of the inside surface [for soda lime glass, $\varepsilon_i = 0.837$ and $h_i = 8$ W/(m^{2}K)].

If other boundary conditions are used to meet special requirements they shall be stated in the test report. Values for ε_i lower than 0.837 (due to surface coatings with higher reflectance in the far infrared) should only to be taken into account if condensation on the coated surface can be excluded.

5.2.9.2 *Single glazing*

The secondary heat transfer factor towards the inside, q_i, of single glazing shall be calculated using the following formula:

$$q_i = \alpha_e \frac{h_i}{h_e + h_i}$$

where

α_e = solar direct absorptance obtained from the in accordance with 5.2.5, and

h_e, h_i = heat transfer coefficients towards the outside and inside, respectively, in accordance with 5.2.9.1.

5.2.9.3 *Double glazing*

The secondary heat transfer factor towards the inside, q_i, of double glazing shall be calculated using the following formula:

$$q_i = \frac{\left(\frac{\alpha_{e1} + \alpha_{e2}}{h_e} + \frac{\alpha_{e2}}{\Lambda}\right)}{\left(\frac{1}{h_i} + \frac{1}{h_e} + \frac{1}{\Lambda}\right)}$$

where

α_{e1} = solar direct absorptance of the outer (first) pane within the double glazing;

α_{e2} = solar direct absorptance of the second pane within the double glazing;

Λ = thermal conductance between the outer surface and the innermost surface of the double glazing (*see* Fig. 8), in watts per square metre per Kelvin (W/m^2.K); and

h_e, h_i = heat transfer coefficients towards the outside and the inside, respectively in accordance with **5.2.9.1**.

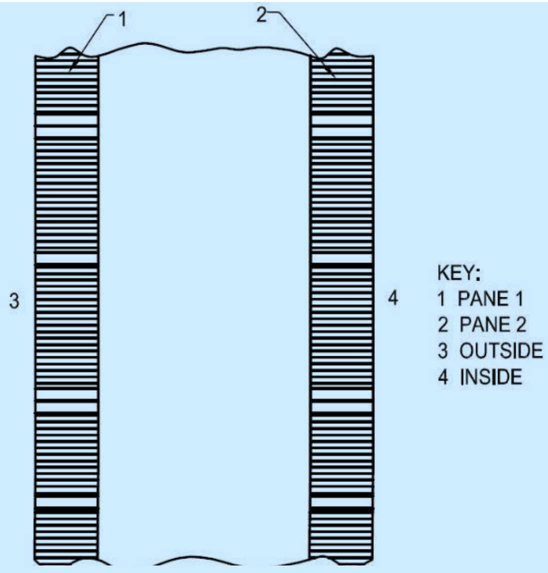

FIG. 8 ILLUSTRATION OF THE MEANING OF THERMAL CONDUCTANCE, Λ

Characteristics αe1 and αe2 are calculated as follows:

$$\alpha_{\mathrm{e1}} = \frac{\sum_{\lambda=300\ \mathrm{nm}}^{2\ 500\ \mathrm{nm}} \left\{ \alpha_1(\lambda) + \frac{\alpha_1'(\lambda)\tau_1(\lambda)\rho_2(\lambda)}{1-\rho_1'(\lambda)\,\rho_2(\lambda)} \right\} S_\lambda \Delta\lambda}{\sum_{\lambda=300\ \mathrm{nm}}^{2\ 500\ \mathrm{nm}} S_\lambda \Delta\lambda}$$

$$\alpha_{\mathrm{e2}} = \frac{\sum_{\lambda=300\ \mathrm{nm}}^{2\ 500\ \mathrm{nm}} \left\{ \frac{\alpha_2(\lambda)\tau_1(\lambda)}{1-\rho_1'(\lambda)\,\rho_2(\lambda)} \right\} S_\lambda \Delta\lambda}{\sum_{\lambda=300\ \mathrm{nm}}^{2\ 500\ \mathrm{nm}} S_\lambda \Delta\lambda}$$

where

$\tau_1(\lambda), \tau_2(\lambda), \rho_1(\lambda), \rho_1'(\lambda), \rho_2(\lambda)$ are as defined in light transmittance (*see* **5.4.5.4**)

$\alpha_1(\lambda)$ = spectral direct absorptance of the outer pane, measured in the direction of the incident radiation, given by the relationship:

$$\alpha_1(\lambda) = 1 - \tau_1(\lambda) - \rho_1(\lambda)$$

$\alpha_1'(\lambda)$ = spectral direct absorptance of the outer pane, measured in the opposite direction to the incident radiation, given by the relationship:

$$\alpha_1'(\lambda) = 1 - \tau_1(\lambda) - \rho'_1(\lambda)$$

$\alpha_2(\lambda)$ = spectral direct absorptance of the second pane, measured in the direction of the incident radiation, given by the relationship:

$$\alpha_2(\lambda) = 1 - \tau_2(\lambda) - \rho_2(\lambda)$$

$\Delta\lambda$ and the integration procedure are the same as in **5.4.5.4** except that the data points shall be chosen at the wavelengths given in Table 5.

The thermal conductance Λ shall be determined for a temperature difference of $\Delta T = 15$ °C across the sample and a mean temperature of the sample of 10 °C, or by measuring methods using the standard guarded hot plate method, or the standard heat flow metre method.

If another temperature difference ΔT across the sample and/or another mean temperature of the sample is used for the determination of the thermal conductance Λ to meet special requirements, this shall be stated in the test report.

5.2.9.4 *Multiple glazing with n > 2 components*

The secondary heat transfer factor towards the inside, q_i, of a multiple glazing with more than two components shall be calculated using the following formula:

$$q_i = \frac{\dfrac{\alpha_{e1} + \alpha_{e2} + \alpha_{e3} + \cdots + \alpha_{en}}{h_e} + \dfrac{\alpha_{e2} + \alpha_{e3} + \cdots + \alpha_{en}}{\Lambda_{12}} + \dfrac{\alpha_{e3} + \cdots + \alpha_{en}}{\Lambda_{23}} + \cdots + \dfrac{\alpha_{en}}{h_e}}{\dfrac{1}{h_i} + \dfrac{1}{h_e} + \dfrac{1}{\Lambda_{12}} + \dfrac{1}{\Lambda_{23}} + \cdots + \dfrac{1}{\Lambda_{(n-1)n}}}$$

where

α_{e1} = solar direct absorptance of the outer (first) pane within the *n*-fold glazing;

α_{e2} = solar direct absorptance of the second pane within the *n*-fold glazing;

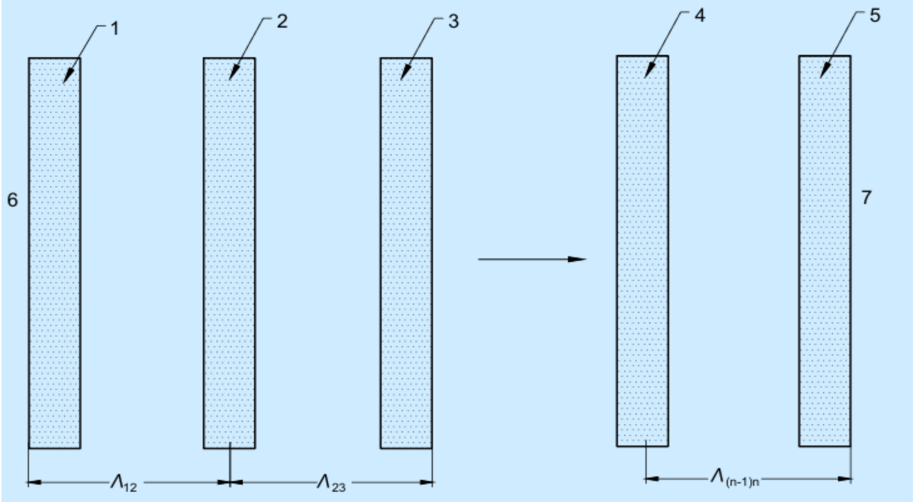
α_{en} = solar direct absorptance of the n^{th} (inner) pane of the *n*-fold glazing;

h_e, h_i = heat transfer coefficients towards the outside and towards the inside, respectively in accordance with **5.2.9.1**;

Λ_{12} = thermal conductance between the outer surface of the outer (first) pane and the centre of the second pane (*see* Fig. 9);

$\Lambda_{(n-1)n}$ = thermal conductance between the centre of the $(n-1)^{th}$ pane and the outer surface of the n^{th}(inner) pane (*see* Fig. 9); and

Λ_{23} = thermal conductance between the centre of the second pane and the centre of the third pane (*see* Fig. 9);



KEY:
1 PANE 1
2 PANE 2
3 PANE 3
4 PANE (n - 1)
5 PANE n
6 OUTSIDE
7 INSIDE

NOTE — For triple glazing, pane 3 corresponds to pane n.

FIG. 9 ILLUSTRATION OF THE MEANING OF THE THERMAL CONDUCTANCES Λ_{12}, Λ_{23}……..$\Lambda_{(n-1)\,n}$

The thermal conductances Λ_{12}, Λ_{23}........$\Lambda_{(n-1)n}$ shall be determined by iteration technique. The calculation of the direct solar absorptances α_{e1}, α_{e2},...α_{en} shall be performed using the methods given in 5.2.9.3.

As an example for the calculation of the direct solar absorptances the following procedure is given which consist of the following (n-1) steps for a glazing consisting of n components:

a) First step — calculate the spectral characteristics of a unit consisting of (n-1) components 2,3,.......n according to what has been prescribed in 5.4.5.4 and 6.1. Then combine this unit with the first (outer) pane as a double glazing;

b) Second step — calculate the spectral characteristics of a unit consisting of the (n-2) components 3,....,n and furthermore, those of a double glazing consisting of pane 1 and pane 2. These units are then combined as a double glazing. The sum $\alpha_{e1} + \alpha_{e2}$ is then obtained. This procedure is continued up to the last (n-1)th step; and

c) (n-1)th step — combine the (n-1) panes 1,2,... (n-1) and determine the spectral characteristics of this unit. This unit is then combined with the nth (inner) pane as a double glazing. From the second equation in 5.2.9.3, the sum α_{e1}, α_{e2} ...$\alpha_{e(n-1)}$ is obtained, that is with the known values α_{e1}, α_{e2},... $\alpha_{e(n-2)}$ from the previous steps $\alpha_{e(n-1)}$ is determined. α_{en} is obtained according to the expression of α_{e2} in 5.2.9.3.

In the case of triple glazing for the solar absorptances α_{e1}, α_{e2} and α_{e3} as a function of the spectral characteristics of the individual components of the unit, the following formulae are obtained:

$$\alpha_{e1} = \frac{\sum_{\lambda=300\text{ nm}}^{2\,500\text{ nm}} \left\{ \alpha_1(\lambda) + \frac{\tau_1(\lambda)\alpha'_1(\lambda)\rho_2(\lambda)\,[1-\rho'_2(\lambda)\,\rho_3(\lambda)] + \tau_1(\lambda)\tau_2^2(\lambda)\alpha'_1(\lambda)\,\rho_3(\lambda)}{[1-\rho'_1(\lambda)\,\rho_2(\lambda)].[1-\rho'_2(\lambda)\,\rho_3(\lambda)] - \tau_2^2(\lambda)\rho'_1(\lambda)\,\rho_3(\lambda)} \right\} S_\lambda \Delta\lambda}{\sum_{\lambda=300\text{ nm}}^{2\,500\text{ nm}} S_\lambda \Delta\lambda}$$

$$\alpha_{e2} = \frac{\sum_{\lambda=300\text{ nm}}^{2\,500\text{ nm}} \left\{ \frac{\tau_1(\lambda)\alpha_2(\lambda)\,[1-\rho'_2(\lambda)\,\rho_3(\lambda)] + \tau_1(\lambda)\tau_2(\lambda)\alpha'_2(\lambda)\,\rho_3(\lambda)}{[1-\rho'_1(\lambda)\,\rho_2(\lambda)].[1-\rho'_2(\lambda)\,\rho_3(\lambda)] - \tau_2^2(\lambda)\rho'_1(\lambda)\,\rho_3(\lambda)} \right\} S_\lambda \Delta\lambda}{\sum_{\lambda=300\text{ nm}}^{2\,500\text{ nm}} S_\lambda \Delta\lambda}$$

$$\alpha_{e3} = \frac{\sum_{\lambda=300\text{ nm}}^{2\,500\text{ nm}} \left\{ \frac{\tau_1(\lambda)\tau_2(\lambda)\alpha_3(\lambda)}{[1-\rho'_1(\lambda)\,\rho_2(\lambda)].[1-\rho'_2(\lambda)\,\rho_3(\lambda)] - \tau_2^2(\lambda)\rho'_1(\lambda)\,\rho_3(\lambda)} \right\} S_\lambda \Delta\lambda}{\sum_{\lambda=300\text{ nm}}^{2\,500\text{ nm}} S_\lambda \Delta\lambda}$$

where

$\tau_1(\lambda)$, $\tau_2(\lambda)$, $\tau_3(\lambda)$, $\rho_1(\lambda)$, $\rho'_1(\lambda)$, $\rho_2(\lambda)$, $\rho'_2(\lambda)$, $\rho_3(\lambda)$ are as defined in light transmittance;

$\alpha_1(\lambda)$, $\alpha'_1(\lambda)$ and $\alpha_2(\lambda)$ are as defined in 5.2.9.3 for double glazing;

$\alpha'_2(\lambda)$ = spectral direct absorptance of the second pane, measured in the opposite direction to the incident radiation, given by the relationship:

$$\alpha'_2(\lambda) = 1 - \tau_2(\lambda) - \rho'_2(\lambda)$$

$\alpha_3(\lambda)$ = spectral direct absorptance of the third pane, measured in the direction of the incident radiation, given by the relationship:

$$\alpha_3(\lambda) = 1 - \tau_3(\lambda) - \rho_3(\lambda)$$

$\Delta\lambda$ and the integration procedure are the same as in 5.4.5.4 except that the data points shall be chosen at the wavelengths given in Table 5.

For a glazing with more than three components, the formulae for the solar absorptances α_{e1}, α_{e2}, ..., α_{en} as a function of the individual components.

5.2.9.5 *Mean radiant temperature* (*MRT*)

Besides solar energy transmittance, heat gain and losses occur by radiation exchange between the glazing which influences thermal comfort of the occupants. Mean radiant temperature (MRT), which is defined as the uniform temperature of an imaginary enclosure in which radiant heat transfer from the human body is equal to the radiant heat transfer in the actual non-uniform enclosure, is used as a metric in thermal comfort assessment. MRT can be calculated by various methods, among which measuring with globe thermometer is the most common and is given by:

$$MRT = \sqrt[4]{{T_g}^4 + \frac{h_{cg}}{\varepsilon_g \sigma}(T_g - T_a)^4}$$

where

T_a = air temperature, in Kelvin;

T_g = black globe temperature, in Kelvin;

ε_g = emissivity of black globe;

σ = Stefane-Boltzmann constant; and

h_{cg} = convective heat transfer coefficient of the black globe.

5.2.10 *Thermal Transmittance due to Temperature Difference*

The other part to be looked at is the transfer of heat from outside to inside environment through the glass, due to the temperature difference. This is known as U-value, which is the rate of heat flow through one square metre of glazing when there is a temperature difference of 1 °C. The lower the U-value, the lesser is the heat transfer.

5.2.11 *Total Solar Energy Transmission*

The total solar energy transmitted into the room per unit area of glazing φ_{ei} is given by the relationship:

$$\varphi_{ei} = \varphi_e g$$

where

φ_e = incident solar radiation flux per unit area;

g = total solar energy transmittance of the glazing; and

The values of φ_e can be obtained from appropriate tables in meteorological literature.

NOTE — The SHGC/SF requirement for the glazing should be selected based on the prescriptive requirements are mentioned in Annex B.

5.2.11.1 *Additional heat transfer*

If the room temperature T_i differs from the outside temperature T_o, an additional heat transfer occurs in addition to φ_{ei}. This additional heat flow q_z can be calculated as follows:

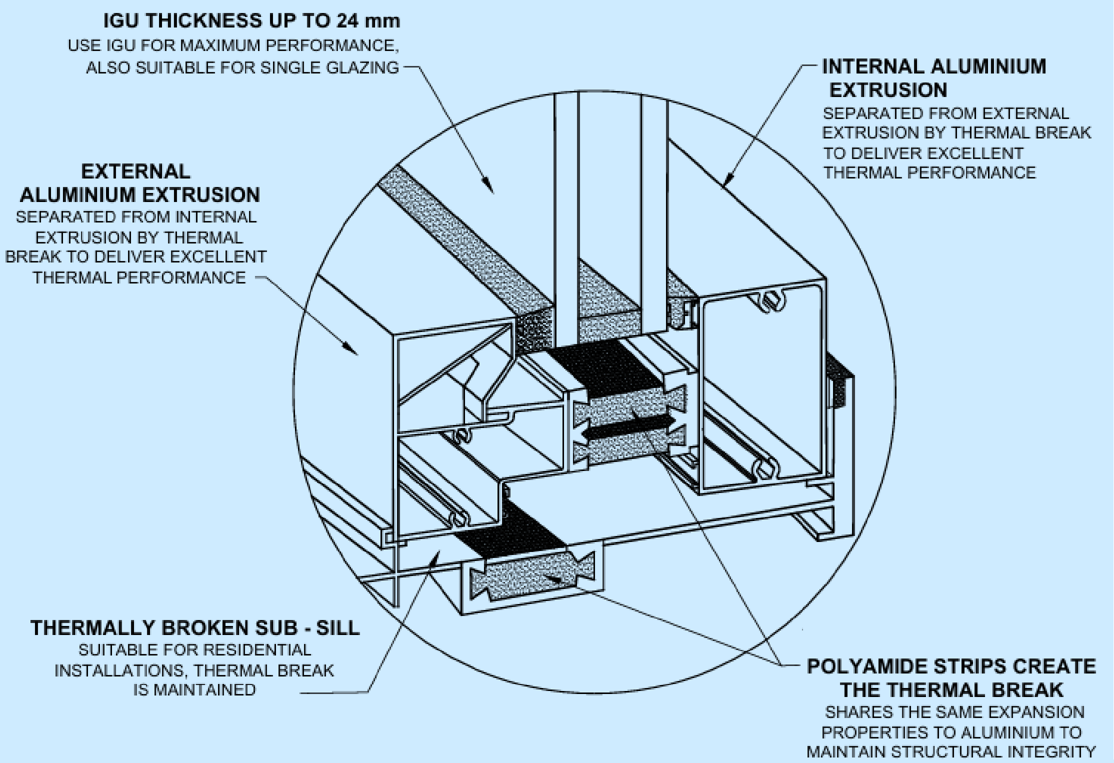
$$q_z = U\,(T_o - T_i)$$

where U is the U-value (thermal transmittance) of glazing.

5.2.12 *Frames*

These can contribute to a significant amount of energy gain and energy loss through the glazing system. For improved efficiency, some frames are designed with internal thermal breaks that reduce energy flow through the frame (*see* Fig. 10). The sealing between the openings and the window frames and between the opening sashes of windows and fixed portions are important areas to be addressed as major heat loss happens from this area due to poor design, selection and application of sealant material. Adequate provision shall also be made to ensure that the frames are not susceptible to water ingress in case of driving rain.

NOTE — As the evaluation of structural property differs from a monolithic profile, for evaluation of the structural property of thermally broken profile, the method described in Annex G of accepted standard [C-8(12)] shall be followed.



IGU THICKNESS UP TO 24 mm
USE IGU FOR MAXIMUM PERFORMANCE, ALSO SUITABLE FOR SINGLE GLAZING
INTERNAL ALUMINIUM EXTRUSION
SEPARATED FROM EXTERNAL EXTRUSION BY THERMAL BREAK TO DELIVER EXCELLENT THERMAL PERFORMANCE
EXTERNAL ALUMINIUM EXTRUSION
SEPARATED FROM INTERNAL EXTRUSION BY THERMAL BREAK TO DELIVER EXCELLENT THERMAL PERFORMANCE
THERMALLY BROKEN SUB - SILL
SUITABLE FOR RESIDENTIAL INSTALLATIONS, THERMAL BREAK IS MAINTAINED
POLYAMIDE STRIPS CREATE THE THERMAL BREAK
SHARES THE SAME EXPANSION PROPERTIES TO ALUMINIUM TO MAINTAIN STRUCTURAL INTEGRITY

FIG. 10 THERMALLY BROKEN ALUMINIUM FRAME ASSEMBLY FOR IMPROVED THERMAL PERFORMANCE IN GLAZING SYSTEMS

5.2.13 *Shading Systems*

These regulate the solar radiation incident on the glazing thereby reducing the effective solar heat gain coefficient of the glazing system. Besides reduction in direct solar gains inside the building, shading systems reduce the radiant heat gain from the glazing surface. Shading system design requires due consideration for the geographic location of the building, orientation of the facade, location of the system, and solar geometry. External shading systems are effective in solar control compared to internal shading systems (*see* Fig. 11). Shading systems may impact the daylight availability and the views available for occupants. Kinetic systems, either automated or manually operated, can be used to vary shading system positions dynamically based on solar position, daylight requirements and occupant preferences.

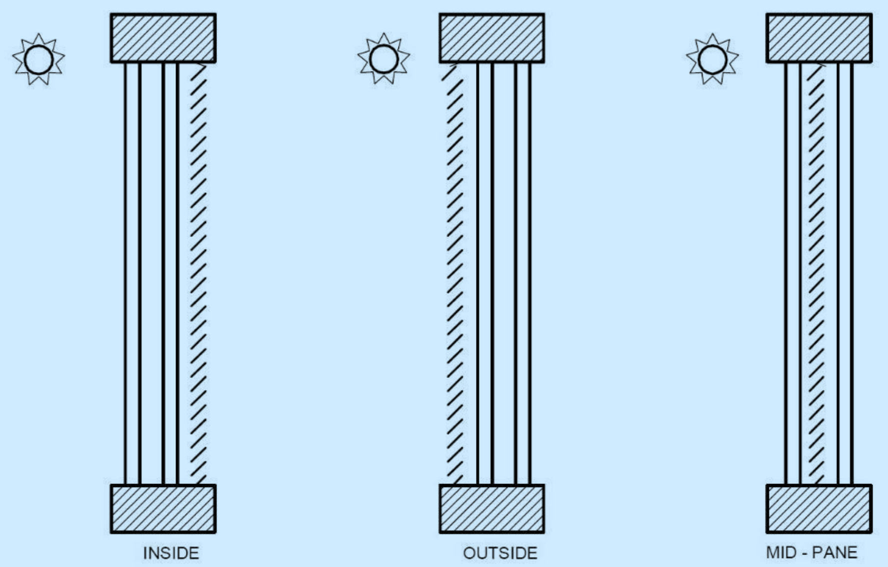


FIG. 11 PLACEMENT OF SHADING DEVICES FOR OPTIMAL SUN CONTROL IN GLAZING SYSTEMS

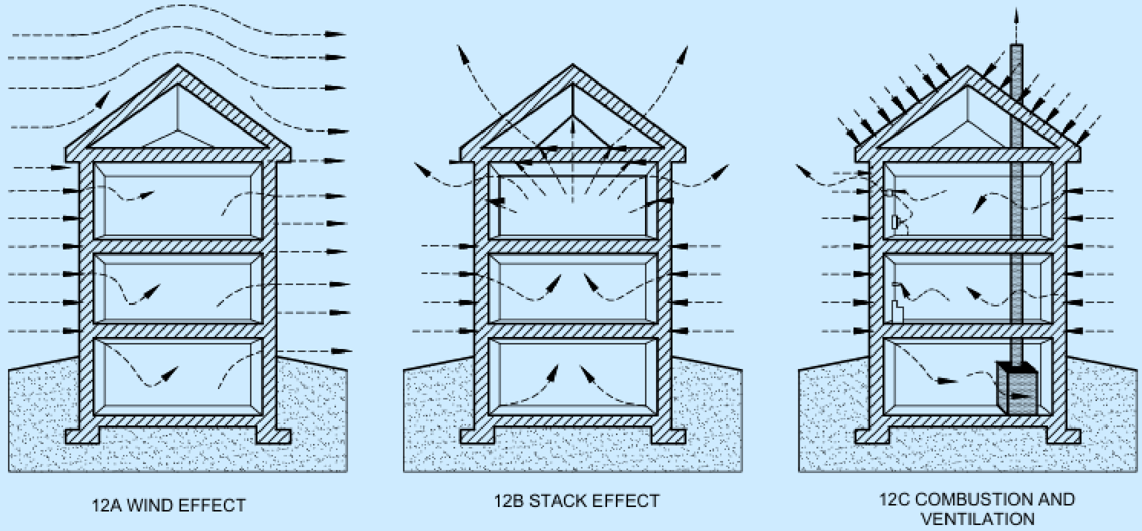
5.2.14 *Air Infiltration*

Inadequate control of airflow through the building envelope is often a primary factor contributing to premature building envelope failures. Air infiltration may be caused by wind pressure, stack pressure or fan pressure (*see* Fig. 12). Wind creates a positive pressure on the windward face and negative pressure on the leeward face, causing infiltration and exfiltration. Besides the positive or negative pressure created by the heating, ventilation and air conditioning system may lead to exfiltration or infiltration, respectively.

The stack effect is when warm air moves upward in a building because it is lighter than cold air and escapes out of the upper levels of the building, through penetrations and cracks in the building envelope or other openings. The rising warm air reduces the pressure in the base of the building, forcing cold air to infiltrate through open doors, windows, or other openings. The stack effect basically causes air infiltration on the lower portion of a building and exfiltration on the upper part. Mechanical equipment such as fans and blowers cause the movement of air within buildings and through enclosures, which can generate pressure differences. If more air is exhausted from a building than is supplied, a net negative pressure is generated, which can induce unwanted airflow through the building envelope.



12A WIND EFFECT

12B STACK EFFECT

12C COMBUSTION AND VENTILATION

FIG. 12 MECHANISMS OF AIR INFILTRATION: WIND EFFECT, STACK EFFECT, AND COMBUSTION AND VENTILATION IN BUILDING ENCLOSURES

5.2.14.1 *Considerations for controlling air infiltration*

a) Ensuring the continuity of each component serving its role in resisting infiltration, such as a window assembly or a curtain, and ensuring they are interconnected to prevent air leakage at the joints between materials, components, assemblies, and systems; and

b) Effective structural support shall be ensured so that all components can resist the positive or negative structural loads imposed on them by wind, stack effect, and HVAC fan pressures without rupture, displacement or undue deflection, thereby resisting air infiltration through them. Design considerations shall ensure that these loads are safely transferred to the structure and provision of adequate resistance to these pressures by use of fasteners, tapes, adhesives, etc.

Inadequate sealing of the glazing system may lead to energy gains and losses, thereby affecting thermal comfort and increasing the cooling and heating energy demand. If moisture-laden air infiltrates through the glazing system, the moisture may, under certain environmental conditions condense, especially in cold climates.

5.3 Methods for Improving Thermal Insulation

Glass readily conducts energy and so is a poor insulator. To improve resistance to energy transfer, insulating glass units, coupled glazing or high performance coatings can be used. Increasing the thickness of the glass makes little difference to the U-value of the glazing.

5.3.1 *Use of Low Emissivity Coatings*

Low emissivity (low-E) coatings have surface emissivity of less than 0.2. The use of such a solar control low-E coating on glass improves the thermal insulation. They are most efficient when used on the cavity surfaces of insulating glass units.

5.3.2 *Solar Control Glass*

Solar control glass can be manufactured in several forms. The function of solar control glass is to reduce the total solar energy transmittance, which usually leads to a decrease in the transmission of the visible part of the solar spectrum. However, some tints and coatings are able to attenuate preferentially non-visible solar radiation, leaving the transmission of the greater proportion of the visible radiation largely unchanged.

The application of ceramic frit-fired into the surface of the glass can also be used to modify the energy and light transmission of the glass. The effect can be varied across a pane depending on the screen print pattern. Manufacturers should be consulted for specific details.

Solar control glass can be used in single glazed or double glazed unit depending upon the site requirements. The relationship between light transmission and total solar energy transmission is expressed as the light/energy ratio.

There is no optimum light/energy ratio. The selection of an appropriate product depends on the requirements of the building. Solar gain may be relatively high for making use of passive solar gains, or low to reduce air conditioning loads. Light transmission will depend on the extent to which daylight is used to obviate artificial lighting.

Some solar control glasses can be toughened or heat strengthened and gives a means of raising the design stress and enhances safety of thermal fracture. The following are the common varieties.

NOTE — Some manufacturers use this as a descriptive code, quoting a light transmission figure followed by a total solar energy transmission figure.

a) *Body tinted glass* (*for increased absorption*) — Solar control properties and colour vary with the thickness of the glass. When used in insulating glass units, body tinted glass should be positioned as the outer pane because the energy due to the absorbed radiation is more easily dissipated to the outside.

b) *Reflective coated glass* — It uses the principle of increasing the direct reflection to maximize solar energy attenuation. In comparison with clear glass, its absorption of solar energy is also increased. An informative annex on test requirements is given at Annex C.

The advantages of such glass types are:

1) Greater performance range than body tinted glass;
2) Higher performances (greater solar energy attenuation);
3) Light/energy ratios nearer to the theoretical limit; and
4) A range of colour appearances in transmission and reflection.

The coatings may be placed on to body-tinted glass to extend the range of performances.

NOTES

1 Compared with a float glass surface, these reflective coatings (owing to their composition) exhibit lower levels of emissivity which improves their *U*-value.
2 Performance data in comparison to clear glass can be had from manufacturers.

c) *Laminated glass* — It is commonly manufactured with clear glass and clear interlayers, but solar control properties can be incorporated into laminated glass by including either solar control glass or tinted interlayers or both.

Laminated glass with clear interlayers and solar control glass exhibit similar properties to the solar control glass from which it is made.
Laminated glass with a tinted interlayer acts in a similar manner to body tinted glass, by absorbing the solar radiation, but with a different range of colours and performances.

NOTE — Performance data in comparison to clear glass can be had from manufacturers. Performances of a typical range of laminated glass products with clear glass and tinted interlayers can be had from manufacturers.

d) *Insulating glass units* — These are used primarily for improved thermal transmittance (*U*-value) (*see* **5.2.10**), but can also improve the total solar energy transmittance. This improvement is a result of the incorporation of a second pane of glass together with the hermetically sealed air space. The second glass pane can be of any glass type. Outer pane can be solar control low emissivity glass (surface 2) and inner pane can be clear glass (*see* Fig. 13A). The other option is outer pane can be solar control glass (surface 2) and inner pane with low emissivity coating glass (surface 3) (*see* Fig. 13B).

NOTES

1 Soft coat low emissivity glass can be used as the hermetically sealed airspace protects the coating.
2 Performances of a typical range of insulating glass units with clear float inner pane or with hard/soft coat low emissivity glass inner pane can be had from manufacturers.

FIG. 13 CONFIGURATIONS OF INSULATING GLASS UNITS

5.3.3 *Reducing Thermal Transmittance of Glazing System*

5.3.3.1 *Increasing the width of the air space*

Enhanced thermal insulation can be achieved by increasing the width of the airspace. However, there is a convection of the gas in the cavity.

5.3.3.2 *Using gases of lower thermal conductivity*

Replacing the air in the cavity with, for example, argon/krypton, can improve the thermal insulation.

5.3.3.3 *Inhibiting convection within the air space*

Filling the cavity with cellulose material reduces convection and makes the cavity a more efficient insulator. However, this usually results in loss of vision, since the materials are, at best, translucent.

5.3.3.4 *Evacuation of the air space*

In theory, a vacuum shall eliminate energy transfer by conduction and convection. However, a vacuum puts high demands on the glass from the external air pressure.

NOTE — Evacuation of the air space is currently considered to be technically impractical.

5.3.3.5 *Evaluation of type of spacer used in double glazed unit*

Thermal performance of the glazing system for conduction can be improved by changing the material of the spacer.

5.3.3.6 *Typical U-values of glass products*

Table 6, Table 7 and Table 8 give typical *U*-values.

	c) 60 percent shaded		0.56

NOTE — Indicative values, actual value of the system to be measured using either approved simulation software or testing at laboratory.

5.3.4 *Thermal Safety of Glass*

Thermal safety of glass should be assessed considering the amount of radiation incident on the surface and the thermal capabilities of the glass. For example, the solar radiation intensity on the glass surface should be determined along with the air temperature range applicable to the location of the building. These measurements, together with the energy transfer coefficients and the glass absorption allow determination of the appropriate basic temperature difference between the central area of the glass and its edge. The difference is related to the thermal stress and then modified for the type of glazing system, taking account of extraneous effects resulting from curtains, blinds, back-up walls, proximity to heaters, etc to derive a stress in actual service conditions.

NOTES

1 High air temperatures, low rates of air movement, and the insulation provided by curtains, blinds, back-up walls and multiple glazing tend to reduce the loss of energy and uphold the centre temperature. Low temperatures at the edges are maintained by conduction from the glass through the frame to a cold building structure with a large thermal capacity.

2 Advice may be sought from the manufacturer of glass as to the methods for assessing the thermal safety of the glass.

The resultant service stress should then be compared with the design stress for the glass. If on comparison, the service stress is less than or equal to the design stress, the glass and glazing system may be accepted as thermally safe provided, that the edges of the glass are of adequate quality.

NOTE — Where the application of a solar control film is being considered to existing glazing, advice should be sought from the manufacturer on the effect of any additional thermal stress likely to be induced in the glass.

The normal mode of thermal breakage of glass is by the action of tensile stress located in and parallel to an edge, and so the breaking stress of the glass is mainly dependent on the extent and position of flaws in the edges. The condition of the glass edge is therefore extremely important.

Solar control glasses should not be nipped to size and any panes with shelled or vented edges should not be accepted for glazing in orientations subject to direct sunlight. Although a wheel-cut edge is the most satisfactory, laminated glasses with worked edges may be used.

Where clean-cut edges are not permitted, arises should be created by a wet process, working parallel to the edge and not across the thickness, and the design implications of such an action should be examined.

Where solar control glasses are to be used in sliding doors and windows there is always the possibility that, when opened during sunny periods, the overlapping will function as double glazing with little ventilation in the air space, and it is this condition that should be assumed in assessing the thermal safety of glass.

Thermal safety assessment is based on the behaviour of glass in good condition and properly glazed. Even if the glass is shown to be thermally safe, this depends on close adherence to the recommend glazing procedures. All necessary precautions should be taken to see that only glass with edges of an acceptable condition is used. The glass should be stored and handled so that no contact with hard bodies can damage the edges and each pane or insulating glass unit should be carefully examined immediately before glazing.

5.3.5 *UV-Transmittance*

The UV-transmittance of glazing is the fraction of the incident solar radiation transmitted by the glazing in the 300 nm to 380 nm range (UV-B range from 300 nm to 315 nm and UV-A range from 315 nm to 380 nm). The UV-transmittance τ_{UV} is calculated as follows:

$$\tau_{\mathrm{UV}} = \frac{\sum_{\lambda=300\ \mathrm{nm}}^{380\ \mathrm{nm}} \tau(\lambda) S_\lambda\, \Delta\lambda}{\sum_{\lambda=300\ \mathrm{nm}}^{380\ \mathrm{nm}} S_\lambda\, \Delta\lambda}$$

where

S_λ = relative spectral distribution of UV radiation;

$\tau(\lambda)$ = spectral transmittance of the glazing; and

$\Delta\lambda$ and the integration procedure are the same as **5.4.5.4** except that the data points shall be chosen at the wavelength given in Table 10.

This average extends over the defined UV-portion of the solar spectrum. It may not be correlated with solar radiation damage of materials and skin.

xx)	370	0.108 987
xxi)	375	0.113 837
xxii)	380	0.058 351

NOTE — The values in this table are calculated according to the trapezoidal rule.

5.4 Daylight Transmission

Good glazing system design can, by reducing reliance on artificial lighting, can be one of the largest single means of saving energy and should be carefully considered.

Account should be taken of shape of the room, window orientation, occupancy patterns and task, together with the relationship of windows to surrounding buildings and other obstruction. As with task lighting, possible solar overheating might result and similar precautions should be taken.

5.4.1 *Light Transmission Properties of Window*

Light transmission is defined as the fraction of visible light at normal incidence transmitted through the glazing. For properties of plastic glazing sheet materials, manufacturers may be consulted.

Dirt on glazing reduces the light transmission, often by an appreciable extent before becoming noticeable. To ensure day lighting levels are adequate, an allowance for the reduced light transmission should be made in day lighting calculation by introducing a ‘dirt factor’ between 0.7 and 1.0. Regular cleaning of glass and plastic glazing sheet materials is therefore important.

5.4.2 *Glare*

5.4.2.1 *General*

Glare results from excessive contrast of illumination, or from an excess of illumination in the field of view. Reaction to it is subjective. When correctly designed, natural lighting should not result in glare problem.

NOTE — Contrasts in excess of 10 : 1 in illumination in different parts of the field of view might give rise to glare in some form.

5.4.2.2 *Disability glare*

Disability glare is glare which impairs the visibility of objects without necessarily causing discomfort.

During a sunny day, even a light transmission of the glazing resulting in 10 000 lux or lower, is likely to cause disability glare.

Glare can be reduced by some form of mechanical shading, for example a canopy, an overhanging floor, a balcony or a louvre system. Alternatively, internal screening can be provided by louvres or blinds.

NOTE — Any fixed shading system reduces the amount of natural light entering the building throughout the year, irrespective of whether there is a glare problem at any particular time.

It may also be possible to re-orientate the glazing to avoid entry of direct solar radiation. Alternatively, the interior layout can be suitably designed to eliminate glare.

5.4.2.3 *Discomfort glare*

Glazing products with light transmission lower than 50 percent can ameliorate discomfort glare. These products decrease the sky luminance components but permanently reduce the admission of daylight. Alternatively, shading devices, internal or external, movable or fixed, may be used.

Other methods of reducing the problems of glare should be considered, including,

a) installation of windows in more than one wall to raise the general background illumination and, in so doing, to reduce the contrast between a window and its surrounding surfaces;

b) use of light coloured matt finishes for the window frames and the surrounding surfaces;

c) splayed reveals, to assist in reducing the contrast between the window and its surroundings;

d) use of slender glazing bars and transoms of high reflectance; and

e) lowering window sills to allow increased illumination to enter, which increases the adaptation level and reduces the likelihood of discomfort glare.

5.4.3 *Diffusion and Obscuration*

The nature of some glazing products (for example, patterned or acid etched glass) can cause the direct incident solar beam to be scattered diffusely. Hence the window might assume an uncomfortable high brightness and become a discomfort glare source in its own right. Diffusing glazing used within the normal field of view should be used with caution.

5.4.4 *Fading*

Most materials can fade when subjected to either daylight (particularly direct sunlight) or artificial light. Fading is a complex phenomenon involving many chemical reactions, initiated or accelerated by light of different wavelengths. Generally, the better quality dyes and pigments fade relatively slowly and react only to the shorter wavelengths (ultraviolet and the blue end of the visible spectrum). Other materials can fade quickly and might do so under light of much longer wavelengths. It is the combination of wavelength, available light and transmission which determines glass selection to minimise fading, not simply the UV transmission.

5.4.5 *Determination of Characteristic Parameters*

5.4.5.1 *General*

The characteristic parameters are determined for quasi-parallel, almost normal radiation incidence.

5.4.5.2 *Test setup*

The samples shall be irradiated by a beam whose axis is at an angle not exceeding 10° from the normal to the surface. The angle between the axis and any ray of the illuminating beam shall not exceed 5°.

The characteristic parameters are as follows:

a) spectral transmittance $\tau(\lambda)$, the spectral external reflectance $\rho_o(\lambda)$ and the spectral internal reflectance $\rho_i(\lambda)$ in the wavelength range of 300 nm to 2 500 nm;

b) light transmittance τ_V, the external light reflectance $\rho_{v,0}$ and the internal light reflectance $\rho_{v,i}$ for illuminant D65;

c) solar direct transmittance τ_e and the solar direct reflectance ρ_e;

d) total solar energy transmittance (solar heat gain co efficient SHGC) g; and

e) UV-transmittance τ_{UV};

When calculating the characteristic parameters of multiple glazing, the spectral data of each glass component is to be used instead of integrating data of the complete unit.

5.4.5.3 *Performance requirements of optical measurements*

Optical measurements in transmission and reflection require special care to achieve accuracy in transmittance and reflectance of about ± 0.01.

The wavelength calibration and the photometric linearity of commercial spectrophotometers shall be checked periodically using reference materials obtained from metrological laboratories.

The wavelength calibration shall be performed by measuring glass plates which feature relatively sharp absorption bands at specified wavelengths; the photometric linearity shall be checked using grey filters with a certified transmittance.

For reflectance measurements, reference materials having reflection behaviour (that is, reflectance level and ratio of diffuse and direct reflectance).

Thick samples (that is laminated glass or insulating units) can modify the optical path of the instrument's beam as compared to the path in air and therefore the sample beam hits an area of the detector having a different responsivity.

A similar source of inaccuracy occurs in case of samples with significant wedge angles which deflect the transmitted (and reflected) beams. It is recommended to check the reproducibility by repeating the measurement after rotating the sample.

Additionally, in the case of reflectance measurements, glass sheets cause a lateral shear of the beam reflected by the second surface, causing reflectance losses (whose extent is particularly evident in the case of thick and/or wedged samples). This source of inaccuracy shall be taken into account particularly in the case of reflectance measurements through the uncoated side. In order to quantify and correct systematic errors, it is recommended to use calibrated reflectance standards with a thickness similar to the unknown sample.

In the case of diffusing samples (or samples with a non-negligible diffusing component or wedged samples), transmittance and reflectance measurements shall be performed using integrating spheres whose openings are sufficiently large to collect the entire diffusely transmitted or reflected beam. The sphere diameter shall be adequate and the internal surface adequately coated with a highly diffusing reflectance material, so that the internal area can provide the necessary multiple reflections. Reference materials with characteristics similar to the unknown sample as specified above shall be used. If the transmittance or reflectance curve recorded by the spectrometer exhibits a high level of noise for some wavelengths, the values to be considered for those wavelengths should be obtained after a smoothing of the noise.

5.4.5.4 *Light transmittance*

Light transmittance is the measure of the amount of light passing through the glazing. The visible light lies between the wavelength 380 nm and 780 nm. The light transmission of the glazing depends on the substrate type and coating layer done on the base glass.

The light transmittance, τ_v of glazing shall be calculated using the following formula:

$$\tau_{\mathrm{v}} = \frac{\sum_{\lambda=380\ \mathrm{nm}}^{780\ \mathrm{nm}} \tau(\lambda) D_\lambda\, V(\lambda)\, \Delta\lambda}{\sum_{\lambda=380\ \mathrm{nm}}^{780\ \mathrm{nm}} D_\lambda\, V(\lambda) \Delta\lambda}$$

where

D_λ = relative spectral distribution of illuminant D65;

$\tau(\lambda)$ = the spectral transmittance of glazing;

$V(\lambda)$ = spectral luminous efficiency for photopic vision defining the standard observer for photometry; and

$\Delta\lambda$ = wavelength interval.

Table 11 indicates the values for $D_\lambda V(\lambda)\Delta\lambda$ for wavelength intervals of 10 nm. The table has been drawn up in such a way that $\Sigma D_\lambda V(\lambda)\Delta\lambda = 1$.

In the case of multiple glazing, the spectral transmittance $\tau(\lambda)$ shall be obtained by calculation from the spectral characteristics of the individual components. Alternatively, measurements on non-diffusing multiple units may be performed using an integrating sphere. This may be achieved after reducing the interspaces under conditions that allow the collection of the whole transmitted beam.

The calculation of the spectral transmittance $\tau(\lambda)$ shall be performed using methods such as algebraic manipulation. Any algorithm that can be shown to yield consistently the correct solution is acceptable.

For the calculation of $\tau(\lambda)$ as well as for the calculation of spectral reflectance the following symbols for the spectral transmittance and spectral reflectance of the individual components are used:

$\tau_1(\lambda)$ = spectral transmittance of the outer (first) pane;

$\tau_2(\lambda)$ = spectral transmittance of the second pane;

$\tau_n(\lambda)$ = the spectral transmittance of the n^{th} (inner) pane (for example, for triple glazing $n= 3$);

$\rho_1(\lambda)$ = spectral reflectance of the outer (first) pane measured in the direction of incident radiation;

$\rho'_1(\lambda)$ = spectral reflectance of the outer (first) pane measured in the opposite direction of incident radiation;

$\rho_2(\lambda)$ = spectral reflectance of the second pane measured in the direction of incident radiation;

$\rho'_2(\lambda)$ = spectral reflectance of the second pane measured in the opposite direction of incident radiation;

$\rho_n(\lambda)$ = spectral reflectance of the n^{th} (inner) pane measured in the direction of incident radiation;

$\rho'_n(\lambda)$ = spectral reflectance of the n^{th} (inner) pane measured in the opposite direction of incident radiation.

For the spectral transmittance $\tau(\lambda)$ as a function of the spectral characteristics of the individual components of the unit, the following formulae are obtained:

a) For double glazing; and

b) For triple glazing.

For multiple glazing with more than three components, relationships similar to above expressions are found to calculate $\tau(\lambda)$ of such glazing from the spectral characteristics of the individual components.

As an example for calculating $\tau(\lambda)$ according to the procedures of this Section, a glazing composed of five components may be treated as follows:

1) First consider the first three components as triple glazing and calculate the spectral characteristics of this combination;

2) Next, run the same procedure for the next two components as double glazing; and

3) Then calculate $\tau(\lambda)$ for the five component glazing, considering it as double glazing consisting of the preceding triple and double glazing.

The light transmission requirement for the glazing should be selected in accordance with relevant Indian Standards.

5.5 Light Reflectance

5.5.1 *External Light Reflectance of Glazing*

External light reflectance corresponds to the amount of sunlight reflected by the external glass surface. The amount of light reflection depends on the type of base glass (substrate tint) and the position of coating on the glass surface.

The external light reflectance of glazing $\rho_{v,o}$ shall be calculated using the following formula:

$$\rho_{v,o} = \frac{\sum_{\lambda=380\text{ nm}}^{780\text{ nm}} \rho_o(\lambda) D_\lambda V(\lambda)\,\Delta\lambda}{\sum_{\lambda=380\text{ nm}}^{780\text{ nm}} D_\lambda V(\lambda)\Delta\lambda}$$

where

$\rho_o(\lambda)$ = spectral external reflectance of glazing, and D_λ, $V(\lambda)$, $\Delta\lambda$ and the integration procedure are defined in 5.4.5.4.

For multiple glazing, the calculation of the spectral external reflectance $\rho_o(\lambda)$ shall be performed using the same methods as given in 5.4.5.4 for the calculation of the spectral transmittance $\tau(\lambda)$.

For the spectral external reflectance $\rho_o(\lambda)$ as a function of the spectral characteristics of the individual components of the unit, the following formulae are applied:

a) For double glazing:

$$\rho_o(\lambda) = \rho_1(\lambda) + \frac{\tau_1^2(\lambda)\,\rho_2(\lambda)}{1 - \rho_1'(\lambda)\,\rho_2(\lambda)}$$

b) For triple glazing:

$$\rho_o(\lambda) = \rho_1(\lambda) + \frac{\tau_1^2(\lambda)\,\rho_2(\lambda)[1 - \rho_2'(\lambda)\,\rho_3(\lambda)] + \tau_1^2(\lambda)\,\tau_2^2(\lambda)\,\rho_3(\lambda)}{[1 - \rho_1'(\lambda)\,\rho_2(\lambda)].[1 - \rho_2'(\lambda)\,\rho_3(\lambda)] - \tau_2^2(\lambda)\rho_1'(\lambda)\,\rho_3(\lambda)}$$

For multiple glazing with more than three components, relationships similar to above equations are found to calculate $\rho_o(\lambda)$ of such glazing from the spectral characteristics of the individual components.

As an example for calculating $\rho_o(\lambda)$, a glazing composed of five components may be treated in the same way as described in 5.4.5.4.

5.5.2 *Internal Light Reflectance of Glazing*

Internal light reflectance corresponds to the amount of light reflected by the inner glass surface. The amount of light reflection depends on the type of base glass (substrate tint) and the position of coating on the glass surface.

The internal light reflectance of glazing $\rho_{\text{v,i}}$ shall be calculated using the following formula:

$$\rho_{\text{v,i}} = \frac{\sum_{\lambda=380\text{ nm}}^{780\text{ nm}} \rho_{\text{i}}(\lambda) D_\lambda\, V(\lambda)\, \Delta\lambda}{\sum_{\lambda=380\text{ nm}}^{780\text{ nm}} D_\lambda\, V(\lambda) \Delta\lambda}$$

where

$\rho_{\text{i}}(\lambda)$ = spectral internal reflectance of glazing; and

$D\lambda$, $V(\lambda)$, $\Delta\lambda$ and the integration procedure are as defined in light transmittance in 5.4.5.4.

For multiple glazing, the calculation of the spectral internal reflectance $\rho_{\text{i}}(\lambda)$ shall be performed using the same methods as given in **5.4.5.4** for the calculation of the spectral transmittance $\tau(\lambda)$.

For the spectral internal reflectance $\rho_{\text{i}}(\lambda)$ as a function of the spectral characteristics of the individual components of the unit, the following formulae are applied.

b) *For double glazing:*

$$\rho_i(\lambda) = \rho_2'(\lambda) + \frac{\tau_2^2(\lambda)\, \rho_1'(\lambda)}{1 - \rho_1'(\lambda)\, \rho_2(\lambda)}$$

c) *For triple glazing:*

$$\rho_i(\lambda) = \rho_3'(\lambda) + \frac{\tau_3^2(\lambda)\, \rho_2'(\lambda)[1 - \rho_2(\lambda)\rho_1'(\lambda)] + \tau_3^2(\lambda)\, \tau_2^2(\lambda)\rho_1'(\lambda)}{[1 - \rho_3(\lambda)\, \rho_2'(\lambda)].[1 - \rho_2(\lambda)\rho_1'(\lambda)] - \tau_2^2(\lambda)\, \rho_3(\lambda)\rho_1'(\lambda)}$$

For multiple glazing with more than three components, relationships similar to above expressions are found to calculate $\rho_{\text{i}}(\lambda)$ of such glazing from the spectral characteristics of the individual components.

5.6 Energy Design Considerations

5.6.1 *General*

Glass and glazing system design shall enhance daylighting into the building, improve the views to outdoor environments for the occupants, minimize the energy gains in hot climates, energy losses in cold climates and facilitate air movement in naturally ventilated spaces.

Fenestration, glazing and shading systems shall be designed by considering the climate characteristics, solar geometry, design sky conditions, orientation of the facade and building use. Effective design of the glazing system can minimize energy gains during summer and energy losses during winter. Height of the vision panel and the lintel height can be effectively adjusted to optimize the daylight penetration into the building.

5.6.2 *Design factors*

The following factors/components of a glazing system shall be considered during design for achieving energy efficiency:

a) Light transmittance and glare,

b) Thermal transmittance (solar heat gain co-efficient and U-value),

c) Fenestration size and placement,

d) Thermal properties of the frames,

e) Shading devices, and

f) Air infiltration.

5.6.3 *Analysis for Glazing System Selection*

5.6.3.1 *Building orientation and solar geometry analysis*

Optimal building orientation is a critical aspect for climate responsive design. Knowledge of the solar geometry at a site is essential for designing building facades to regulate energy and daylight transmission as well as reduce glare and overheating inside the building. Choice of glass and the shading system can considerably vary based on orientation of the facade and the solar geometry. A well oriented building maximises daylighting through its facades, thereby reducing the need for artificial lighting. Such building regulates the energy gains and losses through the facade, thereby minimizing thermal discomfort and cooling and heating energy demand.

5.6.3.2 *Solar insolation and shading analysis*

Design of glazing system is driven by the insolation levels on the facade, the desirable energy gains/losses and daylight requirements for a given building. Solar insolation varies with geographic location, orientation of the facade, time of the day and season. Direct solar incident radiation is the energy transmitted from the sun, which lies between the wavelength range of 250 nm and 2 500 nm. Solar radiation typically consists of 3 percent ultraviolet light, 42 percent visible light, and 55 percent infrared light. Infrared radiation is the major heat carrying radiation, followed by visible light. Analysing solar radiation helps to assess its impact on the building's elevations, allowing for a better understanding of how this influences the building's performance. Solar insolation and shading analysis are employed for determining optimum SHGC and U-value of glass, U-value of the frame and the design of shading system necessary for minimizing the energy gains and losses through the facade.

5.6.3.3 *Daylight analysis*

Daylight analysis is used to assess the penetration of natural light on the building floor plan or at the working plane level. A good lighting strategy involves optimizing the glazed area, increasing the daylight autonomy and thereby reducing the dependency on artificial lighting. Using a glass with optimal light transmission can go a long way in curtailing the dependence on artificial lighting. Additionally, the presence of natural light alleviates the claustrophobic feeling often associated with buildings that have limited glazing and outdoor views. Daylight calculations are conducted for overcast conditions to represent the worst-case scenario for outdoor lighting levels. Detailed methods for daylight analysis are provided in good practice [C-8(13)].

Any glass with enhanced energy performance will inevitably reduce the amount of daylight transmitted, even though it remains transparent for outward vision. The higher the demand for energy performance, the greater the compromise on daylight. Therefore, the selection of glass should begin by assessing the daylight requirements and deciding the optimum visible light transmittance (VLT). This approach helps narrow down the options, allowing for the selection of glass that provides the best performance for the specified VLT while also considering cost and aesthetics.

Floor plate geometry plays an important role as the daylight distribution will depend on the depth of the plate from the glazed area. Planforms incorporating courtyard and atrium have a great advantage of harnessing maximum daylight.

5.6.4 *Integrated Design Approach*

Glass and glazing system design shall duly consider the trade-offs in enhancing daylight availability, maximizing or minimizing the heat gains/losses, reduction in glare and improving views for the occupants. Table 12 provides the relation between glazing system parameters and different performance attributes.

Table 12 Relation Between Glazing System Parameters and Different Performance Attributes

(*Clause* 5.6.4)

Sl No.	Performance Attributes	Glazing System Parameters				
		VLT	U-Value	SHGC	Shading system	Fenestration size
(1)	(2)	(3)	(4)	(5)	(6)	(7)
i)	Daylight	∝	–	ID	$\frac{1}{\propto}$	∝
ii)	View	∝	–	ID	$\frac{1}{\propto}$	∝
iii)	Heat transfer	–	∝	∝	$\frac{1}{\propto}$	∝
iv)	Ventilation	–	–	–	$\frac{1}{\propto}$	∝

∝: directly proportional; $\frac{1}{\propto}$: Inversely proportional; ID: Indirect relationship

NOTE — The effects may vary depending on the geographic location, orientation of the facade and on-site and off-site features. The factors also have inter-dependencies.

5.7 Window Design Guideline for Non-Conditioned/Mixed Mode Buildings

In non-conditioned spaces, windows typically use single-glazed units, as they are often opened to allow ventilation. In such buildings, shading devices play a critical role in the thermal performance of windows. Considerations for selecting type of window and the necessary design considerations for energy efficiency and natural ventilation may be made in accordance with the relevant guidelines/best practices (Handbook on 'Sustainability in Buildings').

NOTE — Air infiltration Class B in accordance with accepted standard [C-8(14)] is adequate for non-conditioned buildings.

6 STRUCTURAL PARAMETERS AND FIRE SAFETY

6.1 Determination of Appropriate Glass Thickness

6.1.1 *General*

This Section gives provisions to determine the minimum glass thickness to be used to resist the ultimate limit state design wind pressures. However, the location of the glass within the building require additional considerations, such as safety with respect to human which may impose either a minimum glass thickness above the basic calculation of this part or a provision for a specific glass type or both.

In addition to the provisions herein, the design requirements such as wind loads determined in accordance with good practice [C-8(15)] and the serviceability deflection requirement limit given in this Section shall have to be complied.

The provisions under **6** are applicable provided the following parameters are satisfied:

a) Ultimate limit state wind pressure shall not be greater than 10 kPa;

b) For laminated glass, the two sheets may be of equal or unequal thickness and the interlayer material is either polyvinyl butyral or an equivalent type of interlayer with a modulus of elasticity of about 24 MPa and a Poisson's ratio of 0.50 at 20 °C;

c) Design flexural tensile strength of glass depends upon the design strength obtained after applying a factor of safety of 2.5. The minimum design strength of normal glass for thickness up to 6 mm is 16.7 N/mm^2 and for thickness above 6 mm is 15.2 N/mm^2.

6.1.2 *Design Considerations*

The following design considerations shall be taken into account in determination of appropriate thickness of glass:

a) Maximum area of glass panel is restricted to 15 m^2;

b) Maximum span of glass panel is restricted to 4 m;

c) Aspect ratio of the glass panel should be greater than 1.5. If it is less than 1.5, next higher available thickness should be selected in order to reduce the stress level;

d) Factor of safety applied is 2.5 considering the variability in strength of glass;

e) Applicable to normal, reflective, laminated, tempered and insulating glass;

f) Applicable to rectangular panels properly secured;

g) Design minimum thickness of laminated glass will be the maximum value of thickness in accordance with Table 2 of accepted standard [C-8(6)]; and

h) The parameters listed in (a) to (g) are valid for calculating glass thickness using the empirical relationship in **6.1.3**. For glass sizes larger than those mentioned, any recognized method of analysis may be used for design, in consultation with the manufacturer and the expert in the field.

6.1.3 *Empirical Relationship*

Empirical relation between the wind pressure, area of the glass panel and the required glass thickness can be used:

$$P_{\text{net}}.A = 200T^{k} \text{ (for } T \leq 6 \text{ mm)}$$

$$P_{\text{net}}.A = 200T^{k} + 1\,900 \text{ (for } T > 6 \text{ mm)}$$

where

P_{net} = Net design wind pressure as per **6.1.4**, in N/m^2;

A = Area of glass panel, in m^2;

T = Standard nominal thickness (SNT) of glass from Table 13, in mm; and

k = Constant from the Table 13.

Table 13 Value of k for the Corresponding Standard Nominal Thickness of Float Glass

(*Clause* 6.1.3)

***T*, mm**	3	4	5	6	8	10	12	15	19	25
k	1.683	1.732	1.753	1.765	1.57	1.578	1.583	1.579	1.569	1.569

6.1.3.1 *Glass supported on two opposite sides*

a) Normal and laminated glass panels supported on two opposite sides can be designed using following empirical relations:

1) For $T \leq 6$ mm :

$$b = \frac{4.39\,T}{\sqrt{\left(\frac{P_{net}}{P_f}\right)}}$$

2) For $T > 6$ mm :

$$b = \frac{4.22\,T}{\sqrt{\left(\frac{P_{net}}{P_f}\right)}}$$

b) Tempered/toughened panel supported on two opposite sides can be designed using following empirical relations:

   1) For $T \leq 6$ mm :

$$b = \frac{3.268\,8\,T}{\sqrt{\left(\frac{P_{net}}{P_f}\right)}}$$

   2) For $T > 6$ mm :

$$b = \frac{2.906\,9\,T}{\sqrt{\left(\frac{P_{net}}{P_f}\right)}}$$

where

b = span, in m; and

P_f = strength factors as in Table 14.

For insulated glass, thickness of only one glass pane shall be considered. If the glass panes are of different thickness, the minimum of the two thicknesses shall be considered.

For laminated glass, the thickness of PVB has not been considered. The value to be used is:

T = Standard nominal thickness —Thickness of PVB.

6.1.3.2 For non-linear analysis, specialist literature may be consulted for various shapes, sizes, and types of support conditions of glass.

6.1.4 *Determination of Design Wind Pressure*

Net design wind pressure (P_{net}) is an important parameter governing the thickness of glass to be used in the window panels. It depends on factors as given below:

a) Location of the building (wind zone),

b) Construction patterns around buildings (terrain category),

c) Topography of site,

d) Building plan and height, etc.

Net design wind pressure (P_{net}), may be defined using the following equation:

$$P_{net} = p_z . C_p$$

where

C_p= net pressure coefficient as per good practice [C-8(15)]; and

p_z = design wind pressure as per good practice [C-8(15)], in N/m^2.
$= 0.6\ V_z^2$

$V_z = V_b.k_1.k_2.k_3.k_4$

where

V_b = basic wind speed based on location {as per Fig. 1 of good practice [C-8(15)]};

k_1 = risk co-efficient factor;

k_2 = terrain factor;

k_3 = topography factor;

k_4 = importance factor for the cyclonic region; and

V_z = design wind speed, in m/s.

6.1.4.1 *Laminated/tempered/insulating glass*

To determine the thickness of laminated/ tempered/ insulating glass, the design wind pressure P_{net} is modified by dividing it with the strength or pressure factor P_f, dependent on the type of glass. The values of the P_f are given in Table 14.

Using the modified values of P_{net}, the thickness of other glass types can be obtained in accordance with **6.1.3**.

Table 14 Strength Factor, P_f

[*Clauses* 6.1.3.1(b), 6.1.4.1, 6.3.5 *and* E-1.1.1]

Sl No. (1)	**Glass Type** (2)	**P_f** (3)
i)	Normal (Annealed)	1.00
ii)	Laminated	0.80
iii)	Tempered	2.50
iv)	Insulated	1.50
v)	Heat strengthened	1.60
vi)	Wired	0.50

6.1.5 *Aspect Ratio* (AR_{max})

The design of the thickness using empirical relation in accordance with **6.1.3** shall be valid up to a limiting aspect ratio AR_{max}. The value of AR_{max} for different thickness (T) of glass is given in Table 15.

Table 15 Thickness and Corresponding AR_{max} Values (*Clause* 6.1.5 *and* E-1.1.1)

T, in mm	3	4	5	6	8	10	12	15	19	25
AR**max**	7.3	6.8	6.5	6.3	5.9	4.9	4.3	3.8	3.3	2.9

6.1.6 *Seismic Design*

6.1.6.1 *Seismic load* (*EQ*)

The design for seismic forces shall be performed in steps to establish upper and lower bound force and movement response parameters. In addition, the response of the structure sensitive to certain parameters such as the damping and the stiffness of the support points may be evaluated.

The principal design criteria for the seismic design are,

- a) Structure will remain elastic during the design seismic event.
- b) ‘Hangers’ will stiffen the cantilever ‘tree’ structure.
- c) ‘Hangers’ will not go slack.

6.1.6.2 *Architectural elements and utilities*

Depending on response sensitivity, architectural elements and utilities can be classified as deformation sensitive, acceleration sensitive, or both deformation and acceleration sensitive. Table 16 classifies non-structural elements according to their response sensitivity.

Table 16 Response Sensitivity of Architectural Component

(*Clause* 6.1.6.2)

v)	Canopies and marquees	P	—
vi)	Stairs	P	S

NOTES

1 P = Primary response
2 S = Secondary response

6.1.6.3 *Design seismic force*

Design seismic force on the architectural elements and utilities shall be calculated as per Part C ‘Structural Design, Section 1 Loads and Load Effects’ of this NBCS.

6.1.6.4 *Seismic relative displacement*

a) For two connection points on the same structure *A*, one at a height h_x, and other at a height h_y, seismic relative displacement shall be determined as:

$$D_p = \delta_{xA} - \delta_{yA}$$

D_p is not required to be taken as greater than $R(h_x - h_y)\frac{\Delta_{aA}}{h_{sx}}$

where

δ_{xA} = deflection at building level x of structure A due to design seismic load determined by elastic analysis, and multiplied by response reduction factor R of the building as per Table 9 of good practice [C-8(16)];

δ_{yA} = deflection at building level y of structure A due to design seismic load determined by elastic analysis, and multiplied by response reduction factor R of the building as per Table 9 of good practice [C-8(16)];

h_x = height of level x to which upper connection point is attached;

h_y = height of level y to which lower connection point is attached;

Δ_{aA} = allowable storey drift for structure A calculated as per **7.11.1.1** of good practice [C-8(16)]; and

h_{sx} = storey height below level x.

b) For two connection points on separate structures A and B, or separate structural systems, one at height, h_x and the other at a height, h_y , D_p shall be determined as:

$$D_p = |\delta_{xA}| + |\delta_{yA}|$$

D_p is not required to be taken as greater than

$$R\left(h_x \frac{\Delta_{aA}}{h_{sx}} + h_y \frac{\Delta_{aB}}{h_{sx}}\right)$$

where

δ_{yB} = deflection at building level y of structure *B* due to design seismic load determined by elastic analysis, and multiplied by response reduction factor, R, of the building as per Table 9 of good practice [C-8(16)]; and

Δ_{aB} = allowable storey drift for structure *B* calculated as per **7.11.1.1** of good practice [C-8(16)].

6.1.7 *Imposed Loads*

The uniform distributed load and point load is to be considered based on application and is to be selected in accordance with good practice [C-8(17)]. Appropriate uniform distributed load (UDL) and concentrated load are selected in accordance to good practice [C-8(17)] based on nature of building (for example, residential, institutional, industrial building, etc) and nature of activity under each building type.

6.1.8 *Load Contribution*

6.1.8.1 *Wind load*

The wind load is the effect of wind pressure which is dependent on the location, building height, topography and ground roughness factor. The wind speed is taken from good practice [C-8(15)] for the geographic location.

6.1.8.2 *Dead load*

In case of inclined sloped glazing, the dead weight of the glazing should be considered. In case of component of sloped glazing, the following corresponding component of the total glazing may be used:

a) Point load shall be applied as a uniformly distributed load over a circular area of 0.01 m^2;

b) For a glazed panel supported on all edges, the point loading shall be applied at the centre;

c) For free glazing edges, the point load shall be applied adjacent to the centre of the free edge; and

d) Ultimate limit state design wind pressure shall not be greater than 1.2 kPa. For greater design wind pressures, the glass shall be separately designed to withstand wind loading in accordance with **6.1.4**.

6.1.9 *Reference Chart Relating Wind Load, Maximum Allowable Area for a Thickness of Glass with Respect to Terrain Category*

Table 17 to Table 25 provides relation between design wind pressure and maximum allowable area for a thickness of glass with respect to specific terrain category. User may select the type of glass depending on the support conditions.

Specialist literature may be consulted for use of non-linear analysis.

NOTE — Specialist literature shall mean any national/international publication, codes or peer reviewed research papers on the topic.

The deflection at the centre of glass pane can be calculated using the formula in accordance to Annex D.

Typical model calculation to calculate thickness and determine wind load and deflection at the centre of the glazing is given at Annex E.

6.2 Installation

6.2.1 Basic installation requirements and materials used for glass are given hereunder:

NOTES

1 The provisions under this item do not include the use of other methods or systems for glazing, provided the alternate method or system can be demonstrated to satisfy the requirements for correctly supporting the glass within the frame, or glazing system.

2 Patent and other proprietary systems are not described/ covered here.

3 Installation technique for frameless glazing system is not covered here.

6.2.2 *Site Working and Glass Machining Operation*

6.2.2.1 Heat-strengthened and toughened glass shall not be cut or worked after heat treatment. All necessary cutting, drilling, notching and edge-working shall be carried out to correct dimensions prior to value addition to the glass, such as toughening/tempering/heat strengthening. The edges and surfaces of all glass types shall not be damaged during fixing.

6.2.3 *Dimensional Requirement*

The dimensions for edge clearance, edge cover, front and back clearance, rebate depth is selected in accordance with the requirements in **4.5.2**.

6.2.4 *Glazing Materials*

6.2.4.1 *Compatibility of materials*

A glazing material shall be used only when compatible with contiguous materials, including the rebate surface finish, setting or location blocks, distance pieces and glass type.

6.2.4.2 *Application of materials*

The application of glazing materials shall be in accordance with relevant/available Indian Standard or manufacturer's recommendations.

6.2.4.3 *Life expectancy of materials*

A glazing material shall only be used where its life expectancy (durability) has been established. The manufacturers' advice/guarantee should be sought for information regarding life expectancy.

6.2.5 *Setting Blocks*

The number and location of setting blocks shall be as shown in Fig. 14 and Fig 16. Generally, setting blocks shall be,

a) positioned at quarter points or not less than 30 mm from the corner, whichever is less;

b) the minimum width of each setting block shall be not less than the glass thickness; and

c) if a glazing bridge is used then the thickness of the glazing bridge can be added to the thickness of the setting block to achieve the minimum gap of 6 mm between the edge of glass and the framing member.

Setting blocks shall be located to equally support all panes of glass, and shall be fixed to prevent displacement during installation and service. The minimum length of each setting block (or two blocks side by side) shall be 25 mm in length for every square metre of glass area, with a minimum length of 50 mm. When wood is used as the material for setting blocks, only the seasoned ones should be used as green wood may shrink laterally (in the process of attaining equilibrium moisture content over a period of time) and result in loosened installations.

For example, for a 3.0 m^2 glass area, 3.0 mm × 25 mm = 75 mm long, that is, 75 mm is the length of each setting block.

Setting blocks shall be of resilient, load-bearing, non-absorbent, rot-proof, and material that is compatible with all other glazing materials conforming to available standards (if any) that may come into contact with the blocks.

NOTES

1 Setting blocks are used between the bottom edge of the unit and the frame to centralize and equally support both panes of glass.

2 Setting block width and location should not restrict water drainage.

3 Extruded rubber material with 80 to 90 shore A hardness is recommended.

4 Shaped setting blocks will be required for a glazing platform.

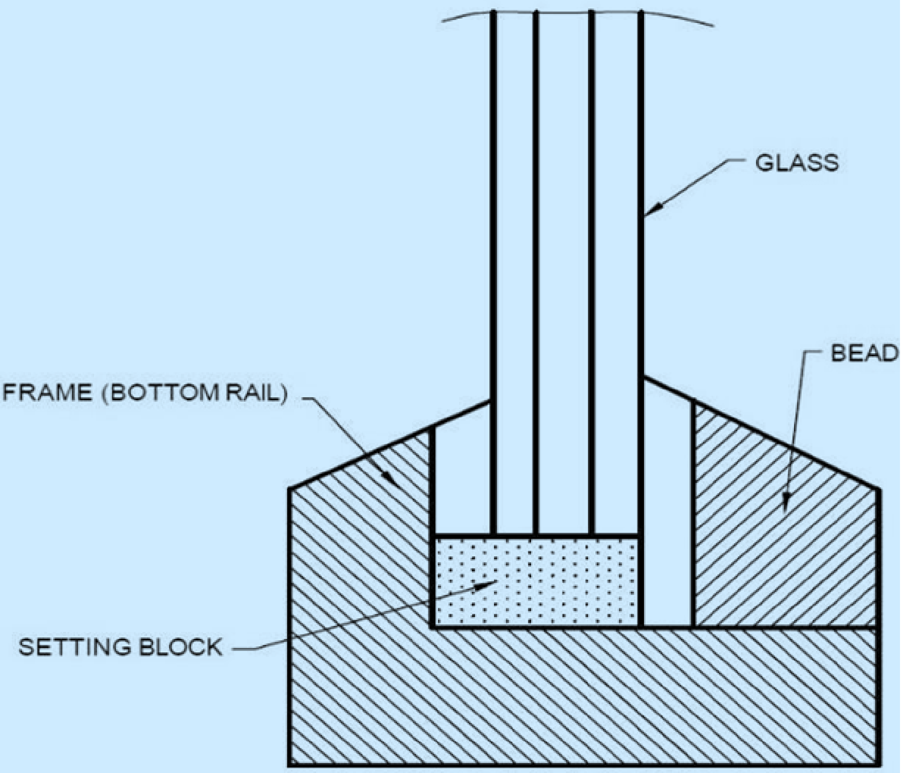

FIG. 14 POSITION OF SETTING BLOCK

6.2.6 *Location Blocks*

The number and position of location blocks shall be as shown in Fig. 15 and Fig 16.

Location blocks shall be,

a) of minimum of 25 mm in length;

b) at least as wide as the glass thickness;

c) positively located to prevent displacement in service; and

d) sufficiently resilient to accommodate movement within the frame, without imposing stress on the glass, and of resilient, non-absorbent material.

NOTES

1 Location blocks are used between the edges of the glass and the frame to prevent movement of the glass within the frame by thermal expansion or when the window or door is opened or closed. They are required to prevent the weight of the glass from causing the frame to become out of square.

2 Extruded rubber material with 55 to 65 shore A hardness is recommended.

NOTE : ■ LOAD BEARING BLOCK ▨ SPACER BLOCK

FIG. 16 NUMBER AND POSITION OF SETTING AND LOCATION/GLAZING BLOCK

6.2.7 *Distance Pieces*

Distance pieces, as shown in Fig. 17, used where required, shall be,

a) of resilient, non-absorbent material;

b) 25 mm long and of a height to suit the depth of the rebate and the method of glazing; and

c) spaced opposite each other, approximately 50 mm from each corner at intervals of not more than 300 mm.

The thickness shall be equal to the front and back clearance, to retain the glass firmly in the frame.

NOTES

1 Distance pieces are required to prevent displacement of glazing compounds or sealant by external loading, such as wind pressure.

2 Extruded rubber material with 55 to 65 shore A hardness is required.

6.2.8 *Rebates and Grooves for Installation*

Rebates, grooves and beads shall be cleaned and free from grease, moisture and other contaminants. All sealant surfaces shall be primed or sealed in accordance with the recommendations of the manufacturer of the glazing material.

The number and location of setting blocks and location blocks shall be as shown in Fig. 14 to Fig. 16, wherever necessary to maintain the requisite edge clearance. Each block shall support the full thickness of the glass.

6.2.9 *Glazing Beads*

Where used, glazing beads shall be capable of restraining the glass under all design forces.

6.2.10 *Structural Sealants*

Structural silicone shall be installed such that a full adhesive bond to the substrate is achieved. Application of structural silicone may require prior cleaning and or priming of the substrate.

Applied structural silicones shall not be installed adjacent to other materials that may be chemically incompatible with the structural sealant and cause a loss of adhesion or adverse chemical changes within the structural silicone that could lead to a loss of strength in the structural silicone. For guidance on the installation of structural silicone, reference to available standards/literatures may be made.

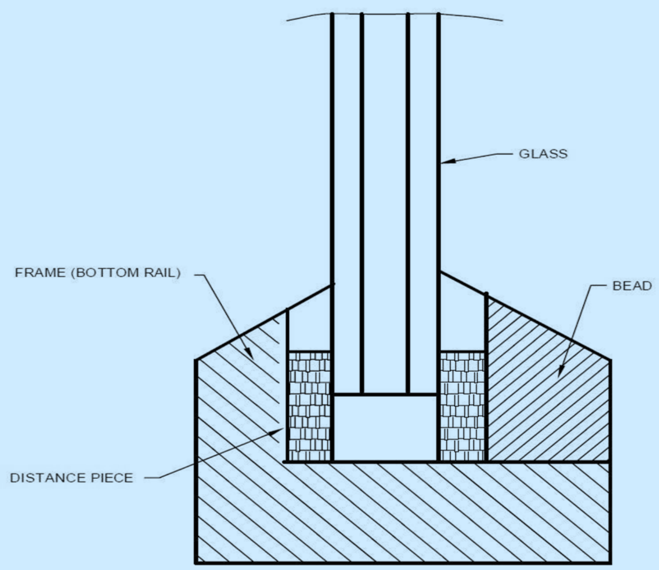

FIG. 17 POSITION OF DISTANCE PIECES

6.3 Design Criteria

6.3.1 *Frame Support Condition*

6.3.1.1 *Maximum area of glass panels subjected to wind loading*

The maximum span for a given standard nominal thickness of ordinary annealed, laminated, heat-strengthened and toughened glass for a given panel size shall be determined in accordance with **6.3.2**, **6.3.3** and **6.3.4** as applicable for the relevant support conditions. For heat strengthened laminated and toughened laminated glass, maximum allowable span shall be determined in accordance with **6.3.5**. For 3 mm monolithic annealed glass, the maximum area shall not exceed 0.85 m^2.

The minimum thickness of the nominal glass size shall be as per the accepted practice in accordance with Indian Standard specifications.

For laminated glass composites, the combined minimum thickness of the glass sheets may be used excluding the interlayer thickness. Alternatively, reference to specialist literature may be drawn for the same purpose.

6.3.2 *Rectangular Glass Supported on All Four Edges*

For rectangular glass supported on all four edges, the maximum area for the design wind pressure shall be determined using the corresponding tables provided for each type of glass. Linear interpolation may be used for any value in between those given therein while maintaining the aspect ratio.

6.3.3 *Rectangles of Glass Supported on Two Opposite Edges*

For rectangles of glass supported on two opposite edges, the maximum glass area for the design wind pressure shall be determined from Table 22 to Table 25 for ordinary annealed, laminated, toughened and heat-strengthened glass, respectively.

6.3.4 *Rectangles of Glass Supported on Three Edges*

For rectangles of glass supported on three edges, the maximum glass area shall be determined as for two-edge support spanning along the unsupported edge. Alternatively, basic engineering principles shall be adopted in determining the glass thickness for all applications where only three edges of the panel are supported.

NOTE — Butt glazing of adjacent panels in the same plane should not be considered as a support.

6.3.5 *Heat-Strengthened Laminated and Toughened Laminated Glass*

For heat-strengthened laminated and toughened laminated glass, the maximum span for a given standard nominal thickness for a given panel size shall be determined from Table 21 and Table 25, and Table 19 and Table 24, respectively with the design wind pressure being divided by the appropriate glass type factor, P_f (*see* Table 14), as applicable for the relevant support conditions.

6.3.6 *Serviceability Checks*

6.3.6.1 Glass complying to Table 17 to Table 25 are deemed to meet, the serviceability deflection limits specified. In the absence of any other specified values, the following values may be used for guidance.

6.3.6.2 *Maximum allowable deflection of framing members*

a) *For mullions*:
   1) Single height glazing — Span/175 or 19 mm, whichever is less.
   2) Double height glazing — For spans up to 4 110 mm, same as single height glazing; and for spans above 4 110 mm, the same shall be (Span/240) + 6.35 mm.

b) *For transoms*:
   1) Span/500 or 3 mm, whichever is the least for dead load.
   2) Span/175 or 19 mm, whichever is the least for wind load.

c) *Deflection at the centre of the glass*:
   1) Monolithic glass –Shortest span/60 or 19 mm, whichever is the least.

   2) Double glazed unit −Shortest span/90 or 19 mm, whichever is the least.

d) *Deflection at edge of the glass*:
   1) Shall be limited to 15 mm.

6.3.6.2.1 *Dielectric separation of dissimilar metals*

When the framing member for the glazing is aluminium and reinforcement is required to meet the deflection criteria, the reinforcement may be of aluminium or galvanized steel (red oxide coating being not recommended) with an insulating material between them at contact points. It is recommended to choose materials as close to each other in the galvanic series as possible.

6.3.7 *Ultimate Stresses*

The ultimate stresses for various types of glass are given in Table 26.

Table 26 Ultimate Limit State Design Stresses for Glass Subjected to Wind Loading

(*Clause* 6.3.7)

Sl No.	**Glass Type**	**Standard Nominal Thickness 'T'** mm	**Ultimate Limit State Design Stress at Given Location**	
			Away from Edge MPa	At Edge MPa
(1)	(2)	(3)	(4)	(5)
i)	Annealed	3	41.00	32.8
		4	38.99	31.19
		5	37.45	29.96
		6	36.2	28.96
		8	34.33	27.46
		10	32.8	26.24
		12	31.57	25.25
		15	30.15	24.12
		19	28.72	22.98
		25	26.96	21.57
ii)	Toughened	4	97.47	77.97
		5	93.61	74.97
		6	90.49	72.39
		8	85.82	68.65
		10	82.01	65.61
		12	78.91	63.13
		15	75.37	60.3
		19	71.81	57.45
		25	67.41	53.93
iii)	Heat strengthened	3	65.6	52.48
		4	62.38	49.9
		5	59.91	47.93
		6	57.91	46.33
		8	54.92	43.94
		10	52.48	41.99
		12	50.51	40.4

Table 26 Ultimate Limit State Design Stresses for Glass Subjected to Wind Loading

(*Clause* 6.3.7)

Sl No.	Glass Type	Standard Nominal Thickness '*T*' mm	Ultimate Limit State Design Stress at Given Location	
			Away from Edge MPa	At Edge MPa
(1)	(2)	(3)	(4)	(5)
iv)	Annealed laminated	5	37.73	30.18
		6	36.43	29.14
		8	34.41	27.53
		10	32.87	26.3
		12	31.62	25.3
		16	29.75	23.8
		20	28.23	22.58
		24	26.99	21.59

6.3.8 *Insulating Glass Units*

6.3.8.1 *Determining bite of structural silicone*

The structural bite requirement is directly proportional to the wind load and the dimension of glass. Higher the wind load and larger the dimensions of the glass are, the greater the amount of structural bite required. The controlling variables which affect the structural bite requirement are the maximum short span dimension of glass and the design wind load which the structural glazing system shall be designed to accommodate.

a) *Structural bite calculation for wind load and glass dimension*

$$\text{Minimum Structural Bite} = \frac{Glass\ Short\ span\ dimension \times wind\ load \times 0.5}{Maximum\ allowable\ design\ stress}$$

NOTES

1 Glass' short span dimension (SSD) is the shorter of the two dimensions (in m) of the rectangular glass panel.

2 Wind load is the maximum wind pressure, in Pascal, for a return period of 10 years based on local regulations.

3 The maximum allowable design stress for type of the structural sealant is selected as per manufacturer's recommendations.

4 The minimum structural bite shall be, not less than 6 mm for single glass and for double-glazed units (DGU) with equal glass thickness.

b) *Determination of thickness of structural silicone* — With a sealed IGU, there may be load sharing between the two panes of glass. If so, and if both panes are of the same thickness, the lateral load (*P*) is shared almost equally; thus the secondary seal bite is calculated as one half of that of the structural sealant bite, but should meet the minimum requirement. If of unequal thickness, the load shared by each pane will vary, depending on the difference in thicknesses. Further details are to be obtained from the manufacturer.

c) *Structural bite calculation for dead load*

$$Minimum\ Bite\ (m) = \frac{Weight\ of\ glass\ (kg)}{Perimeter\ of\ the\ glass\ (m) \times Seleant\ dead\ load\ design\ strength\ (kg/m^2)}$$

$$= \frac{\rho g T A}{Ps}$$

where

ρ = 2 500 kg/m^3 is the specific mass of flat glass corresponding to approximately of specific weight;

g = 9.81 m/s^2;

s = Allowable design stress for dead load (DL) for selected sealant considered for design, Pa;

T = thickness of the bite, m;

P = perimeter (if the horizontal frame members do not support the glass or deflect under the dead load of the glass, consider 2 times of its height only); and

A = area of glass panel, m^2.

6.3.8.2 *Maximum allowable span for glass and type*

Maximum allowable span is dependent on the thickness of the glass selected and type of glass used (for example annealed, toughened or heat strengthened glass). The maximum span is calculated in accordance with **6.1.9** (*see* Fig. 18 for details).

6.3.9 *Safety During Installation*

Glass and the coating layer (if any) should not be exposed to/in direct contact with aggressive materials such as acid, solvent, cement mortar, etc.

The fixing system of the panel should, in no case, cause shear stresses in the panel, and particularly the bonding interface between the glass sheet and the frame, either under the effect of external forces or due to differential expansion of components.

The protection of glass panel by means of a polyethylene sheet is recommended and shall provide ventilation for the glass in order to prevent thermal breakage.

Workers involved in the installation process shall be provided with adequate training and awareness about safety practices related to the handling and installation of glass panels. They shall be equipped with appropriate personal protective equipment (PPE), including but not limited to safety gloves, helmets, safety goggles, and footwear designed for the work environment, to minimize risks of injury during installation activities.

FIG. 18 TYPICAL STRUCTURAL GLAZING DETAIL

6.3.10 *Handling and Transportation*

6.3.10.1 *Transportation*

During the transportation of the flat glass (clear, tinted), coated glass (solar control and mirror), lacquered or painted glass the following methods (if other standard packaging specifications are not available) of storage, packing and interleaving shall be followed:

a) Flat glass shall be transported vertically;

b) Glass panes should not come into direct contact with each other by using appropriate interleaving such as powder or foam or paper. The lacquer opacified/enamel coated/screen printed glasses shall be separated by paper or foam; and

c) The packing and packing material shall be protected from water and if the glass is wrapped and sealed, the seal should remain closed until the product is used and precautions taken to not damage the packing while handling with a hoisting apparatus.

Workers involved in the transportation of glass shall be provided with adequate training on transportation safety practices. They shall be equipped with appropriate personal protective equipment (PPE), including but not limited to safety gloves, helmets, and safety footwear to minimize risks of injury during transportation activities.

6.3.10.2 *Handling*

During the handling of the flat glass (clear, tinted), coated glass (solar control and mirror), lacquered or painted glass, the following guidelines shall be followed:

a) Glass shall be handled with dry, clean gloves, specifically after washing to prevent stain marks on them;

b) Care shall be taken to avoid contact or friction of the coating or the opacified/ enamel/screen printed side with any rough surface or hard objects;

c) better practice is to handle glass with vacuum cups, and ensure that the vacuum cups and the glass are clean; and

d) It is recommended to keep the glass sheets clean if these are to be stored again before their processing or installation in the facade.

6.3.11 *Storage at Site*

To prevent staining, the storage area at site shall be,

a) a dry, well ventilated location at a sufficiently constant temperature;

b) protected from rain and running water;

c) protected from wide changes in temperature or humidity;

d) protected from alkaline material;

e) protected from direct contact of aggressive products such as corrosive vapours, acids, etc; and

f) glass panes are stored vertically on a soft surface such as wooden boards/battens.

6.3.12 *Storage after Cutting*

6.3.12.1 While stacking of coated glass/ mirror in the unpacked condition, the glass surface shall be facing towards the front (paint/coating backing towards the back).

6.3.12.2 Direct stacking of the mirror/coated glass one above the other should be prohibited and suitable inter-leaving material as mentioned in 6.3.10.1 should be used between two glass panes.

6.3.12.3 The support material for glass storage should not have affinity towards moisture absorption.

6.4 Fire Safety

6.4.1 This Section covers the requirement and selection of fire safety glass for buildings. General fire safety provisions for buildings may be drawn from Part F 'Fire and Life Safety' of this NBCS. It is important for any fire rated glass to provide sufficient amount of human impact safety feature even during fire or in general situations. The level of human impact safety of glass in buildings shall be in accordance with **7.1**. It is necessary that the fire rated system shall withstand the standard time-temperature curve during a fire test and shall give adequate time to the occupants for safe evacuation. This Section does not deal with the safety and security of people or goods in relation to risks of,

a) vandalism, riots, burglary or break in protection;

b) protection from explosion (terrorist attack);

c) natural disasters like earthquakes, cyclone, etc; and

d) plastic glazing, safety and security glazing, etc.

The requirements given here are minimum fire resistance requirements. In circumstances wherein the requirements of other Indian Standards exceed the requirements of this Section, the higher requirements shall be applicable.

6.4.2 *Glass for Fire Resistance*

6.4.2.1 Glazing system shall be so constructed, treated, or combined with other materials as to reduce loss of life or property during an event of fire, in comparison with ordinary sheet or flat glass, thereby preventing the passage of flame, hot gases, and smoke.

6.4.2.2 The following are the products in the scope of this Section that may be used for fire resistance provided they meet the requirements of accepted standard [C-8(18)]:

a) Wired fire resistant glass;

b) Glass-ceramic fire resistant glass;

c) Borosilicate fire resistant glass;

d) Thermally super toughened soda lime silicate fire resistant glass;

e) Laminated fire resistant glass;

f) Intumescent interlayer laminated fire resistant glass;

g) Gel-filled fire resistant glass; and

h) Low-E coated fire resistant glass.

6.4.2.3 *Testing procedures*

Any fire rated glazed building element needs to be tested as per accepted standard [C-8(19)]. The fire rating criteria of any building element is given in Part F 'Fire and Life Safety' of this NBCS.

6.4.2.4 *Identification of glass used for fire resistance*

a) All glass used for resisting fire shall conform to and preferably certified against available Indian Standards;

b) Since a fire resistant glass is not easily distinguishable from normal types of glass, it is imperative that every fire rated glass panel/unit should preferably have an indelible mark on all the panels/units of fire resistant glass showing the name of the manufacturer and the name of the product; and

c) Rating of the glass panel may also be provided, although the rating of glazing system is of primary concern.

The glass used for fire resistance should be in accordance with the requirements of Part F 'Fire and Life Safety' of this NBCS.

6.4.3 *Precautions*

6.4.3.1 Fire resistant glass alone shall not be enough to protect occupants from fire. Glass is only one component of the complete system.

6.4.3.2 Fire test report conducted for one application shall not be substituted for any other application. For example, a report for a partition shall not be used for a door application although the glass used and the fire ratings are the same. Similarly, approval in vertical orientation cannot be considered for acceptance in horizontal or inclined orientation.

6.4.3.3 The maximum glass size as mentioned in the test report should not be exceeded in practice with respect to the bigger linear dimension or area, unless otherwise supported with valid third-party tested evidence. The aspect ratio may be modified provided that none of the linear sides has a dimension greater than that of the largest dimension of originally tested glass.

6.4.3.4 The dimensions of the profile need to be the same as that tested. The sheet thickness of the profile can be increased with no change in the tested fire rating.

6.4.3.5 In case of any change in hardware, the new assembly should be retested as per the same standard and/or specification requirements. In the case of replacement of hardware, the same specification and make of the hardware can be used without retesting of the whole assembly.

6.4.3.6 Factors like edge cover, types of gaskets and type of fixtures also play a very vital role in achieving the fire performance of the building element. These have to be used and installed as per the test report/available standards.

6.4.3.7 Buildings having non-structural joints between floor slabs and external perimeter walls, pose an associated risk of smoke and fire traversing between adjacent floors is not uncommon. The use of suitable materials to seal such joints needs careful consideration towards fire safety as the same is part of the compartment/fire barrier.

All gaps between floor-slabs and facade assembly shall be sealed at all levels by tested system of equal fire rating as that of floor slab to prevent fire and smoke propagation from one floor to another. Accepted standard [C-8(20)] specifies the test method to determine the fire resistance performance of perimeter fire barrier joint system based on the length of time the system being tested to resist the fire before development of through openings or flaming and transmission of heat on the unexposed surface.

6.4.4 *Classifications of Fire Resistant Glass*

See **4** of accepted standard [C-8(18)].

6.4.5 *Cleaning and Maintenance of Fire-Rated Glazing System*

Routine maintenance and inspection are essential for fire rated glazing to ensure their optimal performance during a fire emergency. For more details in this regard, Part F ‘Fire and Life Safety’ of this NBCS may be referred.

7 SAFETY RELATED TO HUMAN IMPACT, ANTI-FALLOUT, WINDOW RESTRICTOR FOR CHILDREN AND DYNAMIC WIND RESTRAINT

7.1 Safety Related to Human Impact

7.1.1 *General*

The provisions herein are limited to the behaviour of glass when subjected to various kinds of human impact, precautions against risk of fall and falling glass. Conditions outside of ‘human impact’ are not covered under the scope of this Section.

This Section does not assume that the glass used in accordance to this Section will not break under all human impact conditions, rather,

a) it will not break under most likely forms of human impact; and

b) even if it breaks, the likelihood of cutting or piercing injuries will be minimised by virtue of the protection given to the glass, or by the limited size, or by the fracture characteristics of the glass.

Further, this Section does not deal with the safety and security of people or goods in relation to risks of,

a) vandalism, riots, burglary or break in protection;

b) fire arm protection;

c) protection from explosion (terrorist attack);

d) natural disasters like earthquakes, cyclone, fire, etc; and

e) plastic glazing material, safety and security glazing, etc.

In circumstances wherein the requirements of any referred standard(s) exceeds the requirements of this Section, the higher requirement shall be applicable.

The use of this Section shall also be in conformity with all other relevant standards on fire safety, structural stability, natural disasters, safety and security, etc in force.

7.1.2 *Safety Glass*

Glazing material that are constructed, treated, or combined with other materials shall reduce, in comparison with ordinary sheet/ float/ plate glass, the likelihood of injury to persons by objects from exterior sources or by these safety glasses when they may be cracked or broken.

The following are the products in the scope of this Section that may be used in safety glazing provided they meet the conformity requirements of accepted standard [C-8(7)]. Safety glass according to this Section shall be of following types:

a) Toughened safety (tempered) glass; and

b) Laminated safety glass.

7.1.2.1 All safety glasses shall meet the requirement of tests specified in accepted standard [C-8(7)].

7.1.2.2 In atria where there is no impact loads above 10 m, suitable toughened glass is adequate. *See* **4.2.9**, in case of use of glass fins as a structural member.

7.1.3 *Critical Location*

Where any glazing is within 1.5 m above the floor level of a building, it is considered likely to be subjected to human impact and hence, shall comply with the human impact safety requirements of this Section. Safety glazing should also be used,

a) where there is danger of falling infill glass material(s) from overhead glazing;

b) the danger of falling due to a change in floor level; and

c) in case of balustrades, stairs and floors.

Based on typical accidents in glazed buildings, certain locations in buildings are found to be more vulnerable to human impact than others. Some of such critical locations are given below and shown in Fig. 19, where necessary precautions have to be followed:

1) in-and-around doors, low windows;

2) door side panels;

3) panels mistaken for a doorway or opening;

4) panels at low levels in walls and partitions;

5) bathrooms;

6) building associated with special activities, for example, gymnasia, enclosed swimming pools, etc;

7) schools and child care facilities; and

8) nursing homes and care facilities for the aged and infirmed.

Suitable precautions should be taken to reduce the injuries that can result from glass breakage by,

i) selecting glass of a suitable type, thickness and size;

ii) enhancing a person's awareness of presence of glass by making glass visible (manifestation of glass); and

iii) minimizing manual handling of large pieces of glass during installation.

Based on the above, a comprehensive suggestion on type of glass to be used at different critical location/cases is provided in Table 27 for information.

	 GLASS RESIDUAL PROTECTION GLASS WINDOW Hs > 0.75 m	 GLASS FACADE Hf ≤ 1.5 m Hs < 0.75 m GLASS	 Hf ≥1.5 m Hs < 0.75 m Hs < 0.75 m Hf ≥1.5 m	 GLASS SHELTER SKYLIGHTS	 GLASS RAILING
Type of glass	Any glass[1)]	Safety glass[2)]	Safety glass[2)]	Laminated safety glass	Laminated safety glass

Table 27 (*Continued*)

Examples	Residual protection is the safeguard provided to avoid the impact of human being on glass. It is provided on the side of the glass where there are chances of human impact. It can be achieved by providing protection in the form of a sill structure or transom, chair rail or grill work inside.	a) Doors b) Side panels c) Curtain walls d) Glazed area e) Doors in bathroom 1) Fully framed 2) Partially framed 3) Frameless f) Facade g) Windows h) Internal partitions and doors j) External facade and doors on ground floor, above floor with terrace outside.	a) Curtain walls b) Facade c) Spandrels d) High activity area e) High risk area f) To avoid risk	a) Roof (Skylights) b) Ceilings c) Bus shelters d) Floors e) Stairs f) Sloped facade	a) Balustrades b) Balcony c) Railings

[1] Safety glass is not mandatory.

[2] Laminated safety glass is preferred.

NOTES

1 'H_f' corresponds to height of fall of human being or glass in case of change in level and 'Hs' corresponds to the sill height with reference to floor height.

2 In case of mirror glazing, it should conform to the requirements of other safety glasses unless it is fully backed by a solid material.

3 In Case 2 and Case 3, if the smaller dimension of the pane is 250 mm or less and its area is 0.5 m^2 or less, glass other than safety glass may be used, provided that its nominal thickness is not less than 6 mm (applicable to vertical glazing).

4 Toughened or laminated safety glass should meet respective test requirements as given in respective Indian Standards.

5 The effective toughened safety glass thickness and/or laminated safety glass configuration shall be determined case by case with regard to,

a) other solicitations (wind load, snow load, dead load, and human load);

b) the overall dimension (length, width of surface);

c) the aspect ratio of the glass; and

d) the glazing fixing type (framing, bolted system, structural system, etc).

Table 27 (*Concluded*)

6 Precautions against chances of injuries due to broken glass falling on people include:

- a) Broken annealed glass falling on people can cause grievous or even fatal injuries; hence it is recommended to use safety glass in locations other than defined in Case 1 where the risk of people getting hurt by falling glass is high.
- b) Toughened safety (tempered) glass has a safe breakage pattern, as it breaks and disintegrates into small and relatively harmless particles. However, thick toughened glass particles may stay interlocked, and fall as lumps of these multiple particles and can cause a minor or medium injury mainly due to the weight of the cluster.
- c) Laminated safety glass shall generally not fall out of fixing. However, where laminated glass with both glasses toughened, used for horizontal or sloped glazing, in case of failure of both toughened glasses, it may crumble as a blanket and fall out of fixing. This factor needs to be considered while designing horizontal and sloped glazing. Further, when the slope is acute, inner pane facing the floor should be laminated; and when the slope is obtuse, the outer pane facing the ground/floor should be laminated and all obtuse angle sloped glazing shall be continuously capped for safety reasons.
- d) Any broken glass in any glazing should be removed immediately on breakage.
- e) Strength of the glazing system should be such that it has the ability to hold glass in place and prevent it from falling out as a whole.
- f) For over-head applications like skylights and canopies, for the safety of maintenance workers and people underneath, the broken laminated glass shall be capable of sustaining a load of 100 kg for a minimum duration 30 min.

7 In case of external laminated glass facades, openable portions have to be left at regular distances for firefighting and smoke exhaust. This portion should be of toughened (safety tempered) glass and clearly indicated by suitable visible marking. *See also* Part F ‘Fire and Life Safety’ of this NBCS.

8 If insulating glass unit (IGU) is used in situations mentioned in this Section, then one of the following shall apply:

- a) If IGU is installed in areas subjected to human impact on either side, then both the panes of the unit shall meet the requirements of this Section.
- b) In situations where access is restricted to one side of the unit, then only the accessible side should meet the requirements of this Section.

9 Awareness of presence of glass may be by making visible manifestation.

10 For specific provisions relating to smoke evacuation, Part F ‘Fire and Life Safety’ of this NBCS may be referred.

7.1.4 *Manifestation* (*Making Glass Visible*)

7.1.4.1 Presence of glass in a door, side panel or a panel capable of being mistaken for a doorway or opening, which is not made apparent by transoms, colonial bars, door frames, large door handles, stall or other components of glazing system, should be made apparent by some form of manifestation. Decorative treatment, such as being opaque, or patterned are the other common manifestation options.

The manifestation employed should be of a sufficient size to make it immediately obvious. The manifestation should preferably be permanent, for example etching of the glazing; alternatively, if applied materials are used, they should be durable and not easily removed.

7.1.4.2 A band or marking may not be required, where any one of the following apply:

a) Width of the glass is not greater than 500 mm at any part (this applies to overall panel assembly – not individual glass pieces as in faceted glazing).

b) Glass is provided with at least one fixed glazing bar, firmly attached to the styles to locate and protect each face of the glass. At least one transom (glazing bar) shall be located with its upper edge not less than 500 mm and its bottom edge not more than 1 000 mm above the floor level. The glazing bar shall have a face of width 40 ± 3 mm; and

c) Alternatively, patterns may be used as an acceptable form of marking provided it meets the other criteria in this Section.

7.1.5 *Identification*

All safety glasses shall be procured from certified manufacturers and the product shall conform to relevant Indian Standards and shall carry all relevant information through the approved label/permanent (indelible) markings on the glass surface.

7.1.6 *Test Requirements*

7.1.6.1 Safety glass shall confirm to all the test requirements mentioned in the accepted standard [C-8(7)].

7.1.6.2 *Mechanical strength*

The required mechanical strength values (*see* Table 28) apply to quasi-static loading over a short time like wind loading relate to 5 percent probability of breakage at the lower limit and 95 percent confidence intervals.

If the glass satisfies the relevant impact test performance requirements (or fragmentation test for toughened glass), in addition to all other appropriate tests mentioned in available Indian Standards or as listed in Table 28, these materials can be classified as safety glass.

Table 28 Minimum Mechanical Strength Required for Fully Toughened Glass

(*Clause* 7.1.6.2)

Sl No. (1)	**Type of Glass** (2)	**Mechanical Strength** N/mm^2 (3)
i)	Float (clear/ tinted/ coated/ mirror)	120
ii)	Enamelled flat (based on enamelled surface in tension)	75
iii)	Patterned glass	90

7.2 Anti-Fallout

The following shall apply:

a) For all open out windows in buildings up to 5 storey height (< 15 m) anti-fallout secondary safety device is optional; and

b) For all open out windows in buildings more than 5 storey height (> 15 m) anti-fallout secondary safety device is mandatory.

7.2.1 In the case of a fall out due to the sash getting completely disengaged from the hinges/stay arms/restrictors, the anti-fallout device shall be capable of withstanding the self-weight of the sash. The drop height for the test shall be 100 mm. Design and testing for the mechanism to take into consideration jerk load with a factor of safety 2.0. Both static tensile test and a drop test with the mechanism installed in a window to be carried out to validate the compliance of the hardware to the design requirements.

7.3 Window Restrictor for Children

For windows which are non-emergency exits, projected top hung window, parallel opening window, vertical sliding hung window, side hung window and pivot window (except when used as an access door), the window restrictor shall be located such that the clear opening shall not exceed 100 mm (for human life safety especially for anti-fallout for children). When a force of 250 N is applied in opening condition to any part of the sash a sphere of 100 mm shall not pass through any part of the opening. Key releasable window restrictor can be used for the purpose of cleaning/maintenance. The side hung opening shall be restricted to be used in low rise buildings {< 15 m, *see* good practice [C-8(15)]}. For buildings above ≥ 15 m height, projected top hung or parallel opening with an opening restriction of 100 mm shall be used.

NOTES

1 For fire access panels/window, the local authority regulations will be applied and same will supersede the above.

2 The above requirement of window restrictor for children is mandatory for residential apartments and optional for commercial establishment. However, it is recommended to limit the opening to 100 mm for commercial establishments as well, especially for high rise buildings.

7.4 Dynamic Wind Restraint

This is applicable for open out windows in buildings more than 5 storey height (> 15m) and where the dynamic wind load is high due to the adjacent structures or terrain. Installed hardware shall be capable of self-locking the open window upon first time closure of the window due to wind conditions; in order to avoid fatigue failure on the hinges and stays. The mechanism can be releasable either using existing handle or additional release trigger. Design shall be to serviceability conditions.

8 GLAZING SYSTEM

8.1 The provisions relating to glazing system are covered hereunder. The details and procedure for selection, design, fabrication, installation, testing and maintenance of glazing system and its materials, considering the performance factors, including structural, seismic, acoustic insulation, fire resistance and energy efficiency are covered here under.

For classification of glazing system, reference may be made to **6** of accepted standard [C-8(14)].

8.2 Design and Selection

The design considerations and parameters for the design and selection of a glazing system and the components involved, along with its associated materials used in buildings are given below.

8.2.1 *Design Considerations*

Table 29 covers the various design considerations for glazing systems.

Table 29 Design Considerations

(*Clause* 8.2.1)

Sl No. (1)	Design Considerations/Criteria (2)	Reference Standards (3)
i)	**Structural aspects and parameters:**	
	a) Design load and wind load classification	As per good practice [C-8(15)] and accepted standard [C-8(14)]
	b) Other Loads — Live load, dead load, etc	As per good practice [C-8(21)]
	c) Air infiltration/Exfiltration and its classification	As per accepted standard [C-8(14)]
	d) Deflection	As per **6** and accepted standards [C-8(14)] and [C-8(12)]
	e) Seismic performance	As per **6.1.6** and good practice [C-8(16)]
	f) Water tightness and its classification	As per accepted standard [C-8(14)]
	g) Glass thickness	As per good practice [C-8(22)]
	h) Structural sealant	As per **4.4.1**
	j) Frame/profile specifications:	
	1) Aluminium	As per accepted standard [C-8(12)]
	2) uPVC	As per accepted standard [C-8(23)]
	3) Steel	As per accepted standard [C-8(24)]
	k) Hardware and fixing	As per **5.4** of accepted standard [C-8(12)]
ii)	**Energy aspects and parameters:**	
	a) Window to wall ratio	As per relevant guidelines/best practices (Handbook on ‘Sustainability in Buildings’)
	b) Building orientation	
	c) Window to floor ratio	
	d) Thermal performance (roofs and fenestration):	
	1) U-Value of glazing	As per relevant guidelines/best practices (Handbook on ‘Sustainability in Buildings’)
	2) Solar heat gain Co-efficient (SHGC)/Solar factor of glazing	
	3) Visible light transmittance (VLT)	
	4) Glass – Thermo – Optical properties: U value, solar heat gain co-efficient, visible light transmittance, internal and external (heat and light) reflectance and transmittance, shading co-efficient	As per **5**

Table 29 (*Concluded*)

Sl No. (1)	Design Considerations/Criteria (2)	Reference Standards (3)
	e) Lighting	As per Part D 'Building Services, Section 1, Lighting and Natural Ventilation' of this NBCS
iii)	**Safety**	
	a) Safety related to human impact	As per **7.1**
	b) Window restrictor for children	As per **7.3**
	c) Anti-fallout	As per **7.2**
	d) Fire safety	As per **6.4** and Part F 'Fire and Life Safety' of this NBCS
	e) Security glazing:	
	1) Bullet resistance	As per **9**
	2) Ballistics resistance	As per **9**
	3) Resistance to explosion	As per **9**
	4) Burglar resistance	As per **9**
iv)	**Acoustics parameters**	
	a) Airborne sound insulation	As per accepted standard [C-8(25)
	b) Impact sound insulation	As per accepted standard [C-8(26)]

8.2.2 *Design Parameters*

To achieve the performance criteria, care should be taken so that components in the system are selected and designed for the following parameters, such that the necessary performance criteria is met both individually and as a system:

a) Loading;

b) Deflections and allowable stress;

c) Movements;

d) Impact resistance;

e) Acoustic and sound insulation; and

f) Energy performance.

8.2.2.1 *Loading*

Wind load, live load, dead load, load combinations as per good practice [C-8(27)], seismic load as per good practice [C-8(16)], and other consequential loading may be considered.

8.2.2.2 *Deflections and allowable stress*

The deflection of framing members, members supporting brittle materials, metal panels, glass panels and the allowable stress shall be in accordance with 6.3.6.2. The allowable stress shall be in accordance with good practice [C-8(27)].

8.2.2.3 *Movements*

The glazing system (and its framing elements) shall be able to accommodate the movements caused due to wind loads, seismic loads, live loads, dead load deflection, thermal expansion and contraction of members, slab deflection, etc.

8.2.2.4 *Impact resistance*

Any glazing (in the glazing system) within 1 500 mm above the floor level of a building is considered likely to be subjected to human impact and hence, shall comply with the human impact safety requirements given in 7.1.

8.2.2.5 *Acoustics and sound insulation*

The recommendations on acoustics and sound insulation given in Part D 'Building Services, Section 4 Acoustics, Sound Insulation and Noise Control' of this NBCS shall be applicable.

8.2.2.6 *Energy performance*

The recommendations on the principal energy performance characteristics of the glazing system shall meet the provisions given in 5.

The primary characteristics required in general are reducing thermal losses and solar gains. For additional reference to visible light transmittance (VLT), solar heat gain coefficient (SHGC) and thermal transmittance (U-factor) features, relevant guidelines/best practices (Handbook on 'Sustainability in Buildings') may be referred.

8.2.3 *Types of Structural Frame Materials*

For the framed/semi-framed systems, materials such as aluminium, stainless steel, uPVC and timber, which are commonly employed are given hereunder.

8.2.3.1 *Aluminium alloy*

Extruded aluminium alloy used for structural framing members, shall be fabricated from the most appropriate grade of alloy complying with the relevant standard(s). The thickness of the aluminium sections should be in accordance with structural and hardware fastening requirements and shall be capable enough to meet the design requirements and satisfy the performance requirements.

Such extrusions in framing members and trims shall preferably be extruded aluminium grade 6063-T5, 6063-T6, 6060-T66, similar or stronger. Where 6063-T5 is to be used in shaped structures, supporting structural calculations particularly the stress criteria be ensured. Extrusion alloy 6061 or 6105 are commonly used for higher strength. Aluminium brackets shall be extruded aluminium grade 6061-T6 or approved equivalent. All aluminium alloys used as extruded rods/bars, tubes and profiles shall be compliant with accepted standard [C-8(28)].

Sheets and plates may be obtained from the following alloys of aluminium along with their primary characteristics:

a) 1100 — A low strength alloy suitable for applications requiring a high degree of formability.

b) 1135 — Brighter finish when anodized.

c) 3003 — General purpose sheet alloy with fair mechanical properties and excellent formability, but susceptible to structural streaking when anodized (noticeable in large flat areas).

d) 5005 — Excellent workability, weldability and corrosion resistance.

e) 5052 — Slightly better mechanical properties and excellent corrosion resistance and weldability.

Other alloys can be used provided that they meet the required physical properties and the specified performance requirements.

8.2.3.2 *Stainless steel*

Mullions, panels, fascia, column covers, windows, doors, trim, roofing, gutters, flashing, hardware and other items where minimum maintenance is anticipated, shall be of austenitic stainless steels of Type 301, 302 and 304 complying with accepted standard [C-8(29)] and employed for their mechanical properties as they are highly corrosion resistant for all normal exposures.

For interior decorative applications, where regular maintenance will be provided, Type 430 may be used as it has lesser corrosion resistance properties. For external applications like in coastal regions where maximum resistance to corrosion is required, stainless steel shall be of Type 316. Particular attention shall be paid to the direction of the rolling grain on self-finished stainless steel components where the finish is aesthetically important. All screws, nuts, bolts, washers, self-tapping screws and other fastenings, including those used for the hardware, shall be of stainless steel Type 304, 316, 430 complying with accepted standard [C-8(29)]. Type 316 based steel fasteners, etc shall be preferable when they are used in coastal regions on the exposed side.

8.2.3.3 *uPVC*

A relatively flexible material, PVC which is internally reinforced with steel or aluminium to give it the required strength and stiffness may also be used. The inherent ability to make a variety of profiles, easier maintenance, corrosion resistance and heat resistance when used may be considered when choosing uPVC sections.

8.2.3.4 *Timber*

Timber frames are relatively stiff and particularly treated timber combined with good design and workmanship give an acceptable life. They are adopted for their inherent thermal insulation property, light weight and improved sound insulation. Tenderness to absorb moisture, if not carefully treated prior to use can lead to possible rotting or even warping resulting in air and water infiltration and regular painting and maintenance are the factors to be considered while choosing timber as the framing material.

8.2.4 *Surface Finishes*

The commonly employed surface finishes are listed hereunder:

a) *Aluminium frames* — The main types of aluminium frame coatings are as follows:
   1) Anodized finish,
   2) Powder paint finish, and
   3) PVDF coating.

b) *Steel frames* — Surface finish on stainless steel frames plays a major role in its resistance to corrosion and hence it is an important design aspect to be clearly specified. The types of surface finishes listed here shall be in accordance with applicable relevant standards:
   1) Mill,
   2) Ground,
   3) Brushed,
   4) Polished,
   5) Bead blasted,
   6) Electro polished,
   7) Coloured, and
   8) Patterned.

Electro polishing of steel frames shall be done in accordance with available standards.

c) *Timber frames* — The function of finishes on timber is two-fold, first to improve the durability of the frame and second to add to the aesthetics. Unfinished, unprotected timber weathers as a result of gradual changes to its physio-chemical structure brought about by temperature and moisture content variations. The finishes may be of the following types:

   1) *Conventional opaque systems* — Water and solvent borne;
   2) *Natural finishes* — Semi-transparent and opaque; and
   3) Water repellent preservatives, wood primers, undercoats and finishing coats (gloss, semi-gloss, flat and low sheen).

Based on the application, the appropriate type of finish shall be chosen.

8.2.5 *Types of Anchorages*

Post-installed anchors are used primarily to join the mullions and transoms to the beam or slab through an appropriate bracket. The most common types of post-installed anchors are torque controlled expansion anchors and adhesive anchors. The selection of the appropriate anchor depends on the load requirement. For details on the types of post-installed anchors, reference may be made to good practice [C-8(30)].

There are different factors which influence the selection of anchors and to ensure proper performance of the anchor during its service life. These include:

a) *Diameter* — The following parameters shall be calculated for the selection of the anchor diameter:

   1) Dead load acting on the anchor;
   2) Live load incident to the anchor (wind load- tensile or shear);
   3) Weight of bracket, aluminium channels and other associated components; and
   4) Performance against earthquake load.

b) *Length* — The overall length of the anchor is based on the effective embedment length into the concrete and the total thickness of the glazing components which have to be fastened to the base material. Insufficient embedment length shall lead to pull-out failure of the anchor;

c) *Material* — Stainless steel and galvanized iron are the two main types of materials used in the manufacturing of anchors. The selection of anchor material shall be based on the location of the anchors, considering factors such as interior or exterior application, exposure to weather, or enclosed conditions;

d) *Coating* — The following type of coating shall be used based on the specific environmental condition met with:

Sl No. (1)	*Environmental Condition* (2)	*Coating to be Used* (3)
i)	Particular influence of moisture	Zinc plated
ii)	Occasional exposure to condensation and in coastal areas/slightly corrosive	Hot-dip galvanized
iii)	Heavy condensation/corrosion and in coastal areas:	
	a) areas with high corrosion risk	Stainless steel (SS 316)
	b) risk of exposure to corrosion is medium	Stainless steel (SS 304)

e) *Load Direction* — Based on the orientation of the anchor, they are incident to shear loading, tensile loading and combined loading;

f) *Base material* — The material characteristic of the base material (concrete) also plays a major role in avoiding failure in the anchorage. The material shall be of suitable grade, have minimum thickness, shall be properly cured and have the necessary compressive stress. Unless otherwise mentioned by the concerned structural engineer, the concrete shall be considered as cracked for all design purposes. Reference shall be made to good practice [C-8(30)] for more details in this regard;

g) *Anchor spacing and edge distance* — Anchor spacing is the centre to centre distance between the anchors. Edge distance is the distance from the centre of the anchor perpendicular to the respective edge of the concrete member. Reference shall be made to good practice [C-8(30)] for more details in this regard;

h) *Effective embedment depth* — It is the effective depth which actually transfers the forces passing through the anchor into the concrete. Reference shall be made to good practice [C-8(30)] for more details in this regard;

j) *Environmental condition* — Environmental conditions like temperature, humidity, salinity, etc will affect the performance of the anchors and may lead to pre-mature failure. Hence, careful selection of the material and coating should be done when selecting anchors which are to be installed in location subjected to adverse environmental impact such as coastal region; and

k) All the anchors shall be designed as per the recommendations of good practice [C-8(30)].

8.2.6 *Hardware Materials*

The material, geometry and finish of all the hardware materials shall be as per the requirement and should not affect the performance of the glazing system. All materials and finishes shall be as per relevant Indian Standards and tested before installing into the system in accordance to relevant Indian Standards.

8.3 Fabrication

8.3.1 *Factory*

The manufacturer shall ensure that proper internal control and documentation including records of test results performed be maintained about the production. The above shall enable quality assurance of the materials and process involved.

NOTE — For fabrication tolerance of aluminium systems, reference shall be made to **6** of accepted standard [C-8(12)].

8.3.2 *Handling of Materials on Site*

The following lists among others, the important features to be considered:

a) All materials shall be handled by workers who have been provided appropriate training and awareness on the techniques to handle the materials and shall operate with a full set of personal protection equipment (PPE);

b) Large glass panes or panels shall be handled with vacuum cups. Care shall be taken to ensure that the vacuum cups and the glass are perfectly clean. An additional rope or belt is recommended to support the dead load as a fall arrestor;

c) All materials shall be handled with dry, clean, gloves and shall not come in contact with rough surfaces or hard objects, in order to avoid scratches, dents or breakage; and

d) Labels and marking shall not be put on the coated side of glass, and any relative movement of the coating with the next glass pane shall be avoided.

8.3.3 *Transportation and Logistics*

While transporting materials from vendor to factory, within the factory, to and from surface finish coater, finished goods to site and moving finished goods at site, care should be taken to ensure the following:

a) Finished surface is adequately protected with a protective tape which can be easily removed without leaving any residue;

NOTE — Most protective tapes either peel off or adhere to the substrate when exposed to UV for more than three months.

b) Suitable blocking, edge protection, crating, etc are done to avoid dents and gouges;

c) Hardware is secured and not damaged in transit;

d) Material is adequately secured in the truck/container especially when the goods are sent as loose container load (LCL) or partial shipment, avoiding any damages;

e) Lifting equipment shall be adequately engineered for capacity, safety and balance (especially when units are very heavy);

f) Suitable 'A' frames or customized transport support shall be used; and

g) Recommendations from glass supplier towards the use of protective film shall be followed.

8.4 Installation

8.4.1 *Site Survey of Building*

a) Measuring the elevation width and height, ascertaining the grid pattern including position of vision and spandrel frames, the levels of concrete and masonry in x, y and z axis, checking and recording the presence of any difference in plumbness of jambs, beam and column fascia and steel structures are the key activities necessary in deciding the final fabrication measurements;

b) Levelling (setting x-axis, common sill level for all elevation and adjustment in bracket depth) and surveying (measuring x-axis distance and setting the width and height for all elevation) are involved in the process of site survey of building. The key processes are listed below:

   1) *Processes in levelling*:

      i) The sill bottom level of all the glazing elevations are to be checked by fixing a common benchmark and the reading should be recorded at minimum one metre distance;

      ii) After taking the reading the highest and lowest point can be located and a decision on the common level of all glazing elements made;

      iii) The benchmark shall be a permanent mark, using oil paint mark in form of upside triangle;

      iv) The levels of all beam bottoms and up stand, if any, coming across the glazing elevations at all floors are to be measured; and

      v) Any other point that can affect fabrication drawings is to be noted.

   2) *Processes in surveying*:

      i) The total width shall be measured using a theodolite and recorded at one plane;

      ii) It shall be cross checked by measuring existing column to column (at other plan) distance; and

      iii) The two end point RCC shall be measured for plumbness. If any difference is observed, the readings of first two steps shall be adjusted.

8.4.2 *Installation Tolerance*

The effect of installation tolerance is vital for any type of glazed system to perform as per the requirement and the specified performance. For structural glazing, the installation tolerances shall be strictly followed in order to assure that the sealant joint opening meets the specified minimum and maximum joint opening dimensions.

NOTE — For installation tolerance of aluminium systems, reference shall be made to **5.2** of accepted standard [C-8(14)].

8.4.3 *Good Installation Practices*

The good practices involved in installing a glazing system have been categorized hereunder.

8.4.3.1 *Anchorage*

The anchor installation shall be undertaken by installers who have been adequately trained by the manufacturer to install the specific type of anchor. The installer should be familiar with the correct installation procedures and ensure that the correct drilling and setting tools are available for the proper installation of the anchor.

For details with respect to the right installation procedure, reference shall be made to good practice [C-8(31)].

8.4.3.2 *Sub-structures*

a) In order to avoid physical contact with the panels and frames during sealant application, which might cause adhesion loss, powder-free latex gloves shall be used during panel placement;

b) Proper alignment and setting out of the sub-frame is critical in ensuring the ease of operation of the window/door;

c) Anchor/bolt heads and joints between external wall and sub-frame should be sealed with sealant for effective water tightness;

d) Prior to fixing the main frame, the sub frame should be checked for any physical damages and any damaged sub-frame should be repaired or replaced;

e) Setting out of the sub-frame should also be verified before the installation of the main frame; and

f) The sub-frame shall be properly cleaned before assembly as dust and debris accumulated in the sub-frame could affect the alignment and fixing of the main frame and may also cause blockage to the weep holes, resulting in overflow of any incidental water into the interior.

8.4.3.3 *Sealants*

a) All components (glass and framing member such as aluminium) receiving the structural glazing silicone sealant shall be wiped thoroughly with a clean cloth dampened with a cleaner recommended by the manufacturer, and immediately followed by a dry wipe, using clean cloth;

b) All surfaces once cleaned/primed shall be handled carefully so as not to contaminate the surface;

c) The substrates shall be kept free from moisture, condensation, dust and other impurities;

d) An application temperature range of + 10 °C to + 40 °C (or as specified by the manufacturer) is recommended and shall be adhered to;

e) Substrate temperatures in excess of + 50 °C will adversely affect curing process and also the adhesion of the sealant to the substrate;

f) Minimal time shall be taken for cleaning, placement and sealing of panels since environment conditions at job site cannot be controlled;

g) Temporary fasteners may be used to keep the joints stable during the curing process of the sealants and they shall be removed only after complete cure and adhesion has been achieved by the sealant;

h) Tooling of the sealant shall be done with light pressure, within 5 to 10 min, before a skin forms on the sealant;

j) The use of wet tooling aids such as soaps and solvents shall be avoided. Dry tooling is appropriate;

k) Masking tape shall be used in ensuring neat straight-line application and avoiding smears;

m) The masking tape shall be removed immediately after tooling has taken place and before the sealant starts to cure;

n) The general recommendation for the application of structural sealant required for a 4-sided system, bonding the glass to the aluminium frame should be done in a factory atmosphere;

p) Complete quality control process with respect to surface preparation, storage, sealant application and quality check are to be implemented in the factory with full traceability. In most cases sealant manufacturers have quality requirements and documentation process related to warranties which need to be followed; and

q) *In-situ* application may be required for 2-sided system, retrofit, repair and small areas in a facade. Sealant manufacturers should be contacted to get specific recommendation on sealant application for *in-situ* application.

8.4.3.4 *Installation*

The framing and fixing system of the panel should, in no case, cause shear stresses in the panel, either under the impact of external forces or due to differential expansion of components. The following shall be taken care of:

a) All framing shall be checked prior to glazing to assure that the opening is square, plumb and secure so that the uniform sealant bite, face and edge clearances are maintained;

b) Inspection of all butt and mitre joints shall be carried out and if found open, they shall be sealed using sealants prior to glazing;

c) Minimum edge clearances shall be maintained between glass and sash, as mentioned by the manufacturer;

d) Setting blocks shall be used to support the glass unit which shall prevent the addition of stress applied on the structural tensile bead due to the self-weight of glass; and

e) Adhesion tests shall be performed by the contractor/agency at the beginning and during the installation process.

8.5 Testing

8.5.1 *Laboratory Testing*

The glazing system is subjected to various adverse environmental conditions and impacts during its service life. A properly designed and installed glazing system may be able to resist any major damage to its stability or performance under any condition within its effective life time. The glazing system and its component materials shall be tested for the required parameters and performance.

8.5.2 *Field/On-Site Testing*

Testing of the glazing system as a whole unit in site (the field) subject to loads and effects such as water infiltration, wind (air) infiltration, acoustic insulation, fire insulation, thermal performance, structural performance, etc may be carried out for specific cases as mutually agreed to between the parties concerned, to ensure homogeneity.

The Table 30 lists the tests to be carried out for glazing systems including curtain walls, windows, skylights, sliders, doors, etc. The frequency of these tests shall be mutually agreed upon by the parties concerned.

Table 30 Testing of Glazing Systems including Curtain Walls, Windows, Skylights, Sliders, Doors, etc

(*Clause* 8.5.2)

Sl No. (1)	Test Parameters (2)	Testing Method (3)
i)	Air permeability	As per accepted standard [C-8(32)]
ii)	Water penetration — Static air pressure difference	As per accepted standard [C-8(33)]
iii)	Water penetration — Dynamic air pressure difference	As per accepted standard [C-8(34)]
iv)	Standard operating forces	As per accepted standard [C-8(35)]
v)	Window and doors resistance to repeated opening and closing	As per accepted standard [C-8(36)]
vi)	Wind resistance for curtain walls, windows, sliders and skylights	As per accepted standard [C-8(37)]

Table 30 (*Concluded*)

Sl No. (1)	Test Parameters (2)	Testing Method (3)
vii)	Structural load test (100 percent design wind load)	As per accepted standard [C-8(37)]
viii)	Structural proof load test (150 percent design wind load and seismic force, if applicable)	As per accepted standard [C-8(37)]
ix)	Seismic racking test	As per Annex F
x)	Water penetration — Field	As per accepted standard [C-8(32)]
xi)	Thermal performance of windows, doors and shading devices — Detailed calculations	As per accepted standard [C-8(38)]
xii)	Calculation of thermal transmittance — Numerical method of frames	As per accepted standard [C-8(39)]
xiii)	Mechanical tests for standard windows and door height windows	As per accepted standard [C-8(40)]
xiv)	Fire resistance of perimeter fire barrier joint system	As per accepted standard [C-8(20)]
xv)	Fire resistance tests — Door and shutter assemblies	As per accepted standard [C-8(41)]
xvi)	Fire resistance test for glass walls	As per accepted standard [C-8(42)]
xvii)	Fire resistance test for doors with glass panes, openable glass windows and sliding glass doors	As per accepted standard [C-8(43)]
xviii)	Forced entry security glazing	As per accepted standard [C-8(44)]
xix)	Bullet resistant glass	As per accepted standard [C-8(45)]
xx)	Acoustics — Sound insulation	As per accepted standard [C-8(25)] and [C-8(26)]
xxi)	Blast resistant security glass	As per **9.4.3**

8.6 Maintenance

8.6.1 *Maintenance Infrastructure*

Regular maintenance of the building facades plays an important role in the holistic building maintenance. The access systems shall provide sufficient approach which enables all parts of the facade to be reached safely for the purpose of cleaning, inspection and maintenance and also offer high work efficiency to the maintenance workers, without also hindering the aesthetics of the building. The provisions of relevant guidelines/best practices (Handbook on 'Asset and Facility Management in Buildings') may also be referred.

The means of access and supporting infrastructure should be established at the design stage so that the loads are properly envisaged for.

Facade access requirements come in many varieties and may present challenges. Powered access cradles for facade access, cleaning of the glass directly from the ground, hoists based access and window based cleaning/access from inside the building are some of the common techniques employed. Recently, access techniques using ropes have been used for facade access and are generally considered to be safe, provided the workers have been trained and are using all the correct safety equipment and precautions.

In nearly all cases, facade access and maintenance requires a worker to be exposed to working at height with its associated risks. Therefore, use of height safety equipment, anchor point attachments (like the fall restraint or fall arrest system) and those given below should be employed:

a) *Roof guardrails* — When choosing equipment for working at heights, collective protection like roof guardrails may also be considered. Roof guardrails ensure that all users are protected from falling without the need for specialised training and/or equipment. They also eliminate the need for rescue procedures to be put in place. Roof guardrails are available as fixed, free standing, straight upright, cranked upright or collapsible; and

b) *Fall arrest systems and fall prevention cable systems* — Fall arrest systems allow safe access to roof areas for maintenance and inspections to be carried out by workers. Users of the fall arrest systems require wearing of full body harnesses and attachment to the cable/fall arrest system via a lanyard (rope) and shuttle device which allows them to walk the full length of the system without having to detach from the system. Fall arrest systems shall be of horizontal, overhead, sloping and vertical lifeline type and shall comply to the relevant/available standards.

Depending on the project requirement, the maintenance infrastructure shall consist of the following systems:

1) *Roof trolley/Cradles* — Fixed or adjustable jib, telescopic jib and cradle with pantograph.
2) *Rail systems* — Hooked, anchored, turntables and rotary plates.
3) *Other systems* — Additional winches for glass replacement and parking positions/lifting platforms.

8.6.2 *Maintenance of Materials*

The glazing system and the associated materials require a suitable degree of maintenance, if they are to fulfil their intended working life. Early detection of defects can mitigate expensive repairs or replacement later. The degree of inspection and maintenance required will depend on the type of glazing system and its intended design life.

8.6.3 *Common Practices for Maintenance*

The common principle maintenance practices to be followed shall be as given below:

a) When using the cleaning equipment or carrying out maintenance on the exterior of the building, the risk to personnel and property, prior to the start of work shall be assessed at first;

b) Where applicable, qualified personnel to carry out routine or complex maintenance shall be employed;

c) Power supplies may need to be isolated prior to maintaining electrically operated equipment such as motors to opening vents, roller blinds to atrium roof and main entrance pass doors;

d) While accessing the external facade, fall arrest systems shall always be used even while working in the house cradle;

e) Manufacturer's instructions shall be followed when using cleaning fluids and shall not be mixed up with drinking water or the like. To deal with instances of contact with eyes, skin, etc necessary eyewash arrangement and first aid equipment shall be in place;

f) Loosened fixing or bolts shall be identified, reported and attended to immediately, and shall never be tampered with;

g) Unauthorized loosening or removing of the fixings may prove dangerous and can result in structural damage and displacement of the system;

h) When lifting equipment such as hoists and sucker machines are used, it shall be ensured that they are capable of lifting the loads required. Further, the recommended safe working loads of any equipment shall never be exceeded;

j) When handling any insulation of firebreak material, it shall be ensured that gloves, goggles and masks are worn as fibrous materials (if any) may cause irritation;

k) Prior to the commencement of work involving glues or sealants (particularly in confined spaces), manufacturer's advice/special instructions shall be adhered to before exposing the product to air. Such materials shall preferably be worked with, in a well-ventilated area;

m) In the case of coated glass, the following precautions shall particularly be adhered to:

   1) Any scratching shall be avoided as this may penetrate the surface of the coating and cannot be repaired;
   2) Any excessive mechanical treatment shall be avoided as this might remove the coating in localised areas;

3) Contact with metal objects shall be avoided; and

4) Use of chemicals that may attack the surface and damage it irreparably shall be avoided.

9 SECURITY GLASS

9.1 This clause covers the requirements and selection criteria for security glass in buildings. The general methodology for selecting types of security glass shall be in accordance with **4**. It is essential for any security glass in addition to its required function to provide adequate human impact safety features. The level of human impact safety for glass in buildings shall be in accordance with **7.1**. Furthermore, the security glass shall meet the classification standards to which it has been tested, ensuring the safety and security of occupants and goods. This clause deals with the safety and security of people or goods in relation to risks of,

a) vandalism, riots, burglary or break in protection;

b) protection from firearm shooting;

c) protection from explosion (terrorist attack); and

d) protection from ballistic attacks.

The requirements given below pertain to glass used in areas with high-security needs. In circumstances wherein the requirements of other Indian Standards exceed the requirements of this clause, the higher requirements shall become applicable.

9.2 Glass and Related Material for Security

Glass used for security purpose are laminated glass with different combination of glass panes including annealed glass, heat strengthened glass, toughened glass, and interlayers (including polyvinyl butyral, ethylene vinyl acetate, plastic sheets, polycarbonate sheets, etc) in accordance with **4**.

9.3 Selection Criteria

The selection criteria is based on the threat levels/risks (firearm shooting, ballistic attacks, explosion, burglary, etc) and stages of protection as per the requirements of the buildings and the user.

9.4 Testing procedures

9.4.1 *Burglary Resistance of Glazing Systems*

The framing member along with its hardware and glass should comply for the burglar resistance requirements as a whole. The glass to be used should comply with the testing requirements of accepted standard [C-8(44)]. The following Table 31 lists the minimum requirements for various resistance classes of glazing.

Table 31 Minimum Requirements for Glazing

(*Clause* 9.4.1)

Sl No. (1)	Resistance Class (2)	Minimum Resistance Class of Glazing as per Accepted Standard [C-8(46)] (3)
i)	RC 1 N	Any glass (test is for hardware manipulation for entry)
ii)	RC 1	P4A
iii)	RC 2 N	Any glass (test is for hardware manipulation for entry)
iv)	RC 2	P4A
v)	RC 3	P5A
vi)	RC 4	P1B
vii)	RC 5	P2B
viii)	RC 6	P3B

If a glass unit with a higher security level is used within the specimen used for the tests, it may not be possible to assess the use of glass units with a lower grade within those products without conducting further tests. This is because higher grades of glass can increase the rigidity of the product.

The following Table 32 lists the criteria for the selection of the resistance class (offender type, offender behavior, location, risk and recommendation for use).

Table 32 Criteria for the Selection of the Resistance Class

(*Clause* 9.4.1)

Sl No.	**Resistance Class**	**Expected Offender Type, Suspected Offender Behaviour**	**Recommended Place of Use of the Burglar-Resistant Component**		
			A Residential properties	B Commercial properties, public properties	C Commercial properties, public properties (High risk)
(1)	(2)	(3)	(4)	(5)	(6)
i)	RC 1 N/ RC 1	Components of resistance class RC 1 N/RC 1 provide basic protection against attempts to break in with physical force such as kicking in, jumping, shoulder slamming, pushing up and tearing out (mainly vandalism). Components of resistance class RC 1 N/RC 1 only have a low level of protection against the use of lever tools	If burglar resistance is required, the use of resistance class RC 1 N/RC 1 is only recommended for building components where no direct access (not ground level access) is possible		
ii)	RC 2 N/ RC 2	The occasional offender tries in addition, to break open the component with simple tools such as screwdrivers, pliers and wedges. (RC 2 N is only recommended for building components where no direct attack on the glazing used is to be expected)	Average risk attack on the glazing used is to be expected	Average risk	Not applicable

Table 32 (*Concluded*)

Sl No.	**Resistance Class**	**Expected Offender Type, Suspected Offender Behaviour**	**Recommended Place of Use of the Burglar-Resistant Component**		
			A Residential properties	B Commercial properties, public properties	C Commercial properties, public properties (High risk)
(1)	(2)	(3)	(4)	(5)	(6)
iii)	RC 3		High risk	The offender tries in addition, to break open the component with a second screwdriver and a crow bar.	Not applicable
iv)	RC 4	The experienced burglar uses in addition, tools such as a hand saw, heavy hammer, axe, chisels, and a battery-powered drill.	Not applicable	Not applicable	Low risk
v)	RC 5	The experienced burglar uses in addition, electric tools such as an electric drill, jig saw, or sabre saw and an angle	Not applicable	Not applicable	Average risk
vi)	RC 6	The experienced burglar uses in addition, heavy-duty electric tools, such as a heavy-duty drill, jig saw or sabre saw and angle grinder	Not applicable	Not applicable	High risk

NOTES

1 This table is only an approximate guide. Expert advice, for example, from the local police advice centres, is essential. The assessment of the risk should be on one's own responsibility, taking into account the location of the building (protected/unprotected), use and the value of the goods inside. In case of high risk, tested and certified burglar alarm systems should be used in addition.

2 When selecting burglar-resistant elements of resistance classes RC 4 to RC 6, it should be noted that when selecting such elements in escape and rescue routes, the use of tools by the fire brigade is made more difficult and shall therefore be taken into account.

3 External sockets, for example, in the hallway, in the garden or in the patio (open space) area should be de-energized to prevent their use by the burglar.

In addition, parties to agreement may mutually decide on testing arrangement based on specialist literature.

NOTE — Specialist literature may be EN 1630 : 2021 'Pedestrian doorsets, windows, curtain walling, grilles and shutters - Burglar resistance - Test method for the determination of resistance to manual burglary attempts'.

9.4.2 *Bullet Resistance Glazing*

The framing member along with its hardware and glass shall comply for the bullet resistance requirements as a whole. The glass to be used should comply with the testing requirements of accepted standard [C-8(45)].

The testing of framing member shall follow the same parameters of spall, no spall as well as threat levels (*see* Table 33) described in accepted standard [C-8(45)] but with penetration points in the framing member. Glazing system classification will hold good only if both the framing member and glass complies. In case, either glass or frame achieves a lower classification, then the whole glazing system shall be classified to the lower class that has been achieved.

Table 33 Threat Levels

(*Clause* 9.4.2)

Sl No. (1)	**Threat Level** (2)	**Ammunition** (3)	**Bullet weight** g (4)	**Bullet Type** (5)	**Strike Velocity** m/s (6)	**Distance of Impact** m (7)	**No. of Strikes** (8)	**Remarks** (9)
i)	1	9 mm × 19 mm	7.4 to 8.2	FMJ/Pb	430 ± 15	5 ± 0.5	5	–
ii)	2	7.62 mm × 39 mm	7.45 to 8.05	FMJ/ MSC	710 ± 15	10 ± 0.5	5	–
iii)	3	7.62 mm × 51 mm	9.4 to 9.6	FMJ/Pb	838 ± 15	10 ± 0.5	5	plus compliance with Threat Level 2
iv)	4	5.56 mm × 45 mm	3.5 to 4.0	FMJ/(SI + Pb)	890 ± 15	10 ± 0.5	5	plus compliance with Threat Level 3
v)	5	7.62 mm × 39 mm	7.45 to 8.05	HSC	700 ± 15	10 ± 0.5	5	plus compliance with Threat Level 3
vi)	6	7.62 mm × 54 mm	10.3 to 10.5	API	830 ± 15	10 ± 0.5	1	–
vii)	Special (*see* Notes)	Any other requirement by the user. Complete details of ammunition shall be stored for future upgradation of this NBCS						

NOTES

1 For special threat levels, the bullet velocity specified for the test should be representative of that developed by the weapon and ammunition, preferably at the higher end of the range of possible velocities. The range selected should be sufficient to enable the bullet flight to stabilize.

2 FMJ/Pb = Full metal jacket – Lead core, FMJ/MSC = Full metal jacket – Mild steel core, HSC = Hard steel core, API = Armour-piercing incendiary.

9.4.3 *Blast Resistance Glazing*

The framing member, along with its hardware and glass, shall collectively comply with the blast resistance requirements specified in Annex G. Glazing system classification will hold good only if both the framing member and glass complies. In case either glass or frame achieves a lower classification, then the whole glazing system shall be classified to the lower class that has been achieved.

The test ammunitions specified in this NBCS represent the most frequently faced threats and are classified into six threat levels given in Table 34.

Table 34 Classification, Charge (TNT/Equivalent Charge) Mass, Distance (*d*) and Height of Burst (HOB)

(*Clauses* 9.4.3, G-4.7 *and* G-4.8)

Sl No. (1)	**Threat Level** (2)	**TNT/Equivalent Charge Mass** kg (3)	**Distance of Explosive Charge (TNT/Equivalent Charge) from the Test Specimen (*d*)** m (4)	**Height of Burst (HOB)** m (5)
i)	1	2	4.5	0
ii)	2	3	5.0	0.5 ± 0.05
iii)	3	3	3.0	0.5 ± 0.05
iv)	4	12	5.5	0.8 ± 0.05
v)	5	12	4.0	0.8 ± 0.05
vi)	6	20	4.0	0.8 ± 0.05
vii)	Special		Any other requirement by the user.	

The structural integrity of glass system test specimen is evaluated by visual inspection in the following categories of outcome:

a) *Category A* — No damage to the glass and the frame of glass system;

b) *Category B* — The entire system is bent or deformed leading to the overall jamming or dis-functioning of the system;

c) *Category C* — Formation of cracks on the glass system and no damage to the frame of the glass system;

d) *Category D* — Cracking/shattering of different glass layers and damage to frame of the glass system;

e) *Category E* — Formation of splinters from the glass system or the frame within a distance of 3 m. The size of perforations in the glass or the frame shall not be more than 10 mm; and

f) *Category F* — Total collapse of the glass or frame of the glass system or both.

ANNEX A

(*Clause* 2.15)

TEST METHOD FOR ASSESSING CURTAIN WALLS AND STOREFRONT SYSTEMS UNDER INTER-STOREY DRIFT CONDITIONS

A-1 OBJECTIVE

This test method provides a means of evaluating the performance of window wall, curtain walls and storefront systems when subjected to specified horizontal displacements in the plane of the wall. This test is applicable to window wall, curtain wall and/or storefront mock-ups consisting of supports and components, with glass panels fixed across more than one storey (hereinafter referred to as exterior wall systems). This test method is applicable to window systems only when included as part of a full-size wall mock-up. This test method describes the apparatus and the procedure to be used for displacing a specimen horizontally. The displacement cycle time is not limited and is intended to duplicate the inter-storey displacement rates associated with dynamic building sway or seismic or wind events. This test shall be applicable for seismic Zone IV and Zone V. However, depending upon application and for tall structures, it shall be performed for other seismic zones as well.

This annexure does not support to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this test method to establish appropriate safety, health, and environmental practices and determine the applicability of regulatory limitations prior to use.

A-2 TERMINOLOGY

A-2.1 Lateral Movement — A sideway displacement of a structure or part of the structure.

A-2.2 Test Specimen — The test element is referred to as the specimen. The test specimen for a wall shall be of sufficient size to determine the required performance of all typical parts of the wall system.

A-2.3 Specimen Area – The area calculated from the overall dimensions of the test specimen.

A-2.4 Floor Height – Height of one floor of the sample to be tested.

A-2.5 Horizontal Displacement – The relative displacement of the curtain wall in the horizontal direction when subjected to horizontal movement.

A-2.6 Window Wall – It sits between floor slabs and are anchored at the sill and head.

A-3 APPARATUS

A-3.1 The description of the apparatus in this section is general. Any suitable apparatus arrangement during the laboratory accreditation process is permitted.

A-3.2 The displacement(s) may be accomplished using hydraulic or pneumatic cylinders or jacks of sufficient load and stroke capacity, or mechanical devices, such as ratchet pulleys or a chain hoist.

A-3.3 Test chamber members that are representative of the building structure shall be designed to accomplish the specified displacement(s). This may be done through a system of sleeves, fixtures, pins, or any system capable of accomplishing the displacement(s) directed by the specifier.

A-3.4 The displacement measuring system shall be accurate to within 1.5 mm (0.06 inch).

A-4 CALIBRATION

All test equipment shall be calibrated periodically, at least once every six months. Calibration should be done from an accredited laboratory providing traceability of calibration to national standards established through a chain of calibration certificates.

A-5 TEST SPECIMEN

A-5.1 The exterior wall system test specimen shall be of sufficient size and configuration to determine the performance of all typical parts of the exterior wall system. A minimum of three vertical bays in two adjoining floors of the exterior wall system shall be tested. If the wall has inside and/or outside corner, one set of corner bays shall also be included in the testing specimen. For glazing that is anchored within the floor/storey such as windows, doors, sliders and horizontal strip facade, the test specimen can be of a single floor.

A-5.2 All parts of the exterior wall system test specimen shall be full size, using the same materials, type of glass, detailing, methods of construction and anchorage as those used on the actual building.

A-5.3 The test chamber structure shall simulate the main structural supports of the actual building. However, the test chamber and/or support structure may differ from the actual building, as required, to perform the required displacement. For multi-storey mock-ups, the test chamber shall be constructed so that the anchorage at the simulated floor structure at an intermediate level of the test specimen is moveable in the horizontal direction(s). For single storey mock-ups, the test chamber shall be constructed so that the anchorage at the top or bottom is moveable in the horizontal direction(s).

A-5.4 The test laboratory shall minimize unintended torsional or flexural movements of chamber and/or support structure that could affect test results.

A-6 PROCEDURE

A-6.1 Prior to conducting the displacement tests, the test specimen shall be, at a minimum, characterized for serviceability by conducting air leakage and water penetration tests. The air leakage and water penetration tests shall be conducted at the differential pressures specified for the project.

A-6.2 Conduct Specified Displacement Test(s)

A-6.2.1 Test chamber elements representing the primary building structure shall be displaced to produce the specified movements. Each test shall consist of minimum three full cycles. A cycle is defined as a full displacement in one direction, back to the originating point, full displacement in the opposite direction, and back to the originating point (*see* Fig. 20).

A-6.2.2 Hold the specimen at displaced position not more than 60 s at each direction.

A-6.2.3 An inspection to be conducted during and after every cycle and recorded.

A-6.2.4 At the conclusion of the test, technicians and witnesses shall visually inspect the mock-up for evidences of failure.

A-6.2.5 The test agency shall record all areas of visual distress, such as disengagement, metal distortion, sealant or glazing failure, gap between framing members, or permanent deformation.

A-6.2.5.1 If glass breakage occurs during displacement tests, the test agency personnel shall carefully examine the test specimen and document the extent of this glass breakage.

A-6.2.6 Elements representing the building structure shall be displaced in a manner and method as determined by the test agency and may be subject to review by the design professional. Movement shall be parallel to the primary plane of the wall.

A-6.2.7 Changes in displacement direction(s) shall allow for movement of equipment, stops, measuring devices, etc. The test agency shall displace the chamber elements in a manner that is not intended to induce sudden acceleration and deceleration.

A-6.2.8 Additional cycles and/or displacement direction(s) may be specified by the design professional. The chamber elements shall be returned to their nominal position after completion of each cycling test, before further tests are conducted.

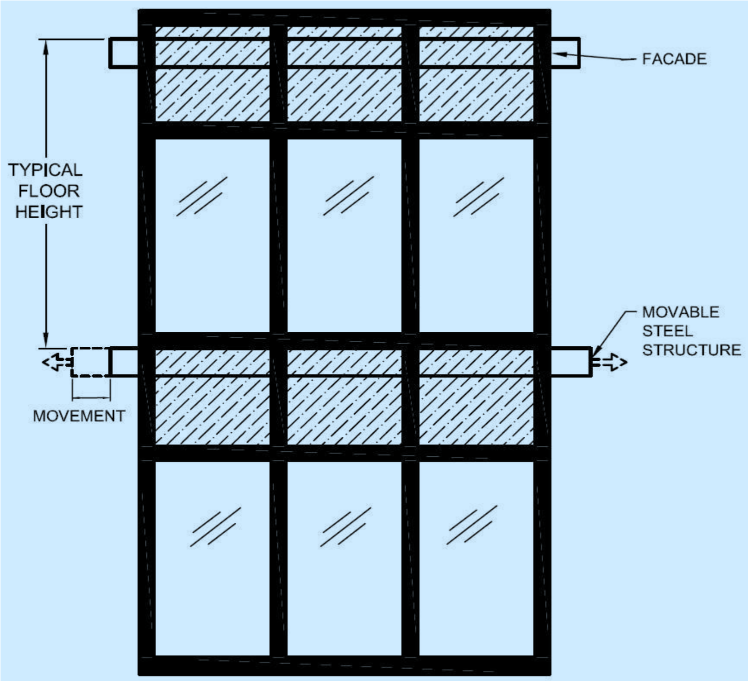

FIG. 20 ILLUSTRATION OF MOVABLE STRUCTURAL ELEMENTS IN CURTAIN WALL SYSTEMS UNDER INTER-STOREY DRIFT CONDITIONS

A-6.2.9 The elastic design displacement shall be as provided by the building engineer of record, determined by elastic analysis or other suitable method for a specific building. The displacement shall be measured at the movable floor element, not at the test specimen. For multi-storey mock-ups, the displacement between levels may vary due to different storey heights. If unspecified in contract documents, for testing, elastic design displacement in each direction shall be H/500, for curtainwall systems that span from floor-to-floor and primarily accommodate movement through racking or tipping.

A-6.3 Serviceability tests for air leakage as per accepted standard [C-8(47)] and static water penetration as per accepted standard [C-8(33)] may be conducted after the static elastic design displacement tests. The air leakage and static water penetration tests should be conducted at the pressures specified for the project.

A-6.4 The displacement shall be measured at the movable chamber member that represents the floor element, not at the test specimen or its anchorage.

A-7 CRITERIA

A-7.1 The project specifications shall state detailed performance criteria for the windows, window wall, curtain wall or storefront system. If detailed performance criteria are not included in the project specification, the criteria outlined in this test method shall be utilized.

A-7.2 Unless otherwise specified, an exterior wall system test specimen subjected to the elastic design displacement test shall be considered as passing the inter-storey drift provisions of this test method if the specimen meets the following criteria:

a) No visible damage to framing or trim components or assemblies is allowed.

b) No glass breakage or glass fallout is allowed.

c) Full disengagement of gaskets or weather seals is not allowed at any location.

d) Any gap between framing members shall be notified.

e) Air infiltration and static water penetration resistance shall remain within specified allowable limits without adjustments or repair for serviceability conditions.

NOTE — If any of air infiltration or static water penetration test fails, then seismic test has to repeated before proceeding with air infiltration or static water penetration retests.

f) No wall components may fall off.

NOTE — If an inter-storey drift (1.5 × storey height) test is conducted, the results shall be recorded and mutually agreed upon with the specifier. In this case, compliance with the above failure criteria is not required.

A-8 REPORTING

The information to be duly reported after testing are given hereunder.

A-8.1 General

Testing agency, date and time of test, and date of report.

A-8.2 Specimen Details

A-8.2.1 *Specimen Description*

Manufacturer, model, operation type, materials, and other pertinent information; description of the locking and operating mechanisms if applicable; glass thickness, type and method of glazing; weather seal dimensions, type, weep holes, and material; and crack perimeter or specimen area, or both.

A-8.2.2 *Drawings of Specimen*

Detailed drawings of the specimen showing dimensioned section profiles, framing location, panel arrangement, installation and spacing of anchorage, weather stripping, locking arrangement, hardware, sealants, glazing details, weep holes, drainage path detail, and any other pertinent construction details. Any modifications made on the specimen to obtain the reported test values shall be noted.

A-8.3 For window and door components, a description of the locking and operating mechanism.

A-8.4 Identification of glass thickness and type and method of glazing.

A-8.5 Test Parameter

A-8.6 List of Equipment Used

List the equipment name, identification number and calibration validity of all the equipment used at the time of testing.

A-8.7 Test Observation

A visual record of the test observations.

A-8.8 Photographs or drawings of the test chamber and the wall system test specimen mock-up indicating location of measuring devices and movement devices.

H-8.9 Compliance Statement

A statement that the tests were conducted in accordance with this test method, or a complete description of any deviation from this test method. When the tests are conducted to check for conformity of the specimen to a particular performance specification, the specification shall be identified.

A-9 INFORMATION OF DESIGN LOADS

In order to design and detail exterior wall systems and their attachments to meet the inter storey drift requirements, the design load shall be as per good practice [C-8(48)].

Inter-storey drift can result from either seismic loads or by wind loads.

ANNEX B

(*Clauses* 5.1, 5.2.11 *and* 5.3.3.6)

MINIMUM PERFORMANCE REQUIREMENT OF GLAZING FOR EXTERIORS

B-1 The panel size design of the exterior glass for the building is done in accordance with this Section considering the effect due to wind load, other imposed load and seismic design. The type of glazing to be installed is determined considering human safety in **7.1**.

In the determination of the energy and thermal performance of the glazing, the three compliance approaches prescriptive in nature, defines the minimum glazing/glazing system requirement to be met.

The prescriptive values are specified with respect to the geographic climatic zone and glazing area of the building.

B-2 BUILDING FENESTRATIONS

The fenestration may comply with the maximum glazing area weighted on *U*-value and solar factor as given in relevant guidelines/best practices (Handbook on 'Sustainability in Buildings').

The window wall ratio (WWR) is defined by the total fenestration area to the total gross area of the building envelope which is limited to 70 percent. The corresponding minimum visible light transmission is given below. For fenestration area greater than 70 percent, a reference may be made to other specialist literature.

Sl No. (1)	*WWR* (2)	*Minimum Visible Light Transmission* Percent (3)
i)	0 to 0.3	27
ii)	0.31 to 0.4	20
iii)	0.41 to 0.5	16
iv)	0.51 to 0.6	13
v)	0.61 to 0.7	11

B-3 WEATHER PERFORMANCE

Air infiltration from the fix litres shall be permitted within 1.5 $m^3/h.m^2$ and from operable sash 2 $m^3/h.m$.

Water should be contained in the gutter and drained back to the exterior. Any uncontrolled water in excess of 15 ml or more on the top surface of any exposed interior shall be considered as leakage.

B-4 In glass facade buildings, it is recommended to have provision for smoke/heat exhaust ventilation that automatically or by manual trigger expels smoke, heat and gases during a fire or emergency. These vents should be integrated into the building's smoke control system to improve evacuation safety, firefighting efforts, and overall air quality. These vents should be part of building facade and may also be located at suitable locations for effective exhaust. For further details in this regard, Part F 'Fire and Life Safety' of this NBCS may be referred.

In glass facade buildings, where airtight construction can restrict natural airflow, it is recommended to have make-up air vent also as a part of ventilation system that automatically or by manual trigger, introduces fresh air into the building to compensate for the air exhausted by smoke vents, HVAC systems, or other ventilation processes. These vents help maintain air balance and indoor air quality which ideally should be 85 percent to 90 percent of vented volume of smoke/heat.

ANNEX C

[*Clause* 5.3.2(b)]

TEST REQUIREMENTS FOR COATED GLASS

C-1 The coated glass that is used for the exterior of commercial and non-commercial (residential building) building should meet the test requirement listed in this Annex.

C-2 MEASUREMENT OF PERFORMANCE

The performance factors and spectral details of the coated glass shall be determined using standard accepted spectrophotometer equipment. The actual size shall be dependent on the type of equipment being used for the measurements. The transmittance of the measurement sample shall be measured with radiation of normal incidence at the following wavelengths:

a) 550 nm (representative wavelength for light and solar transmittance); and

b) 900 nm (representative wavelength for solar transmittance).

For glass claiming to have a low emissivity coating, a measurement of the reflectance shall be made at 8 µm using radiation of nearly normal incidence.

C-3 CONDENSATION RESISTANCE TEST

C-3.1 This test consists of subjecting the coated glass to a water saturated atmosphere at constant temperature. The samples have condensation continually forming on them and it is this condensation that may cause surface degradation.

C-3.2 Test apparatus should have a provision of four test pieces and the materials used for the inner walls shall be corrosion-resistant and shall not affect the test pieces.

C-3.3 Procedure

a) The water tank shall be filled with demineralized water, having conductivity lower than 30 µS and a *p*H higher than 5. The internal temperature of the cabinet shall be controlled by means of the reference thermocouple keeping a temperature of the reference glass piece of 40 ± 1.5 °C;

b) The test cabinet shall be in a room with an ambient temperature of 23 ± 3 °C. Care shall be taken to ensure that draughts, dust, moisture and solar radiation do not interfere with the test cabinet; and

c) The reference temperature shall be reached within 2 h of commencing heating. Condensation shall be seen to form on the glass pieces. The test is continued without interruption for the required time. Both the internal reference and the external air temperature shall be regularly checked.

C-3.4 Requirements

a) No defect, greater than 3 mm length;

b) Maximum one defect between 2 mm and 3 mm length;

c) Maximum five defects between 1 mm and 2 mm length;

d) No scratches, staining of the coating or clusters of pinholes greater than 1 mm;

e) When compared with the reference test piece, in both reflection and transmission, there shall be no significant colour change. This observation shall be made within 20 s; and

f) The transmittance measured at 550 nm and 900 nm shall differ by no more than ± 0.03 from the corresponding measured value on the reference test piece.

C-4 ACID RESISTANCE TEST

C-4.1 This test consists of subjecting the coated glass to a sulphur dioxide saturated atmosphere at constant temperature. The samples shall have condensation continually forming on them. It is this condensation together with the quantity of sulphur dioxide that may cause surface degradation. Test apparatus should have a provision of four test pieces and the material used for the inner walls shall be corrosion-resistant and shall not affect the test pieces.

C-4.2 Procedure

a) The test cabinet contains 2 litre of demineralized water having conductivity lower than 30 µS. When the cabinet is closed 0.2 litre of SO_2 shall be added and the heating system switched on;

b) The test consists of a repetition of 24 h cycles (*see* Fig. 21);

c) Each cycle consists of high temperature plus condensation period and an ambient temperature without condensation period; and

d) The temperature shall increase to 40 °C ± 1.5 °C in less than 1.5 h. During the next 6.5 h the test pieces shall be subjected to condensation in the SO_2 atmosphere.

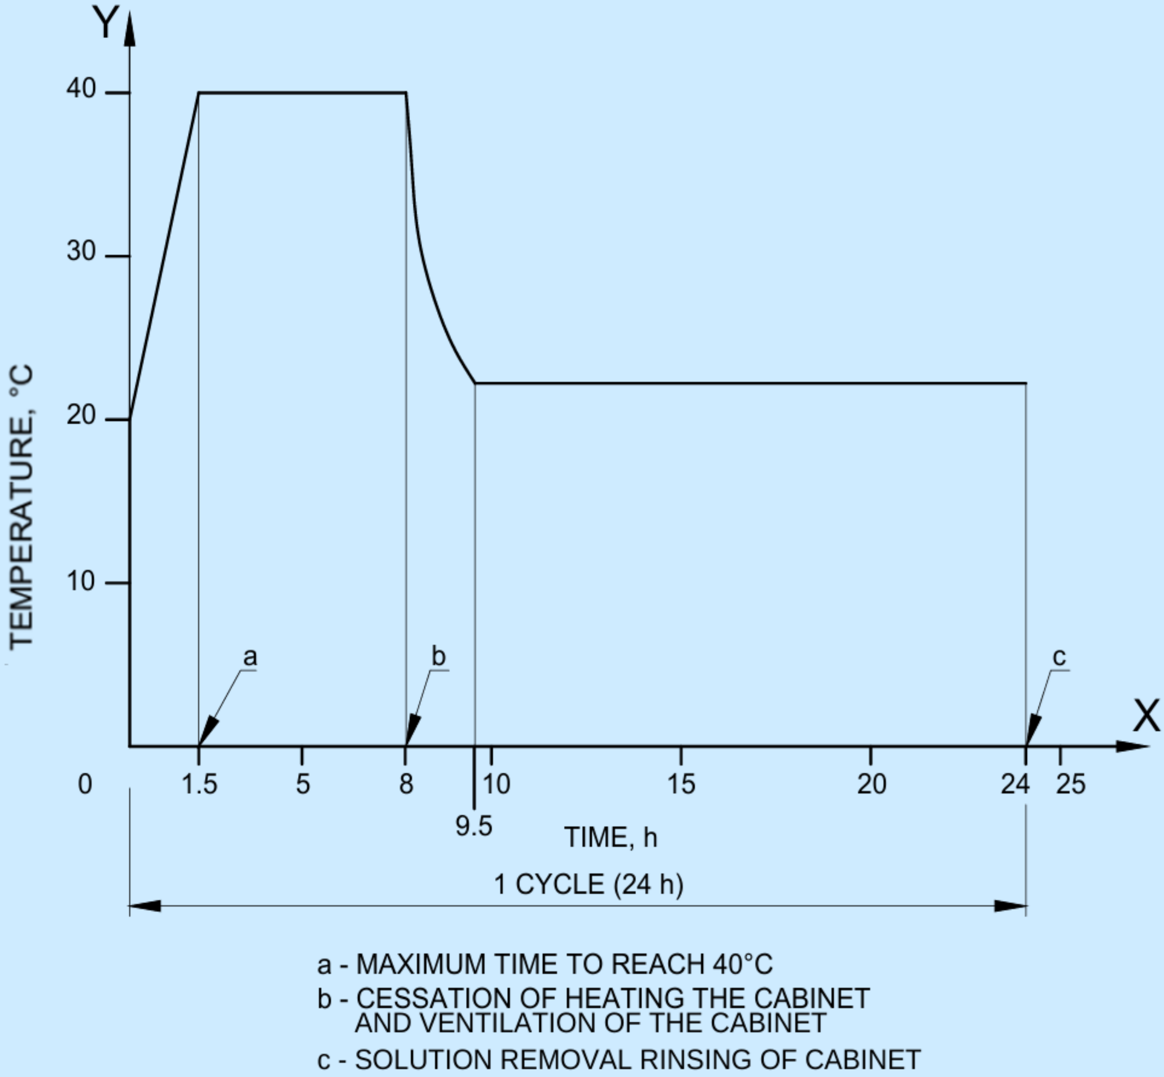

FIG. 21 24-HOUR CYCLE OF HEATING

C-4.3 Requirement

The transmittance measured at 550 nm and 900 nm shall differ by no more than ± 0.03 nm from the corresponding measured value on the reference test piece.

C-5 NEUTRAL SALT SPRAY

C-5.1 This test consists of subjecting the coated glass to neutral, water saline atmosphere at constant temperature. It is the water saline spray that may cause surface degradation.

Test apparatus should have a provision of four test pieces and the material used for the inner walls shall be corrosion-resistant and shall not affect the test pieces.

C-5.2 Procedure

a) The test cabinet shall be prepared and run for a minimum period of 24 h before the test pieces are placed within it. The neutral salt solution is made up by dissolving NaCl in demineralized water having conductivity lower than 30 µS, to produce a concentration of 50 ± 5 g/l at 25 ± 2 °C; and

b) The compressed air supplied to the spray nozzle shall be passed through a filter to remove all traces of oil or solid matter and shall be at an absolute pressure of 70 kPa to 170 kPa through a saturator at 40 ± 1.5 °C. The spray nozzle shall be made of inert material, with baffles to prevent direct impact of spray on the test pieces.

C-5.3 Requirements

a) No defect, greater than 3 mm length;

b) Maximum one defect between 2 mm and 3 mm length;

c) Maximum five defects between 1 mm and 2 mm length;

d) No scratches, staining of the coating or clusters of pinholes greater than 1 mm;

e) When compared with the reference test piece, in both reflection and transmission, there shall be no significant colour change. This observation shall be made within 20 s; and

f) The transmittance measured at 550 nm and 900 nm shall differ by no more than ± 0.03 nm from the corresponding measured value on the reference test piece.

C-6 ABRASION RESISTANCE TEST

C-6.1 This test consists of subjecting the coated surface of the glass to rubbing with a felt pad in dry condition. It is the type of pad, the loading on it and the number of strokes that may cause surface degradation.

C-6.2 Procedure

a) The metal finger shall be approximately 15 mm to 20 mm in diameter and shall be driven so as to produce a frequency of 60 strokes/min + 6 strokes/min, alternating forwards and backwards. The stroke length shall be 120 mm ± 5 mm. The strokes shall be parallel and ensure a constant pressure over the zone to be tested;

b) A circle shape with a diameter of 14.5 mm ± 0.5 mm;

c) The test sequence shall commence within 30 min of the sample being cleaned; and

d) The metal finger containing the felt pad shall be lowered on to the glass surface and a load of 4 N applied perpendicular to the glass surface via the felt pad.

C-6.3 Requirements

a) Ensure that the abraded area is uniform; and

b) The transmittance measured at 550 nm and 900 nm shall differ by no more than ± 0.03 nm from the corresponding measured value on the reference test piece.

C-7 DURATION OF TESTS

The duration of tests shall be as per the following:

Sl No.	*Test*	*Test Duration for Class*		
		A	B	S
(1)	(2)	(3)	(4)	(5)
i)	Condensation resistance	21 days	4 days	14 days
ii)	Acid resistance	5 cycles	1 cycle	5 cycle

NOTES

1 *Class A* – The coated surface of the glass can be positioned on the outer or the inner face of the building.

2 *Class B* – The coated glass can be used as monolithic glazing but the coated surface shall be on the inner face of the building.

3 *Class S* – The coated surface of the glass can be positioned on the outer or the inner face of the building but these types of coated glasses can only be used in specifically defined applications.

ANNEX D

[*Clauses* 6.1.9 *and* E-1.1.1(4)]

PROCEDURE FOR CALCULATING THE APPROXIMATE DEFLECTION AT CENTRE OF GLASS PANEL

D-1 Maximum glass deflection as a function of plate geometry and load may be calculated using the following:

$$\text{Deflection, } w = t \,.\, \exp\,(r_0 + r_1 X + r_2 X^2)$$

where

$X = \ln\{\ln[q(a.b)^2/Et^4]\}$

$r_0 = 0.553 - 3.83(a/b) + 1.11(a/b)^2 - 0.0969(a/b)^3$

$r_1 = -2.29 + 5.83(a/b) - 2.17\,(a/b)^2 + 0.206\,7(a/b)^3$

$r_2 = 1.485 - 1.908(a/b) + 0.815(a/b)^2 - 0.082\,2(a/b)^3$

where

E = Young's modulus of glass, N/mm^2;

q = net pressure on the pane, N/mm^2;

a = longer dimension, mm;

b = shorter dimension, mm; and

t = thickness of the glass pane calculated.

Example:

Lateral Deflection Calculation — Determine the maximum lateral deflection (w) of a vertical 1 200 mm × 1 500 mm × 6 mm rectangular glass plate subjected to a uniform lateral load of 1.80 kPa. The actual thickness of the glass is 5.60 mm as determined through direct measurement.

a = 1 500;

b = 1 200;

$r_0 = -2.689$;

$r_1 = 2.011$;

$r_2 = 0.213$;

$q = 1.80 \times 10^{-3}$ N/mm^2;

$E = 71.73 \times 10^3$ N/mm^2;

t = 5.60; and

x = 1.490.

Therefore, maximum deflection at the centre of glass is:

$$w = 5.6 \text{ x } \exp\,(-2.689 + 2.111 \times 1.490 + 0.213 \times 1.490^2)$$

$$w = 12.2 \text{ mm}$$

ANNEX E

(*Clause* 6.1.9)

MODEL CALCULATION OF GLASS THICKNESS

E-1 MODEL CALCULATION

E-1.1 Glass panel dimension width 1 200 mm and height 1 800 mm for location Chennai for annealed glass type.

E-1.1.1 *General Checks have to be done for Safety Performance*

a) The maximum area of glass panel is restricted to 15 m^2;
b) The maximum span of window is restricted to 4 m;
c) Applicable to normal, reflective, laminated, tempered and insulating glass; and
d) Applicable to rectangular panels properly fixed.

The procedure for calculating glass thickness is described below:

1) *Step* 1 — Calculate aspect ratio (AR_{max}) from Table 15.

Aspect ratio (AR_{max}) = Longer side/shorter side of glass
Aspect ratio = 1 800/1 200 = 1.5

2) *Step* 2 — Wind load calculation

For wind load calculation, reference shall me made to good practice [C-8(15)].

$$p_z = 0.6\ V_z^2$$

$$V_z = V_b.k_1.k_2.k_3.k_4$$

where

V_b = basic wind speed based on location {*see* Fig. 1 of good practice [C-8(15)]}.
k_1 = probability factor (risk co-efficient) {*see* **6.3.1** of good practice [C-8(15)]}.
k_2 = terrain roughness and height factor {*see* **6.3.2** of good practice [C-8(15)]}.
k_3 = topography factor {see **6.3.3** of good practice [C-8(15)]}.
K_4 = importance factor for the cyclonic region {*see* **6.3.4** of good practice [C-8(15)]}.
V_z = design wind speed at height z, in m/s.
p_z = wind pressure at height z, in N/m^2.

The design wind pressure (p_d) can be obtained as:

$$p_d = K_d.\ K_a.\ K_c.\ p_z$$

where

K_d = wind directionality factor {*see* **7.2.1** of good practice [C-8(15)]}.
K_a = area averaging factor {*see* **7.2.2** of good practice [C-8(15)]}.
K_c = Combination factor {*see* **7.3.3.13** of good practice [C-8(15)]}.

The value of p_d, however shall not be taken less than 0.70 p_z.

Design wind speed for Chennai location {Basic wind speed = 50 m/s taken from good practice [C-8(15)]} = 1 750 N/m^2.

3) *Step 3* — Strength factor

Based on the types of glass (laminated/tempered/insulating glass) pressure factor is calculated. To determine the thickness of laminated/ tempered/insulating glass, the design wind pressure P_{net} is modified as below:

$$P_{\text{net}} = p_d / P_f$$

where

P_f = pressure factor dependent on the type of glass.

The values of the pressure factor P_f can be taken from Table 14.

For annealed units, P_f = 1.0, therefore,

P_{net} = 1 750/1.0 = 1 750 N/m^2

At this stage the glass thickness value shall be calculated from the table and then the deflection and stress check be done as described below:

4) *Deflection Check*

The deflection of the glass can be calculated using the formula in Annex D. Actual deflection for the pane shall be obtained as below:

Deflection, $w = t.\ \exp(r_0 + r_1 X + r_2 X^2)$

$X = \ln\{\ln[q(a*b)^2/Et^4]\}$

$r_0 = 0.553 - 3.83(a/b) + 1.11(a/b)^2 - 0.0969(a/b)^3$

$r_1 = -2.29 + 5.83(a/b) - 2.17(a/b)^2 + 0.206\,7(a/b)^3$

$r_2 = 1.485 - 1.908(a/b) + 0.815(a/b)^2 - 0.082\,2(a/b)^3$

where

E = Young's modulus (71.7 x 10^3 N/mm^2);

Q = net pressure on the pane (N/mm^2);

A = longer dimension (mm);

B = shorter dimension (mm); and

T = thickness of the glass pane calculated.

The actual deflection is, 4 mm < 19 mm maximum allowable.

As per **6.3.6.2**, deflection at the centre of the glass for monolithic glass shall be the lesser of shortest span/60 or 19 mm.

Result: As 1200/60 = 20 mm, hence, 19 mm is the maximum allowable deflection.

Hence the glass thickness calculated is safe against deflection.

Glass Thickness Calculation:

$P_{\text{net}}.A = 200.0\ T^k$ (let $T \leq 6$ mm)

P_{net}= 1750

$A = 2.16\ \text{m}^2$

$K = 1.765$

$T = 5.28$ mm, therefore choose the thickness of glass as 6 mm.

ANNEX F

(*Table* 30)

PERFORMANCE TESTS FOR GLAZING SYSTEM

F-1 The following enlists the performance tests for glazing systems. The general test requirements shall be as per **7.1** of accepted standard [C-8(14)].

F-2 SEISMIC RACKING TEST

Criteria shall be the movement of the sub-structure in the horizontal (+/-) directions. Optional testing for vertical movements (+/-) shall be based on sub-structure movement to accommodate live load, long term creep, column shortening and thermal elongation or contraction. No glass breakage or fall out is allowed. No wall component fallout is allowed. The system shall comply with the requirements of air permeability and static water penetration tests as per the designed performance criteria. Post proof load testing, air permeability testing and static water penetration testing shall not be required unless specified otherwise.

F-3 BUILDING MAINTENANCE UNIT (BMU) PULL OUT TEST (WHEN APPLICABLE)

A tensile load of minimum 1.5 kN shall be applied on the BMU restraint in the following directions:

a) Outward and held for a period of 1 min;
b) Horizontally to the right and held for a period of 1 min;
c) Horizontally to the left and held for a period of 1 min;
d) Vertically upward and held for a period of 1 min; and
e) Vertically downward and held for a period of 1 min.

After each step the BMU restrain should not fail or have permanent deformation.

NOTE — If the load on the BMU restraints required by the BMU supplier is higher, the higher load shall apply.

ANNEX G

(*Clause* 9.4.3)

TESTING REQUIREMENTS FOR BLAST RESISTANT GLAZING SYSTEMS

G-1 OBJECTIVE

G-1.1 The purpose of this clause is to provide general guidelines about equipment, range conditions and procedures used to conduct the blast evaluation of glazing systems against the designed blast load and to verify that it meets the defined blast pressure load.

G-1.2 The glazing system is evaluated for its structural integrity by visual inspection only.

G-1.3 The safety precautions and regulations undertaken during blast resistant tests of glazing systems shall be as specified by the test agency.

G-1.4 Blast resistant test of glazing systems shall be carried out only by the accredited institutions/laboratories authorized by the Government of India.

G-2 TERMINOLOGY

G-2.1 Test Sponsor — Party requesting and sponsoring the test. The test sponsor may be its manufacturer or user (or his representative).

G-2.2 Test Agency — Party performing the testing and documenting the test results.

G-2.3 Test Specimen — The test specimen is provided as a complete assembly by test sponsor to the test agency. It may include glazing systems like glass door, glass windows/frames, glass panels, etc.

G-2.4 Trial Officer — Individual identified by the test agency responsible to complete the specified tests as required and to document the results in accordance with this test method. The Test Director shall sign all of the test reports.

G-2.5 Trial Safety Officer — Individual identified by the test agency nominated by the means of trial plan approved by the competent authority. The Trial Safety Officer is responsible for all the safety aspects during the trial time and safe conduct of trials.

G-3 APPARATUS

G-3.1 High Explosive

The high explosive charge (prepared by using TNT/equivalent charge) as mentioned by the test sponsor is used to generate the desired blast parameters for the performance evaluation of test specimen.

G-3.2 Instrumentation

The instrumentation system used for measurement of blast pressure comprises of piezoelectric based pressure sensors, signal conditioner, low noise anti-microphonic cables and data acquisition systems. The details are as follows:

G-3.2.1 *Pressure Sensor*

Pressure sensor is used to record pressure-time history of blast wave. The sensor contains piezoelectric crystal as a sensing element which produces an electric charge proportional to impinging pressure. The pressure sensor has an in-built circuitry that converts pressure to voltage signal. It requires installation control panel (ICP) constant current power supply which is provided by compatible signal conditioner.

G-3.2.2 *Low Noise Cables*

A special low noise anti-microphonic cable is used to transmit the signal from sensor to recording system. These cables are immune to tribo-electric effect and electromagnetic interference.

G-3.2.3 *Data Acquisition System* (*DAS*)

The DAS consists of an analog or digital recording system with a sufficient number of data channels to accommodate the pressure sensor(s) and any other electronic measuring devices. The DAS shall operate at a sufficiently high frequency to record reliably positive pressure and positive phase duration. The triggering of recording system is synchronized with explosion by using transistor-transistor logic system.

G-3.3 Photographic Equipment

Each test is documented with still photography. Video or high speed photography of the testing is deployed, if required.

G-4 PROCEDURE

G-4.1 The Trial Officer along with all team members will be responsible for the execution of the test. The Trial Safety Officer along with the range safety team will take care of the safety of personnel and property during the conduct of test.

G-4.2 The trial site location and range safety distance shall be decided by the test agency.

G-4.3 The parameters (identification number, shape, weight, dimensions, etc) are verified before trial. The documentary proof for the same shall be submitted by the test sponsor to the test agency.

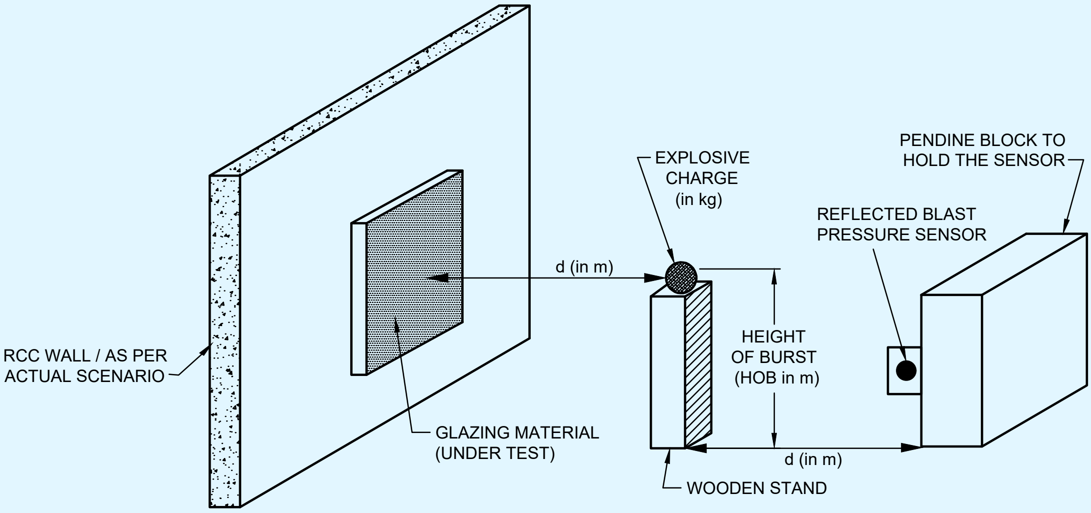
G-4.4 The test specimen is held on to the wall or as per actual scenario like wall having duct with or without room with the help of supporting frame such that no additional pressure gets generated on the glazing system when it is fixed to the frame using nuts and bolts.

G-4.5 The attack face of the test specimen will be towards the explosive charge (TNT/equivalent charge).

G-4.6 Photographic records of details of the glazing assembly and the test configuration are taken prior to the test. If a video photographic record of the response of glazing assembly during the test is desired, video cameras should be deployed.

G-4.7 The explosive charge (TNT/equivalent charge) is prepared as per the threat levels based on weight of explosive and standoff (*see* Table 34) or as defined by the test sponsor.

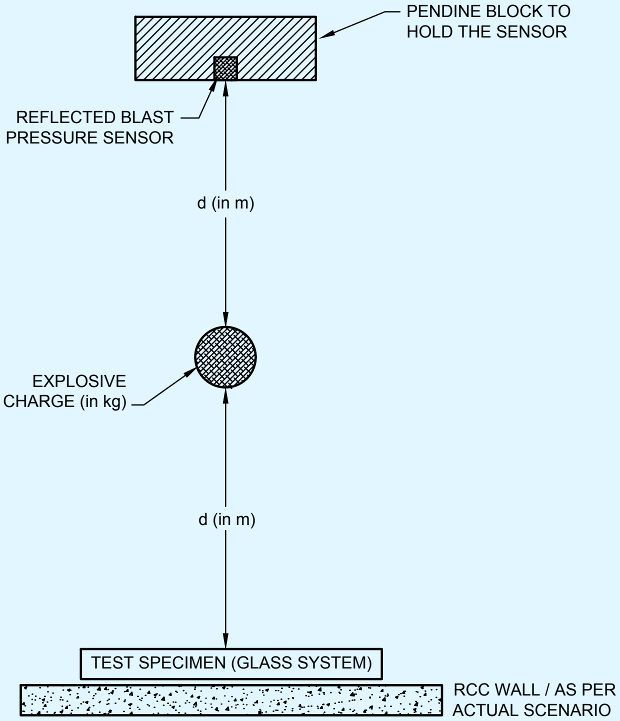
G-4.8 The explosive charge (TNT/equivalent charge) is positioned at a certain height of burst (HOB) and at distance *d* from the test specimen [as shown in Fig. 22 (isometric view) and Fig. 23 (top view)] (*see* Table 34).



EXPLOSIVE CHARGE (in kg)
PENDINE BLOCK TO HOLD THE SENSOR
REFLECTED BLAST PRESSURE SENSOR
d (in m)
HEIGHT OF BURST (HOB in m)
RCC WALL / AS PER ACTUAL SCENARIO
GLAZING MATERIAL (UNDER TEST)
d (in m)
WOODEN STAND

NOTE — The height of burst (HOB) shall be referenced from the hard stand on which the test specimen support (like RCC wall/test specimen support) stands.

FIG. 22 ISOMETRIC VIEW — SCHEMATIC OF TEST SETUP



PENDINE BLOCK TO HOLD THE SENSOR
REFLECTED BLAST PRESSURE SENSOR
d (in m)
EXPLOSIVE CHARGE (in kg)
d (in m)
TEST SPECIMEN (GLASS SYSTEM)
RCC WALL / AS PER ACTUAL SCENARIO

FIG. 23 TOP VIEW — SCHEMATIC OF TEST SETUP

G-4.9 The pressure sensor to measure the reflected blast pressure is deployed at distance *d* (as shown in Fig. 22 and Fig. 23). The pressure sensor is deployed in such a way that its sensing element is directed towards the explosive charge (TNT/equivalent charge).

G-4.10 The distance *d* and height of burst (HOB) varies depending on the threat level.

G-4.11 The pressure sensor is then connected to the data acquisition system through signal conditioner via low noise cables and tested to verify proper functioning.

G-4.12 The explosive charge (prepared by using TNT/equivalent) is then detonated by following all safety precautions ensured by trial safety officer and range safety team.

G-4.13 After the test, the visual inspection of the glazing assembly is done to evaluate its structural integrity. Adequate photography is taken after each test.

G-4.14 In case of misfire, the second attempt is done as per misfire drill of the test agency.

G-5 OUTCOMES

The structural integrity of glass system test specimen after the trial is evaluated by visual inspection according to the outcome categories specified in **9.4.3**.

G-6 REPORT GENERATION

G-6.1 Upon completion of the testing, the Test Director assigns a test number and record the test measurement and observations obtained from all test specimen(s) for preparation of test report.

G-6.2 The Trial Officer and the Test Director signs the test report and gets it approved from competent authority of the test agency.

ANNEX H

(*Foreword*)

INSTALLATION OF MIRRORS

H-1 This annex provides general guidelines, which is to be followed during the installation of mirror. Mirrors (Piece of glass silvered on one side, with a protective paint coating) are used in shops, gymnasiums, etc, where it is predominantly used as wall cladding. The mirror panels in such application use large panel size and it is recommended to follow the installation procedure in accordance with this Section.

H-1.1 The mirror should always be mounted on a perfectly flat, clean and dry surface free from acids and aggressive substances such as acid, solvent and cement mortar.

H-1.2 The mirror shall be mounted on wall or plywood and care is taken that the mirror is never stuck over unstable support (painted paper, paint or old plaster). It is recommended that the mirror installation is not done directly on the mirror supports. In order to have good ventilation, the following spacing behind the mirror is recommended depending on the height of the mirror panel:

a) A space of 5 mm for a mirror less than 1 m height; and

b) A space of 10 mm for a mirror greater than 1 m height.

Figure 24 gives typical details of the installation of mirrors. During the installation of mirror panels at several levels that is, one above the other, it is recommended to provide a space of 10 mm at the top and at the bottom for circulation of air. The side of the mirror is designed with a minimum 1 mm or 2 mm of interleaving space. When mirror is fixed in a profile (frame), care is to be taken to maintain perfectly dry and clean frame. It is recommended that mirror is supported on hard non-metallic/plastic wedges of at least 3 mm, to raise the mirror and thus avoid contact with the condensed water which could accumulate in the profile. If the mirror is screwed on, the screws of a suitable dimension is designed, with the interleaving and washers (*see* Fig. 25) made of plastic to avoid any direct glass-metal contact. To minimize the risk of breakage, cracks and splinters during screw-mounting the mirror, it is recommended to use synthetic protective collars.

H-1.3 For the adhesive used to mount mirrors, care should be taken to ensure that the adhesive is compatible with the protective coatings on the mirror. It is recommended to use only neutral binding agents such as alkoxy silicone, oxime silicone, etc. Avoid use of acid silicones, such as acetoxy silicones which contain acetic acid or water/rubber/polyurethane-based glues.

H-1.4 In the high humidity areas (for example bathrooms), it is recommended to seal the edges with neutral silicone to protect the backing paint from damage due to moisture and enhanced protection from moisture. It is recommended to use double sided adhesive tapes to fix the mirror on the mounting surface (*see* Fig. 26). The adhesive tapes used for installation shall be certified to be compatible with the mirror and the adhesive or the adhesive tapes shall always be fixed vertically.

ANNEX J

(*Foreword*)

GLASS RAILINGS

J-1 GENERAL

Glass railings are generally sought in institutional, commercial, residential buildings and special structures like stadiums, foot over bridges, etc. Glass of appropriate thickness when used as a railing can provide transparency and when engineered properly can provide structural performance too. In public places such as stadiums, foot over bridges, shopping malls, etc, use of frameless glass railing shall be avoided and framed systems with vertical balustrades and glass infill panel may be used with proper design as per the design provisions.

The basic requirement of a parapet, which a glass railing (if so used) intends to substitute, shall be met with. This includes protecting people from falling and in some cases to control movement. Careful consideration, including in design, shall be made/determined where glass railings are used.

> NOTE — Notwithstanding the above, the potential benefits including safety (through psychological aspects) of regular railings shall be borne in mind.

J-2 PRELIMINARY CONSIDERATIONS

In the assessment of the need for a railing and the type of railing to be provided, the designer should give consideration to the likely hazards, the building use and the risks to building users. Where, in a building, more than one use of the building is anticipated, either the railing design should be chosen to suit the worst case, or more than one type of railing should be provided, as appropriate, to the location. Generally, when there is a change in adjacent levels (600 mm in dwellings, 380 mm in other buildings) a railing is needed to restrict movement of people.

The railing adopted should be designed so as to minimize the risk of persons falling, rolling, sliding or slipping through gaps in the railing. In dwellings and other buildings which can be accessed by children, gaps in railing or infill should not be large enough to permit a sphere of 100 mm diameter to pass through, making due allowance for deflection under load.

The designer should ensure all the elements of the railing system satisfy the criteria given in available relevant standards.

For general safety, the finished barrier should have no sharp edges or projections that could cause injury to persons or clothing. Infill panels and balusters are intended to provide support and protection to users, and should be designed to restrain people without causing additional injury from sharp edges, thin sections, open-ended tubes, projecting details, etc.

The design shall be based on the horizontal uniformly distributed load (UDL) applied at a notional height of 1.1 m above finished floor level, even though the minimum permissible height of the railing may be less (the notional design height of 1.1 m is chosen as being representative of the height of the centre of gravity of a human being above the datum level).

J-3 GLASS RAILING TYPES

There are four common types of railings that are used to fix glass.

a) *Full Height Railing* — Where glass forms part or whole of a wall element, the railing should be carefully designed as per the relevant standards and as per this Section, if any part of the glass comes below the minimum railing height (*see* Table 35 and Fig. 27).

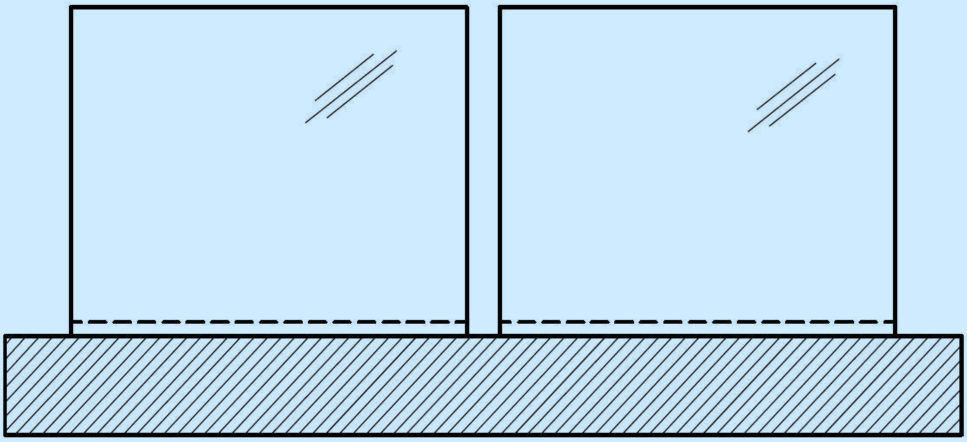

FIG. 27 FULL HEIGHT RAILING

b) *Railings with a Glass Infill Panel* — In this type of railing, the main frame of the railing (that is, top rail and baluster) should be designed to withstand the loads applied to the top rail and the glass should be used to form infill panels. It should be noted that the glass provides no support to the main frame. The designer shall ensure that, irrespective of the fixing type, in the event of glass breakage, the broken glass remains securely attached to its framing or supporting structure, thereby preventing safety hazards. This can be further sub-categorized into 4 types:

1) *Glass supported on vertical edges only* — This may involve the vertical edges of the glass being supported in a rebate into the side of each vertical post. The top and bottom edges of the glass are exposed. The glass may also be supported by patch fittings fixed to the posts. In all cases a handrail is required (*see* Fig. 28).

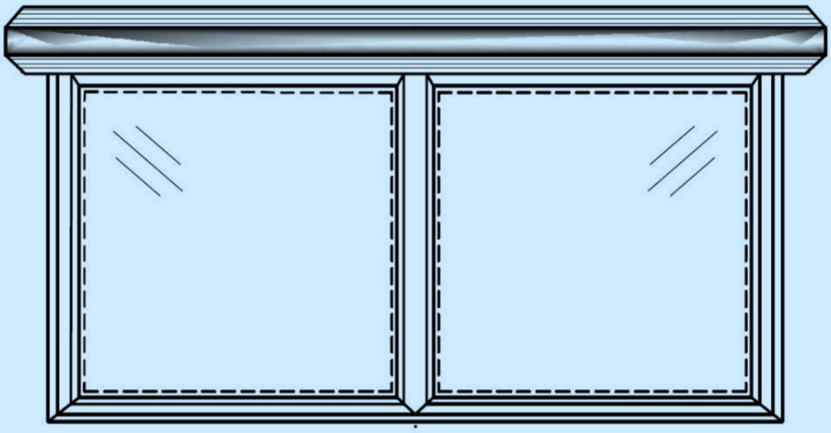

FIG. 28 GLASS SUPPORTED ON VERTICAL EDGES ONLY

2) *Glass supported on horizontal edges only* — This may involve a handrail at the top, and a channel or a rail at the base of the glass. In this case the handrail should be designed to carry the railing load with the glass designed to carry the infill load (*see* Fig. 29).

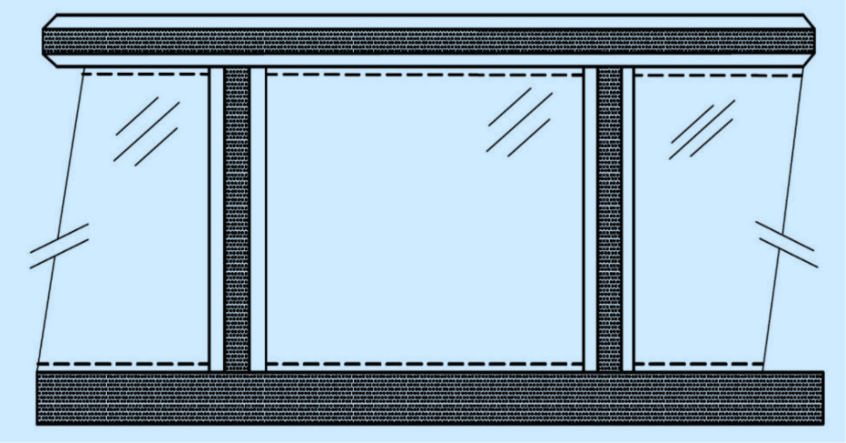

FIG. 29 GLASS SUPPORTED ON HORIZONTAL EDGES ONLY

3) *Glass supported on all four edges* — (*See* Fig. 30)

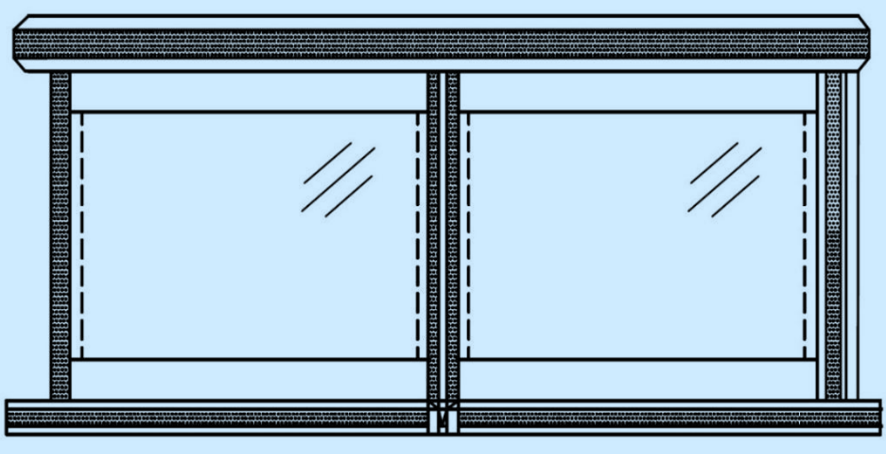

FIG. 30 GLASS SUPPORTED ON ALL FOUR EDGES

4) *Glass fixed by patch/bolted fittings* — This system requires the use of two rows of bolts (commonly) to provide a stiff fixing which minimizes panel deflection. There are a variety of bolt fixing types available in the market, so design and performance information should be sought for each type. The purpose of these fixings is to transfer the force applied to the railing into the support structure. These fixings occupy a small surface area on the glass which can produce high stresses in the glass, so careful analysis is required to determine suitable glass thickness, fixing spacing and size. Glass fixings shall be designed to avoid high local stresses and minimize the risk of failure. Minimum fixing sizes shall be used, and for large panels exceeding 2 m in dimension or under high wind pressure exceeding 2.5 kPa, fixings shall accommodate rotations by using articulated fixings (*see* Fig. 31).

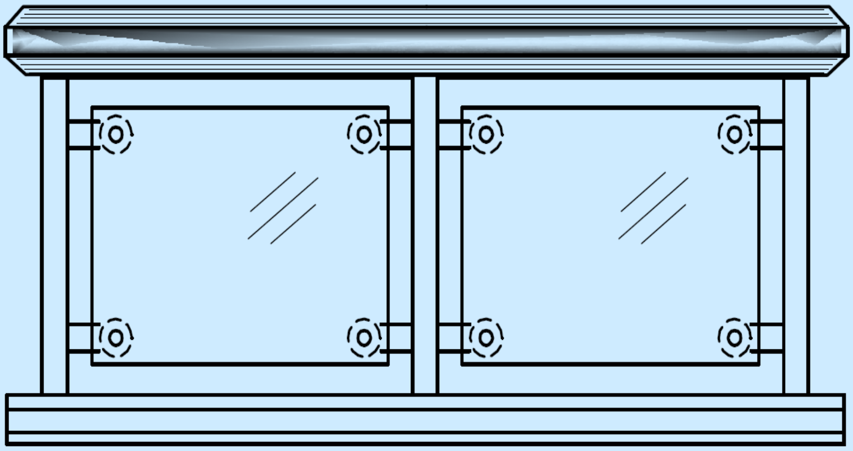

FIG. 31 GLASS FIXED BY PATCH/BOLTED FITTINGS

c) *Free Standing Glass Protective Railing* — In this type of railing, the glass should be designed to withstand the design loads. Each glass plate should be rigidly clamped to the structure along its bottom edge, the handrail attached to the top edge of the glass and there should be no balusters. In the event that a free standing railing is supplied without a handrail, each panel should be able to withstand the entire appropriate design load. This applies to vertical glazing and glass within 15º of vertical. Adequate provision for drainage of water should be made in the base structure to avoid any water ponding which may cause delamination issue. Laminated safety glass shall be used for this application. Clamping and brackets shall be designed with adequate anchorage, and the main supporting building elements (beam/slab) shall be verified to meet the required minimum thickness. The bottom glass clamping embedment shall be a minimum of 100 mm, regardless of railing size. The bottom clamping member shall provide continuous support along the glass bottom edge. In the event of glass breakage, the glass panel shall remain securely in place without risk of detachment or falling (*see* Fig. 32).

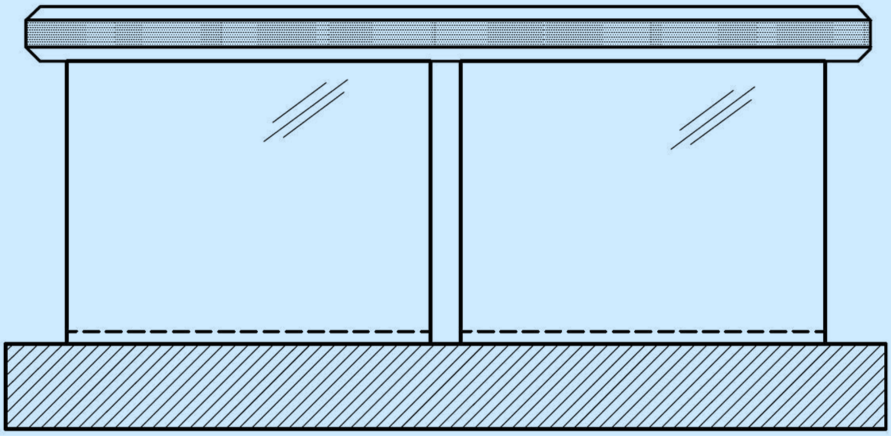

FIG. 32 FREE STANDING GLASS PROTECTIVE RAILING

d) *Bracket Systems* — These systems are an extension of the bolt fixed system where the bolts are part of a bracket and the bracket is fixed to the floor or the face of a concrete slab, steel or timber structure. The use of these systems shall be investigated carefully as they can develop very high stresses in the glass where the brackets are located. The design shall balance glass thickness and bracket location to produce an adequate system. Some systems may be designed to produce test data, to justify their use. This data shall be studied carefully as there have been some cases where such data has been shown to be inadequate. Proper interpretation of these test data shall also become necessary (*see* Fig. 33).

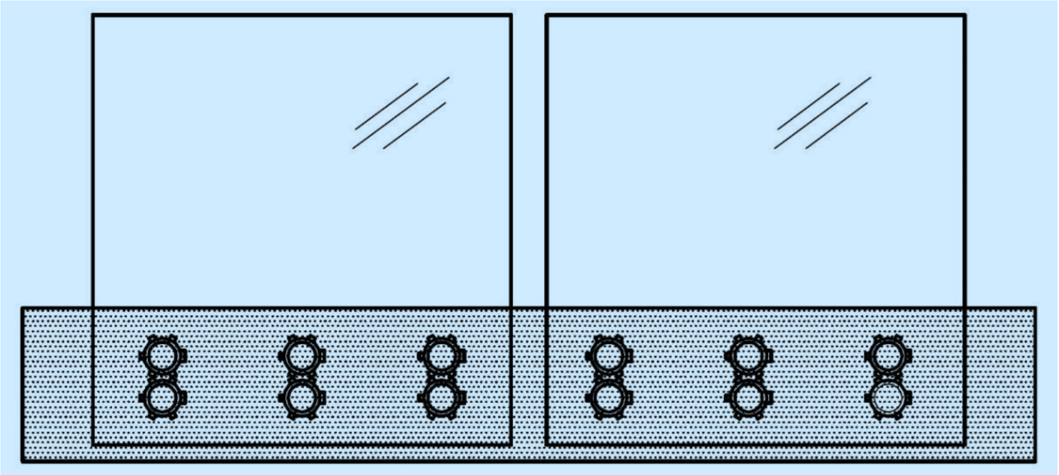

FIG. 33 BRACKET SYSTEMS

e) *Bracket Systems* — Bottom supported with surface attached/bolted Handrail — Glazing as structural member (*see* Fig. 34).

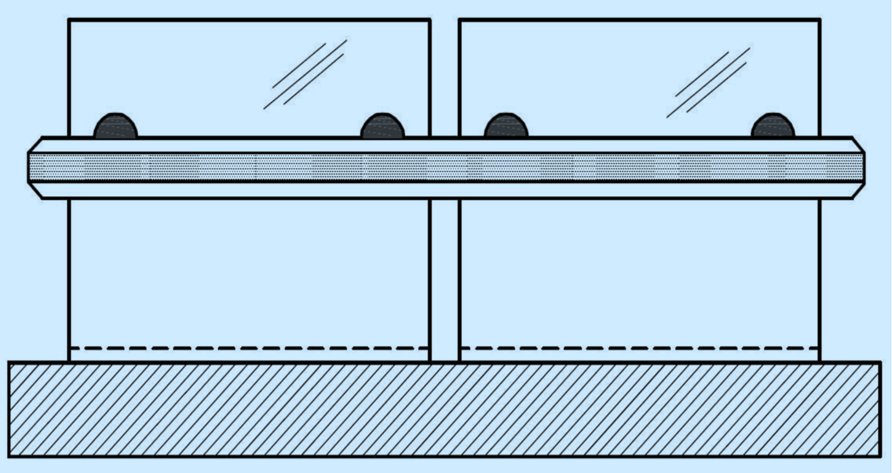

FIG. 34 BOTTOM SUPPORTED WITH SURFACE ATTACHED/BOLTED HANDRAIL — GLAZING AS STRUCTURAL MEMBER

Table 35 Minimum Barrier Heights

[*Clauses* J-3 (a), J-4.1, J-5.4.1 *and* J-6.1]

Sl No.	Use	Position	Height mm
(1)	(2)	(3)	(4)
i)	Single-family dwelling	a) Barriers in front of a window up to 10 floors	800
		b) Barriers in front of a window from 11th floor to 20th floor	1 100
		c) Barriers in front of a window above 21st floor	1 200
		d) Stairs, landings, ramps, edges of internal floors	900
		e) External balconies including *balconet*, edges of roofs:	
		1) up to 20th floor	1 100
		2) 21st floor and above	1 200
ii)	All other uses	a) Barrier in front of a window	800
		b) Stairs	900
		c) Balconies and stands, etc having fixed seating within 530 mm of the barrier	800
		d) Balconies and stands, etc having fixed seating within 530 mm of the barrier, provided the sum of the barrier width and the barrier height is greater than 975 mm	750
		e) Other positions including balconets	1 100

NOTE — Height shall be measured from the top edge of the railing to the highest point of the floor where occupants can stand. This measurement shall be from the top of any ledges, up-stands, or toe walls, if present at the base.

J-4 DESIGN CONSIDERATIONS

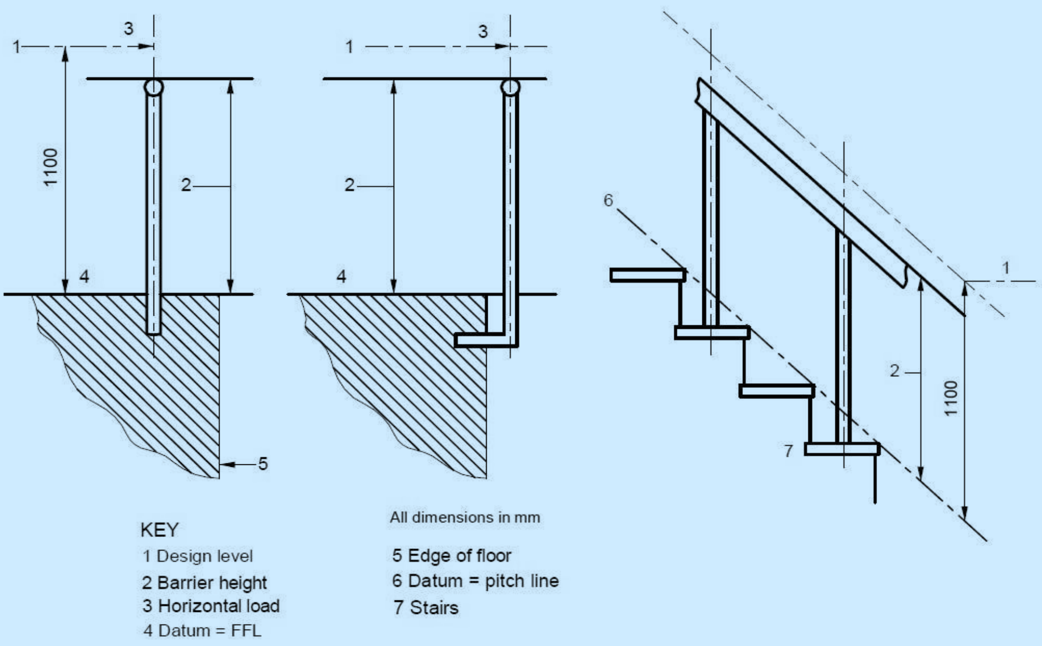
The designer shall first determine the purpose of the railing. Once this is done, the appropriate load requirement can be derived. Typical values (minimum requirements) of railing loads to be chosen are given in Table 36 (If so desired by the designer, higher values than that in the Table 36 may also be chosen).

J-4.1 General

Railings should be designed to resist the most unfavourable likely imposed loads and wind loads separately without unacceptable deflections or distortions. Heights of railings shall be same as that for parapet walls as per other Parts of this NBCS. The railing height above datum is defined in Fig. 35. The minimum heights for each railing location shall be as given in Table 35.

The height of glass railings installed on top of low parapet walls should be measured from the top of the parapet and not at walk level.

For railings, either permissible stress or limit state design procedure should be used, according to the recommended procedures. When using limit state design, the partial safety factors for loads and materials should be those recommended by the appropriate standard for relevant materials. The deflection of the railing shall be determined as per serviceability limit state.



NOTE — In design, the horizontal uniformly distributed line load acts at a height of 1.1 m above datum level, irrespective of the actual height of the element.

FIG. 35 DATUM, BARRIER HEIGHT AND DESIGN HEIGHT

J-4.2 Loading

Minimum horizontal imposed loads appropriate to the design of parapets, railings, balustrades and other elements of structure intended to retain, stop or guide people, should be determined in accordance with Table 36, which recommends a uniformly distributed line load for the railing and a uniformly distributed and point load applied to the infill.

NOTE — These are not additive and should be considered as three separate load cases, all loads being determined according to the type of occupancy which reflects the possible in-service conditions.

Horizontal uniformly distributed line load should be applied at design height as presented in Table 36 or at design level (1 100 mm) for railings higher than the design height.

Uniformly distributed load should be applied to the area below the design height.

Point load should be applied at the most onerous point anywhere on the railing structure.

NOTE — For clarity, the design level (the level at which the horizontal uniformly distributed line load ought to be considered to act) is shown in Fig. 36.

Sl No.	*Building*	*Element*	*Strength*	*Height* (H)	
(1)	(2)	(3)	(4)	(5)	
i)	Single family dwelling	Stairs landings, ramps edges of internal floors	0.36 kN/m	900 mm for all elements			External balconies and edges of roofs	0.74 kN/m	1 100 mm	

Sl No.	*Building*	*Element*	*Strength*	*Height* (H)	
(1)	(2)	(3)	(4)	(5)	(6)
ii)	Factories and warehouses (light traffic)	Stairs, ramps	0.36 kN/m	900 mm			Landing and edges of floor	0.36 kN/m	1 100 mm	
iii)	Residential institutional, educational, office and public building	All location	0.74 kN/m	900 mm for flights otherwise 1 100 mm	iv)	Assembly	Within 530 mm in front of fixed seating	1.5 kN/m	800 mm (H1)			All other locations	3.0 kN/m	900 mm for flights elsewhere 1 100 mm (H2)	
v)	Retail	All locations	1.5 kN/m	900 mm for flights otherwise 1 100 mm	vi)	All buildings	At opening windows		800 mm			At glazing to changes of level	To provide containment	Below 800 mm	
NOTE — *H* is the height at which the applied load (horizontal design load) is located and it need not be the height of the barrier itself.

FIG. 36 HEIGHT LIMIT FOR THE UNIFORM LOADING FOR VARIOUS CATEGORY OF BUILDINGS

Table 36 Minimum Horizontal Imposed Loads for Parapets, Barriers and Balustrades

[*Clauses* J-4, J-4.2, J-4.4 *and* J-4.6]

Sl No.	Type of Occupancy for Part of the Building or Structure	Examples of Specific Use	Horizontal Uniformly Distributed Line load	Uniformly Distributed Load Applied to the Infill	A Point Load Applied to Part of the Infill
			kN/m	kN/m^2	kN
(1)	(2)	(3)	(4)	(5)	(6)
i)	Domestic and residential activities	a) All areas within or serving exclusively one single family dwelling including stairs, landings, etc but excluding external balconies and edges of roofs	0.36	0.5	0.25
		b) Other residential, that is houses of multiple occupancy and balconies, including Juliette balconies and edges of roofs in single family dwellings	0.74	1.0	0.5
ii)	Offices and work areas not included elsewhere, including storage areas	a) Light access stairs and gangways not more than 600 mm wide	0.22	—	—
		b) Light pedestrian traffic routes in industrial and storage buildings except designated escape routes	0.36	0.5	0.25
		c) Area not susceptible to overcrowding in office and institutional buildings, also industrial and storage buildings except as given above	0.74	1.0	0.5
iii)	Areas where people might congregate	Areas having fixed seating within 530 mm of the barrier, balustrade or parapet	1.5	1.5	1.5

Table 36 (*Concluded*)

		b) External balconies including Juliette balconies and edges of roofs. Footways and pavements within building curtilage adjacent to basement/sunken areas	0.74	1.0	0.5
vi)	Areas susceptible to overcrowding	a) Footways or pavements less than 3 m wide adjacent to sunken areas	1.5	1.5	1.5
		b) Theatres, cinemas, discotheques, bars, auditoria, shopping malls, assembly areas, studio. Footways or pavements greater than 3 m wide adjacent to sunken areas.	3.0	1.5	1.5
vii)	Retail areas	All retail areas including public areas of banks/building societies or betting shops	1.5	1.5	1.5
viii)	Vehicular	Pedestrian areas in car parks, including stairs, landings, ramps, edges or internal floors, footways, edges of roofs	1.5	1.5	1.5

In general, the following load combinations as described in **J-4.2.1** to **J-4.2.3** should be applied.

J-4.2.1 *Free Standing Glass Protective Railing* (*Without any Balusters*)

It requires four design loadings to be taken into account:

a) Infill load, in kN;
b) Uniform load, in kN/m;
c) Concentrated load, in kN; and
d) Shot bag test load, in Joules.

J-4.2.2 *Railing with Glass Infill Panel*

It requires four design loadings to be taken into account:

a) Infill load, in kN;
b) Uniform load, in kN/m;
c) Concentrated load, in kN; and
d) Shot bag test load, in Joules.

J-4.2.3 *Full Height railing*

It requires four design loadings to be taken into account:

a) Infill load, in kN;
b) Uniform load, in kN/m;
c) Concentrated load, in kN; and
d) Shot bag test load, in Joules.

J-4.3 Wind Loads

External railings should be designed to resist the wind loads given in good practice [C-8(15)].

J-4.4 Deflection

Railings for the protection of people should be of adequate strength and stiffness to sustain the applied loads given in Table 36. In addition, a railing that is structurally safe should not possess flexibility to such an extent so as to create a false alarm to building users when subject to normal service conditions. Therefore, for serviceability considerations, the limiting condition for deflection appropriate for a railing for the protection of people is that the total horizontal displacement of the railing at any point from its original unloaded position should not exceed the deflection limits determined from the relevant structural design code (where applicable) for the material used, or 25 mm, whichever is the smaller. Where the infill of a railing is subjected to the imposed loads given in Table 36, or if appropriate, other calculated design loads, the displacement of any point of the railing should not exceed H/65 or 25 mm, whichever is lower. These deflection limits shall apply to the deflection of the cantilevered top edge of the railing, measured perpendicular to the glass plane or the direction of the wind load.

J-4.5 Fixings, Attachments and Anchorage

The strength of fixings, attachments and anchorage securing the railing to a substrate should be adequate to sustain a loading greater than that to which the railing will be subjected. All joints should be designed to provide the full strength of the members being joined. To that end, where any uncertainty exists with regard to the strength of any component in the fixing, the design loading factors should be increased by 50 percent.

While designing fixings, particular care should be taken to account for the material into which the fixing is placed, the spacing between fixings, the edge distance, and where the substrate is concrete, the position of reinforcement. Building elements (beam/slab/up-stand) shall have adequate thickness and shall be composed of structural reinforced cement concrete (RCC) or steel. The designer shall exercise caution when the thickness of the concrete element is less than 100 mm, as adequate embedment may not be achievable. The designer shall ensure that the concrete element is cast with high quality and shall refrain from fixing to any loose concrete. Design of anchors shall conform to the requirements of accepted standard [C-8(30)].

NOTES

1 The recommendation of an additional load factor of 1.5 is intended to ensure that under an extreme load condition, railings give an indication of failure by deflection or distortion and not by total collapse, as may be brought about by a failure of the fixing, attachment or anchorage system. Where the design strength of a proposed system of fixing to an existing substrate cannot be determined with reasonable accuracy by theoretical consideration, load testing should be used to validate the design.

2 A factor greater than 1.5 on railing load design might also be chosen based on the importance desired by the designer/parties concerned.

J-4.6 Testing

It is recommended to conduct the tests as detailed in this clause, on railings provided for the type of occupancy classified as 'Areas susceptible to overcrowding', as specified in Table 36. For all other occupancy types, the tests to be conducted on railings for performance evaluation, shall be mutually decided between the parties concerned.

J-4.6.1 *Test Selection*

Load test methods for the uniform load test and the concentrated load test are selected based on the performance specification.

J-4.6.2 *Sequence of Test Method*

Specimens tested for two or more of the loading conditions are subjected first to the in-fill load test, followed by the uniform load test, and then the concentrated load test and shot bag glazing impact test, steel nose pendulum impact, and sphere penetration evaluation, in that order, unless directed otherwise by the performance specification.

J-4.6.2.1 *Apparatus and load application*

a) *Assembly support fixture* — An assembly support fixture shall ensure the rigidity normally provided to an assembly in a building by the ceiling, floor, and walls. The support fixture for the specimen shall consist of a vertical wall section constructed from nominal steel or 2 by 4 wood studs, 400 mm on centre, with a rough opening of sufficient size to support the test specimen in accordance with the manufacturer's specifications. The limiting deflection of the wall shall be L/175 (based on the anticipated loads);

b) *Load attachments* — Brackets, fasteners, or other devices used in performing these tests shall be designed and attached so as to minimize their influence on the test results;

c) *Shot bag, traction and release system* — The shot bag shall be of weight 45.4 kg as described in **6.4.2.5** and **6.4.6** of accepted standard [C-8(3)]. The suspension device shall conform to **6.4.2.6** of accepted standard [C-8(3)] and the Traction Release system shall conform to **6.4.2.7** of accepted standard [C-8(3)];

d) *Load measuring device* — Load and time-measuring devices with an accuracy of ± 2 percent of the full scale shall be incorporated in the test setups. The scale ranges used shall assure that the performance levels are within an accuracy of ± 5 percent; and

e) *Rate of loading* — The rate of loading shall be such that the maximum specified load is achieved in no less than 10 s and no more than 5 min**.** Maintain the maximum specified load for 1 min before releasing. [Warnings: 1) Possible injury to personnel and damage to the test equipment and instrumentation prior to, during, and after load application by any unexpected release of potential strain energy accumulated during testing can occur and shall be given consideration. 2) If tests are conducted in a structure and not in a testing laboratory, exercise caution against unwanted damage to the building, its components, and its finish].

   For in-fill testing, use a bearing plate with appropriate cushioning between the plate and the glazing. The bearing plate should be 0.09 m^2.

Each load test to be performed on a new specimen or the undamaged specimen from the previously applied test. Perform only one test per glazing in-fill type on each of the three specimens at the most critical point of the system.

J-4.6.3 *Sampling*

A minimum of three representative replicate specimens of each type of system shall be tested. Sequential testing of the same specimen shall be permissible provided no breakage of any component occurs during the previously performed tests.

J-4.6.4 *Test Specimens*

The specimen installation, including the post spacing, shall be the same as the actual field installation. The specimen shall have a minimum of three posts or minimum two largest glass panels. Each unique attachment scenario shall be tested.

Multiple types of infill panels shall be qualified within one test, provided each panel is individually glazed into the system prior to the start of the test. No substitution of infill product shall be permitted once testing has commenced.

J-4.6.5 *Installation*

The glass rail, guard, or balustrade system being tested shall be installed in accordance with the manufacturer's or designer's specifications.

J-4.6.6 *Test Procedure*

J-4.6.6.1 *In-fill load test*

The test specimen shall be capable of satisfactorily resisting the required test load applied over a 0.09 m^2 area normal to the in-fill. The test load shall be applied at the intersection of the horizontal and vertical centre lines of the in-fill, unless specified otherwise by the performance specification or the purposes of the test. If it is determined that another location will yield lesser results, that position should be used instead of the indicated intersection point of the centre lines. Record deflection of the in-fill at the point of maximum deflection of the in-fill.

J-4.6.6.2 *Uniform load test*

Subject the top rail or other rail of the test specimen to the required maximum uniform test load applied vertically and horizontally, as required by the performance specification. Required vertical and horizontal test loads shall be applied separately and sequentially, unless otherwise required by the performance specification or to meet the purpose of the test. Record the deflection at mid-span during each test.

J-4.6.6.3 *Concentrated load test*

The top rail or other subject rail of the test specimen shall be subjected to the concentrated test load applied vertically and horizontally, as required by the performance specification. Apply required vertical and horizontal test separately and sequentially, unless otherwise required by the performance specification or to meet the purpose of the test. The required concentrated test load shall be applied at the following three critical locations – rail mid-span between posts, top rail adjacent to a post (maximum 75 mm from post) and top of a single post. Test loads are to be applied and deflection recorded sequentially, one location at a time. The load applied on the rail adjacent to the post can be applied to the opposite post from which the top-of-post-test was performed. In the case of swing gates, if the structure of the gate requires locating the test load more than 75 mm from a post due to hinge or latch construction, the load should be located as close to the 75 mm maximum distance from the post as is possible. Record the deflection at the point of application of the load.

J-4.6.6.4 *Shot bag impact test*

Any protective masking or decorative components shall be removed from the glazing material.

To position the impactor at the selected drop height, a traction force shall be applied to raise the impactor such that the axis of the impactor shall be aligned with the suspension cable, with the cable remaining taut. To ensure this, the top and bottom ends of the impactor shall be connected to the release device by a suitable link.

To reduce bag deformation during testing, the bag shall be rotated about the axis of its suspension device before each specimen or sample set, by no less than 30º, and by no more than 90º.

To reduce bag damage during testing, a thin homogeneous or non-woven plastic film no more than 0.13 mm thick or a loosely draped woven cloth towel weighing no more than 0.05 g/cm^2 shall be permitted to be suspended vertically from its top edge directly in front of the surface of the specimen at a distance no more than 10 mm.

The impactor shall be suspended from an overhead support, located so when at rest it will, at its maximum diameter, be located no more than 12 mm from the surface of the specimen and no more than 50 mm from the impact location of the glazing infill specimen.

Raise the impactor to the required height (460 mm, 1 220 mm or 1 525 mm) and stabilize it. The suspension device shall be taut and the axes of the impactor and cable shall be aligned.

The impactor, stabilized in the launch position in a vertical plane normal to the test specimen, shall be released and falls without initial velocity or axial rotation.

If the glazing does not break, the impactor is to be raised to the next designated height and glazing impacted from the new height. Glazing found to be unbroken and remaining completely in the frame after impact shall be recorded as intact.

J-5 GLASS

The use of glass in railings, the type and thickness of glass required for various support conditions shall be as given below. If designed properly, glass can form a structural component of the railing, or the railing may be designed to have a structural component made from another material such as steel or aluminium, with glass acting as an infill panel only. This places a lesser load on the glass as the major load is taken by the structural component.

NOTE — There are certain situations, particularly under some lighting conditions, where the presence of transparent glass is not readily evident and suitable manifestation should be provided.

J-5.1 Types of Glass

It is recommended to use laminated safety glass for all types of glass railing applications, whether framed or frameless. In the event of glass breakage, the glass panel shall remain in place without falling from its position.

J-5.2 Working of Glass

When toughened glass or heat-strengthened glass is used in laminated glass, it shall conform to accepted standard [C-8(7)] for toughened glass and accepted standard [C-8(8)] for heat-strengthened glass.

J-5.3 Fixing of Glass

Contact between glass and any other hard material (including other glass parts) should be prevented. Rubber gaskets or other glazing materials should be used with frame sections. The frame section should give a minimum of 15 mm edge cover to the glass unless it can be shown by test or calculation that the frame will retain the glass under load while conforming to design requirements.

The frame and/or fastenings should be designed so that they do not tend to distort the glass panel. This is particularly important with bolted connections, which can exert considerable forces on the glass, where particular attention should be paid to the alignment and position of the fasteners in order to avoid unnecessary stresses being developed.

J-5.3.1 *Bolt Fixing of Infill Panels*

At the bolted connections there should be clamping plates and gaskets on both sides of the glass that provide a minimum of 50 mm diameter cover to the glass. These plates should be not less than 6 mm thick in steel or 10 mm thick in other suitable metals.

Where the length of a glass pane is greater than the span between the bolted connectors, giving rise to a cantilevered portion of the pane, the cantilevered portion should be less than one-quarter of the span between the bolted connectors.

Under the design loads, the railing should be designed so that the relative in-plane movement of the bolted connections in the same panel is not greater than 2 mm.

The glass, framing system and connections of railings and infill panels should be capable of sustaining and safely transmitting the design loads to the supporting structure.

J-5.4 Design of Glass

J-5.4.1 *Design of Glass in Full Height Protective Railings*

Glass partly or totally below the minimum railing height should be designed to satisfy the appropriate design criteria. Any part of a glass pane below the minimum railing height should sustain the infill loads. Where there is glass at the minimum railing height given in Table 35, the glass should also sustain the line load applied at the design level.

For any specific information on the glass size relative to the glass type, support system, loadings and thickness, available standards or the manufacturer recommendations should be sought.

J-5.4.2 *Design of Glass Infill Panels*

Infill panels should be designed to satisfy the appropriate design criteria as below:

a) *Fully framed infill panels* — The deflection of the glass in fully framed infill panels should be as per recommended deflections;

b) *Two-edge framed infill panels* — The deflection of the glass in two-edge framed infill panels should be as recommended under **J-4.4** taking *L* as the distance between the supports;

c) *Clipped infill panels* — The clips should be positioned around the periphery of the infill panel, at a maximum spacing of 600 mm. Each clip should be not less than 50 mm in length and should give a minimum depth of cover to the glass of 25 mm;

d) *Bolt fixing of glass infill panels* — Where glass is supported by bolted connections through holes in the glass, toughened/toughened laminated glass should be used; and

e) *Position of infill panels relative to the main frame* — Infill panels should be fully contained within the supporting structure. In order not to apply unintended loads to the infill panels, they should have handrails above the glass or attached to the side to which the public have access.

J-5.4.3 *Design of Free-Standing Glass Protective Railings*

The glass should be designed to satisfy the appropriate design criteria given in **J-4**. The deflection of the glass should not be more than 25 mm at any point.

J-5.4.3.1 *Handrail attachment*

Where the railing protects a difference in level greater than 600 mm, a handrail shall be used unless a laminated safety glass construction is used that remains *in-situ*, if a panel fails. Continuous fixing should be used for fixing the handrail to the glass, or individual fixings where calculations or tests demonstrate that component failure will not occur.

Where handrail is not desired, the laminated safety glass should stay in place in the event of any glass panel breakage.

The handrail should be attached to the glass in such a manner that, should a glass panel gets fractured, the handrail,

a) will remain in position; and

b) will not fail if the design load is applied across the resulting gap.

NOTE — The above condition (b) can be relaxed where the glass pane is an end pane and protects a difference in level of 600 mm or less, for example at the foot of a flight of stairs. In cases where an end pane protects a difference in level greater than 600 mm, there may normally be some adjacent structure to which the handrail could be attached, thus enabling it to meet condition (b).

J-5.4.4 *Base Fixing of Free-Standing Railings*

J-5.4.4.1 *Point of fixing clamps*

The fixing clamps on each side of the glass should be not less than 100 mm to 150 mm and should be made of a suitable metal of minimum thickness 12 mm. The number and design of fixing clamps shall be in accordance with structural requirements.

J-5.4.4.2 *Continuous fixing clamps*

The fixing clamps on each side of the glass should be not less than 100 mm wide and should be made of a suitable metal of minimum thickness 12 mm. The clamps should be continuous for the entire length of the glass pane and have a maximum bolt spacing of 500 mm.

J-5.4.4.3 *Other clamping systems*

Different clamping methods could be used, provided they cater for an effective continuous clamping over the length of the glass pane. Where a clamping system that does not rely on bolts through the glass is used, the depth over which the clamping force operates should be not less than 75 mm, unless specific tests have been carried out to prove the integrity of the system and that it meets the design criteria given.

J-5.4.4.5 *Structural movement*

The structural movement due to live or dead loads or creep of the structure to which a railing pane is clamped should be not greater than 2 mm over the length of any railing panel, if more than two bolts are used to clamp that panel.

J-5.4.4.6 *Fixing clamps*

The attachment of the fixing clamps to the structure should be capable of withstanding the turning moment induced at the fixing clamps.

J-6 IMPACT RESISTANCE AND CONTAINMENT

J-6.1 General

In addition to resisting the design loads given, glass below the minimum railing height (*see* Table 35) should also be able to resist impact forces appropriate to whether the railing indicates a route or protects people from a hazard.

J-6.2 Glass in Full Height Railings

The glass in full height railings should be selected to resist the appropriate design loads given and for its impact performance in accordance with the safety glazing recommendations.

J-6.3 Railing with Glass In-fills or Free-Standing Balustrades

The glass in railings with glass in-fills or free-standing should be selected to resist the appropriate design loads given, and to provide containment, that is, it should meet the recommended impact class without penetration.

J-7 INSTALLATION

The installation of a railing should be supervised by a suitably qualified person or persons, who should ensure that the design assumptions have been effectively implemented. Inspections and investigations should be carried out as necessary to establish the integrity of the materials and the elements of construction used.

J-7.1 Fasteners and Fittings

Fasteners and fittings should be of stainless steel, or should be hot-dip galvanized. Thin zinc plated or cadmium plated coatings should not be used for external exposure without additional protection.

J-8 MAINTENANCE

All glass should be regularly cleaned and fixings should be checked for corrosion and loosening. Maintenance recommendations, and the frequency at which railings should be inspected, are be governed by environment, usage, incidence of malicious damage and the protection applied. Protective railings assembled entirely from metal-coated steel and situated in normal environments should not require any maintenance for a very long period. They should, however, be inspected regularly and the residual coating thickness should be measured.

ANNEX K

(*Informative*)

(*Foreword*)

CONFORMITY ASSESMENT SHEET FOR GLASS AND GLAZING SYSTEM

K-1 For the purpose of conformity assessment by building regulator for glass and glazing aspects, following sheet shall be used.

Sl No. (1)	Parameters (2)	Details (3)
i) GENERAL		
	a) Building typology	
	b) Location (City, State)	
	c) Orientation	
	d) Climate zone	
	e) Window wall ratio (WWR)	
ii) GLASS		
	a) Component of building (Glass on roof/floor/wall/railing/glass fin)	
	b) Type of Glass:	
	Combination (if needed)	
	c) Tinted/Clear/Coated:	
	if yes, Side (Outer/Inner)	
	Description	
	d) Patterned/Non- patterned:	
	if yes, Side (Outer/Inner)	
	Dimension of Glass (L × B) (mm)	
	e) Thickness and Deflection:	
	Calculated Deflection as per this NBCS	
	Calculated Thickness (mm) as per this NBCS	
	Actual Thickness (mm)	
	Glass specifications as per this NBCS	**Yes/No**
	f) Safety:	

Sl No.	**Parameters**	**Details**
(1)	(2)	(3)
	Glass Height from Ground	
	Presence of Residual Protection? (Yes / No)	
	Presence of Window Restrictor for children?	
	Anti-Fallout norms followed? (Yes / No)	
	Safety glass norms followed as per this NBCS	**Yes/No**
	g) Energy Performance:	
	U-value	
	SHGC/Solar factor	
	Visible light transmittance (VLT)	
	Shading co-efficient	
iii) FRAME		
	a) Thickness	
	b) Dimension

	d) Glazing systems — Structural aspects	Yes/No
	e) Glazing systems — Fire resistance (if applicable)	Yes/No
	f) Glazing systems — Acoustics	Yes/No

LIST OF STANDARDS

The following list records those standards which are acceptable as ‘good practice’ and ‘accepted standards’ in the fulfilment of the requirements of this NBCS. The latest version of a standard shall be adopted at the time of enforcement of this NBCS. The standards listed may be used for conformance with the requirements of the referred clauses in this NBCS.

In the following list, the number appearing in the first column within parentheses indicates the number of the reference in this Section:

	IS No.	*Title*
(1)	IS 14900 : 2018	Transparent float glass — Specification (*first revision*)
	IS 2553 (Part 1) : 2018	Safety glass — Specification: Part 1 Architectural, building and general uses (*fourth revision*)
(2)	IS 3808 : 1979	Method of test for non-combustibility of building materials (*first revision*)

	IS 17518 (Part 1) : 2022/ ISO 3008-1 : 2019	Fire resistance tests — Door and shutter assemblies: Part 1 General requirements
	IS/ISO 3009 : 2003	Fire-resistance tests — Elements of building construction — Glazed elements
	IS 16945 : 2018	Fire resistance test for glass walls
	IS 16947 : 2018	Fire resistance tests for doors with glass panes, openable glass windows and sliding glass doors
(20)	IS 18190 : 2023	Fire resistance of perimeter fire barrier joint system — Method of tests
(21)	IS 16231 (Part 3) : 2019	Use of glass in buildings — Code of practice: Part 3 Fire and loading (*first revision*)
	IS 875	Code of Practice for design loads (other than earthquake) for buildings and structures:
	(Part 1) : 2026	Dead loads — Unit weights of building, construction and stored materials (*third revision*)
	(Part 2) : 1987	Imposed loads (*second revision*)
(22)	IS 16231 (Part 3) : 2019	Use of glass in buildings — Code of practice: Part 3 Fire and loading (*first revision*)
(23)	IS 17953 : 2023	uPVC profiles for windows and doors — Specification
(24)	IS 1038 : 1983	Specification for steel doors, windows and ventilators (*third revision*)
(25)	IS 11050 (Part 1) : 2023/ ISO 717-1 : 2020	Rating of sound insulation in buildings and of building elements: Part 1 Airborne sound insulation (*first revision*)
(26)	IS 11050 (Part 2) : 2023/ ISO 717-2 : 2020	Rating of sound insulation in buildings and of building elements: Part 2 Impact sound insulation (*first revision*)
(27)	IS 875	Code of practice for design loads (other than earthquake) for buildings and structures:
	(Part 1) : 2026	Dead loads — Unit weights of building, construction and stored materials (*third revision*)
	(Part 2) : 1987	Imposed loads (*second revision*)
	(Part 3) : 2015	Wind loads (*third revision*)
	(Part 5) : 1987	Special loads and load combinations (*second revision*)

	IS No.	*Title*
(28)	IS 733 : 2025	Wrought aluminium and aluminium alloy bars, rods, sections, extruded tubes, hollow sections and profiles for general engineering purposes — Specification (*fourth revision*)
	IS 738 : 1994	Specification for wrought aluminium alloys, drawn tube for general engineering purposes (*third revision*)
(29)	IS 6911 : 2026	Stainless steel plate, sheet and strip – Specification (*third revision*)
(30)	IS 1946 (Part 2) : 2025	Design of post-installed anchorage to concrete — Code of practice
(31)	IS 1946 (Part 5) : 20xx	Installation and on-site inspection of post-installed anchorage to concrete — Code of practice (*under preparation*)
(32)	IS 18434 : 2023	Field measurement of air permeability and water penetration through installed curtain wall, windows, doors, sliders and skylights under static air pressure difference — Method of test
(33)	IS 18459 : 2024	Water penetration of curtain walls, windows, sliders, doors and skylights by uniform static air pressure difference — Method of test
(34)	IS 18647 : 2024	Water penetration of curtain walls, windows, sliders and doors by dynamic air pressure — Method of test
(35)	IS 18268 : 2023/ ISO 9379 : 2005	Operating forces — Test methods — Doors
(36)	IS 17909 : 2022/ ISO 8274 : 2005	Windows and doors — Resistance to repeated opening and closing — Test method
(37)	IS 18473 : 2024	Wind resistance for curtain walls, windows, sliders, doors and skylights — Method of test
(38)	IS 17911 : 2022/ ISO 15099 : 2003	Thermal performance of windows, doors and shading devices — Detailed calculations
(39)	IS 17920 : 2022/ ISO 10077-2 : 2017	Thermal performance of windows, doors and shutters — Calculation of thermal transmittance — Numerical method for frames
(40)	IS 19006 : 2023/ ISO 8248 : 1985	Windows and door height windows — Mechanical tests
(41)	IS 17518 (Part 1) : 2022/ ISO 3008-1 : 2019	Fire resistance tests — Door and shutter assemblies: Part 1 General requirements
(42)	IS 16945 : 2018	Fire resistance test for glass walls
(43)	IS 16947 : 2018	Fire resistance tests for doors with glass panes, openable glass windows and sliding glass doors
(44)	IS 16978	Glass in building — Forced-entry security glazing: Part 1 Test and classification by repetitive ball drop (*first revision*)
	(Part 1) : 2022/ ISO 16936-1 : 2020	Test and classification by repetitive ball drop (*first revision*)
	(Part 2) : 2018/ ISO 16936-2 : 2005	Test and classification by repetitive impact of a hammer and axe at room temperature
	(Part 3) : 2018/ ISO 16936-3 : 2005	Test and classification by manual attack
	(Part 4) : 2018/ ISO 16936-4 : 2005	Test and classification by pendulum impact under thermally and fire stressed conditions
(45)	IS 18518 : 2023	Bullet resistant security glass — Quality and performance requirements

	IS No.	*Title*
(46)	IS 16978	Glass in building — Forced-entry security glazing:
	(Part 1) : 2022/ ISO 16936-1 : 2020	Test and classification by repetitive ball drop (*first revision*)
	(Part 2) : 2018/ ISO 16936-2 : 2005	Test and classification by repetitive impact of a hammer and axe at room temperature
(47)	IS 18472 : 2024	Air permeability for curtain walls, windows, sliders, doors and skylights — Method of test
(48)	IS 875	Code of Practice for design loads (other than earthquake) for buildings and structures:
	(Part 1) : 2026	Dead loads — Unit weights of building, construction and stored materials (*third revision*)
	(Part 2) : 1987	Imposed loads (*second revision*)
	(Part 3) : 2015	Wind loads (*third revision*)
	(Part 4) : 2021	Snow loads (*third revision*)
	(Part 5) : 1987	Special loads and load combinations (*second revision*)
	IS 1893 (Part 1) : 2016	Criteria for earthquake resistant design of structures: Part 1 General provisions and buildings (*sixth revision*)
	IS 16700 : 2023	Criteria for structural safety of tall concrete buildings *(first revision)*

INDEX OF TERMS

(Lists the terms appearing in the Part/Section of the NBCS)

A

*A*95 — Part D/Section 5A
Acceleration — Part D/Section 5A, Part D/Section 5B
Access Panel — Part E/Section 1
Access Point — Part D/Section 6
Accessibility — Part D/Section 5A, Part F
Accessory — Part D/Section 2
Accidental Loads — Part C/Section 6A, Part C/ Section 6B
*Accompanying Lo*ad — Part C/Section 6A, Part C/ Section 6B
Action — Part C/Section 6A, Part C/Section 6B
Action Effect or Load Effect — Part C/Section 6A, Part C/Section 6B
Actual Length — Part C/Section 6A
Admixtures (*Including Superplasticizer and Accelerator*) — Part C/Section 7
Air Admittance Valve — Part E/Section 2
*Air Brea*k — Part E/Section 2
Air Change per Hour (*ACPH*) — Part D/Section 1, Part F
Air Circuit Breaker (*ACB*) — Part D/Section 2
Air Conditioning — Part D/Section 3
Air Gap, Drainage — Part E/Section 2
Air Gap, Water Distribution — Part E/Section 1
Air System Balancing — Part D/Section 3
Air Valve — Part E/Section 1
Aisle — Part F
Allowable Load — Part C/Section 2
Alteration — Part A, Part F
Alternating Current Variable Voltage (*ACVV*) *Control* — Part D/Section 5A
Alternating Current Variable Voltage Variable Frequency (*ACVVVF*) *Control* — Part D/Section 5A
Altitude — Part D/Section 1
Ambient Noise — Part D/Section 4
*Anaerobic Diges*tion — Part E/Section 3
Anchor Pile — Part C/Section 2
Angle of Attack — Part C/Section 1
Angle of Inclination — Part D/Section 5B
Angular Distortion — Part C/Section 2
Annealed Fire Resistant Glass — Part C/Section 8
Annealed Glass (*see Glass*) — Part C/Section 8
Antenna — Part D/Section 6
Anti-siphon — Part E/Section 1
Apparatus — Part D/Section 2
Appliance — Part D/Section 2
Appliance Valve — Part E/Section 4
Approved — Part A
Approved Agency — Part E/Section 4
Appurtenance — Part E/Section 1
Apron — Part D/Section 5A
Area of Parking — Part D/Section 5C
As-Cut Finished Sizes — Part C/Section 8
Aspect Ratio — Part C/Section 8
Aspirator — Part E/Section 1
Assembly Buildings — Part C/Section 1
Assisted Evacuation — Part F
Atmospheric Pressure — Part D/Section 3
Atrium — Part F
Attenuation — Part D/Section 6
Audible Frequency Range — Part D/Section 4
Authorities Concerned — Part F
Authority Having Jurisdiction — Part C/Section 7, Part E/Section 1, Part E/Section 4
Authorization — Part E/Section 3
Authorized Person — Part D/Section 5A
Automatic Fire Detection and Alarm System — Part F
Automatic Operation — Part D/Section 5A
Automatic Parking System — Part D/Section 5C
Automatic Rescue Device — Part D/Section 5A
Automatic Sprinkler System — Part F
Automatic Water Spray Systems — Part F
Automobile Lift — Part D/Section 5A
Auxiliary or Emergency or Safety Brake — Part D/Section 5B

Available Head — Part E/Section 1

Available Car Area — Part D/Section 5A

A-Weighted Sound Pressure — Part D/Section 4

A-Weighted Sound Pressure Level — Part D/Section 4

Axial Flow Fan — Part D/Section 1

Axis of Measurement — Part D/Section 5A

Azimuth — Part D/Section 1

B

Backbone — Part D/Section 6

Backbone Cabling Media Distribution and Building Pathway — Part D/Section 6

Back Fill — Part C/Section 2

Back Pressure Backflow — Part E/Section 1

Back Siphonage — Part E/Section 1

Back Up — Part E/Section 2

Back-up Protection — Part D/Section 2

Back Water Valve — Part E/Section 2

Backflow — Part E/Section 1

Backflow Prevention Device — Part E/Section 1

Background Noise — Part D/Section 4

Balancing Weight — Part D/Section 5A

Balustrade — Part C/Section 8, Part D/Section 5B

Balustrade Decking — Part D/Section 5B

Bamboo — Part C/Section 3B

Bamboo Bore/GHOON Hole — Part C/Section 3B

Bamboo Clump — Part C/Section 3B

Bamboo Culm — Part C/Section 3B

Bamboo Mat Board — Part C/Section 3B

Bamboo Mat Corrugated Sheets — Part C/Section 3B

Bamboo Mat Corrugated Sheet — Part C/Section 3B

Bamboo Mat Ridge Cap (*BMRC*) — Part C/Section 3B

Bamboo Mat Veneer Composite — Part C/Section 3B

Barrel — Part E/Section 1

Barrier — Part D/Section 2

Base — Part C/Section 1, Part E/Section 1

Base Layer — Part C/Section 7

Basic Protection — Part D/Section 2

Basic Module — Part C/Section 7

Bath Room Group — Part E/Section 1, Part E/Section 2

Bather Load — Part E/Section 1

Batter Pile (*Raker Pile*) — Part C/Section 2

Battery Charging Stations — Part D/Section 2

Battery Energy Storage System (*BESS*) — Part D/ Section 2

Battery of Fixtures — Part E/Sction 2

Beads or Glazing Beads — Part C/Section 8

Beam — Part C/Section 3B, Part C/Section 6A

Beam, Built-Up-Laminated — Part C/Section 3A

Beam, Glued-Laminated — Part C/Section 3A

Bearing Capacity, Safe — Part C/Section 2

Bearing Capacity, Ultimate — Part C/Section 2

Bearing Pressure, Allowable (*Gross or Net*) — Part C/Section 2

Bearing Type Connection — Part C/Section 6A

Bed Block — Part C/Section 4

Bed Pan Washer — Part E/Section 2

Bedding — Part E/Section 1

Benching — Part E/Section 2

Binder Jetting-based 3D *Printing* — Part C/Section 7

Bite — Part C/Section 8

Biodegradable Substance — Part E/Section 3

Biomethanation — Part E/Section 3

Black Water — Part E/Section 2

Block (*Setting Block*) — Part C/Section 8

Bond — Part C/Section 4 Section 7

Bonding Conductor — Part D/Section 2

Bonding Ring Conductor (*BRC*) — Part D/Section 2

Bored Cast In-situ Pile — Part C/Section 2

Bored Compaction Pile — Part C/Section 2

Bored Pile — Part C/Section 2

Bottom Car Clearance — Part D/Section 5A

Bottom Car Run-by — Part D/Section 5A

Bottom Counterweight Run-by — Part D/Section 5A

Bottom Refuge Space — Part D/Section 5A

Box System — Part C/Section 4

Braced Member — Part C/Section 6A

Brake Load — Part D/Section 5B

Branch — Part E/Section 2

Branch Soil Pipe (*BSP*) — Part E/Section 2

Branch Soil Waste Pipe (*BSWP*) — Part E/Section 2

Branch Switch — Part D/Section 2

Branch Vent Pipe (*BVP*) — Part E/Section 2

Branch Waste Pipe (*BWP*) — Part E/Section 2

Breadth — Part C/Section 1
Break-In — Part D/Section 4
Breaking Strength — Part C/Section 3B
Break-Out — Part D/Section 4
Bressummer — Part C/Section 3A
Brightness Ratio or Contrast — Part D/Section 1
Brittle Cladding — Part C/Section 6A
Broad Band Noise — Part D/Section 4
Buckling Load — Part C/Section 6A
Buckling Strength or Resistance — Part C/Section 6A
Buffer — Part D/Section 5A
Building — Part A, Part F
Building, Height of — Part A, Part F
Building Drain-Combined — Part E/Section 2
Building Drain-Sanitary — Part E/Section 2
Building Drain-Storm — Part E/Section 2
Building Trap — Part E/Section 2
Building Energy Simulation (*BES*) — Part F, Part D/Section 3
Buildability — Part C/Section 7
Building Height — Part C/Section 5
Building Integrated Renewable Energy — Part D/Section 3
Building Line — Part A
Building Official — Part A
Building Permit — Part A
Building Sewer — Part E/Section 2
Building Sub-drain — Part E/Section 2
Building Management System (*BMS*) — Part D/Section 3, Part D/Section 6, Part F
Building Related Illnesses — Part D, Section 3, Part F
Built-up Section — Part C/Section 6A, Part C/Section 6B
Bunched — Part D/Section 2
Bundle-Column — Part C/Section 3B
Burried Direct — Part D/Section 2
Bus Bar — Part D/Section 6
Busbar Trunking System — Part D/Section 2
Business Buildings — Part C/Section 1
Buttress — Part C/Section 4
Bypass Equipotential Bonding Conductor — Part D/Section 2

C

C_{TR} — Part D/Section 4
Cable — Part D/Section 2
Cable, Fire Survival — Part D/Section 2
Cable, Flame Retardant (*FR*) — Part D/Section 2
Cable, Flame Retardant Low Smoke Halogen Free (*FR-LSH*) — Part D/Section 2
Cable, Flexible — Part D/Section 2
Cable, Metal-Sheathed — Part D/Section 2
Cable, PVC Sheathed-insulated — Part D/Section 2
Cable, Weatherproof — Part D/Section 2
Cable, XLPE — Part D/Section 2
Cable Armoured — Part D/Section 2
Cable Bracket — Part D/Section 2
Cable Channel — Part D/Section 2
Cable Cleat — Part D/Section 2
Cable Coupler — Part D/Section 2
Cable Ducting — Part D/Section 2
Cable Ladder — Part D/Section 2
Cable Raceways – Part D/Section 2
Cable Support and Fixing Materials (*Fire Survival*) — Part D/Section 2
Cable Tray — Part D/Section 2
Cable Trunking — Part D/Section 2
Cable Tunnel — Part D/Section 2
Call Indicator — Part D/Section 5A
Camber — Part C/Section 6A and 6B
Candela (*cd*) — Part D/Section 1
Capacity Factor — Part F
Capacity of Means of Egress — Part F
Car Bodywork — Part D/Section 5A
Car Door Electric Contact — Part D/Section 5A
Car Frame — Part D/Section 5A
Car Platform — Part D/Section 5A
Cartridge Fuse Link — Part D/Section 2
Category 1 *circuit* — Part D/Section 2
Category 2 *circuit* — Part D/Section 2
Category 3 *circuit* — Part D/Section 2
Catwalk — Part F
Ceiling Rose — Part D/Section 2
Cell — Part C/Section 3B
Cellular Concrete — Part C/Section 7

Cellulose — Part C/Section 3B
Central Field – Part D/Section 1
Centre Internode — Part C/Section 3B
Centrifugal Fan — Part D/Section 1
Cesspool — Part E/Section 2
Chair — Part E/Section 1
Chair Rail — Part C/Section 8
*Channe*l — Part E/Section 1
Characteristic Load — Part C/Section 6A, Part C/Section 3B, Part C/Section 6B
Characteristic Strength — Part C/Section 3B
Characteristic Yield/Ultimate Stress — Part C/ Section 6A
Check — Part C/Section 3A
Circadian Lightning — Part D/Section 1
Circuit — Part D/Section 2
Circuit, Final Sub — Part D/Section 2
Circuit Breaker — Part D/Section 2
Circuit Breaker, Linked — Part D/Section 2
Circulating Hot Water System — Part E/Section 1
Clay — Part C/Section 2
Clay, Firm — Part C/Section 2
Clay, Soft — Part C/Section 2
Clay, Stiff — Part C/Section 2
Cleaning Eye — Part E/Section 2
Clear Design Sky — Part D/Section 1
Clear Glass — Part C/Section 8
Clear Waste Water — Part E/Section 2
Cleavability — Part C/Section 3B
Closely-spaced Modules — Part C/Section 1
Coaxial Cable — Part D/Section 6
Coefficient of Linear Expansion — Part C/Section 8
Coefficient of Performance, Compressor, Heat Pump — Part D/Section 3
Coefficient of Performance, Compressor, Refrigerating — Part D/Section 3
Coefficient of Performance (*Heat Pump*) — Part D/Section 3
Coefficient of Performance (*Refrigerating*) — Part D/Section 3
Collapse — Part C/Section 3B
Collection — Part E/Section 3
Collection Chamber — Part E/Section 2
Colour Rendering Index (*CRI*) — Part D/Section 1
Column — Part C/Section 1, Part C/Section 3B, Part C/Section 6A, Part C/Section 4
Comb — Part D/Section 5B
Comb Lighting — Part D/Section 5B
Comb Plate — Part D/Section 5B
Comb Plate Switch — Part D/Section 5B
Comb Teeth — Part D/Section 5B
Combined Piled Raft Foundation — Part C/Section 2
Combined System — Part E/Section 2
Combustible Material — Part F, Part C/Section 8
Common Path of Travel — Part F
Common Rafter — Part C/Section 3B
Communication Pipe — Part E/Section 1
Compact Section — Part C/Section 6A
Compact Substation or Prefabricated Substation — Part D/Section 2
Compensation Means — Part D/Section 5A
Competent Authority — Part E/Section 4
Competent Maintenance Person — Part D/ Section 5A, Part D/Section 5B
Competent Official — Part A
Component — Part C/Section 7
Composite Action — Part C/Sec 6 B
Composite Station — Part F
Composite Members — Part C/Section 7
Composting — Part E/Section 3
Compression Wood — Part C/Section 3A
Concrete buildings — Part C/Section 1
Concourse — Part F
Conductor of a Cable or Core — Part D/Section 2
Conductor, Aerial — Part D/Section 2
Conductor, Bare — Part D/Section 2
Conductor, Earthed — Part D/Section 2
Conductor, Insulated — Part D/Section 2
Conduit — Part D/Section 2
Connection — Part E/Section 2
Connecting Structure — Part C/Section 5
Connector — Part D/Section 2
Connector Box or Joint Box — Part D/Section 2
Connector for Portable Appliances — Part D/ Section 2
Consolidation Point (*CP*) — Part D/Section 6

Constant Stress Range — Part C/Section 6A

Construction and Demolition Waste — Part E/ Section 3

Consumer — Part E/Section 1, Part E/Section 2

Consumer's Pipe — Part E/Section 1

Consumer's Terminals — Part D/Section 2

Contaminants — Part D/Section 1

Continuous Operating Voltage (U_c) — Part D/Section 2

Continuous pressure operation — Part D/ Section 5A

Control — Part D/Section 5A

Conversion — Part A

Concrete for 3D Printing — Part C/Section 7

Cooling Load — Part D/Section 3

Cooling Tower — Part D/Section 3

Cord, Flexible — Part D/Section 2

Core of a Cable — Part D/Section 2

Core — Part C/Section 5

Core and Outrigger Structural System — Part C/Section 5

Core, Outrigger and Belt Wall System — Part C/Section 5

Correlated Colour Temperature (*CCT*) — Part D/Section 1

Corridor — Part C/Section 8

Corrosion — Part C/Section 6A

Counterweight — Part D/Section 5A

Cover — Part E/Section 1

Components — Part C/Section 7A

Covered Area — Part F

Coupled Structural Wall Building — Part C/Section 5

Coupled Glazing (*Secondary Glazing*) — Part C/Section 8

Crack Mouth Opening Displacement (*CMOD*) — Part C/Section 5

Crack Opening Displacement (*COD*) — Part C/Section 5

Crane Load — Part C/Section 6A

Crookedness — Part C/Section 3B

Cross Wall — Part C/Section 3B

Cross-connect — Part D/Section 6

Cross-Connection — Part E/Section 1

Cross-Sectional Area of Masonry Unit — Part C/Section 4

Cross-Talk — Part D/Section 4

Crown of Trap — Part E/Section 2

Crumple Section — Part C/Section 4

Crush Train Load — Part F

Cumulative Fatigue — Part C/Section 6A

Current Carrying Capacity of a Conductor — Part D/Section 2

Current using Equipment — Part D/Section 2

Curtain Wall — Part C/Section 4, Part C/Section 8

Curtain Wall Assembly — Part C/Section 8

Curvature — Part C/Section 3B

Customer's/Consumer's Connection — Part E/ Section 4

Cut-Out — Part D/Section 2

Cut-Off Level — Part C/Section 2

Cut-Off Limit — Part C/Section 6A

D

Damp Situation — Part D/Section 2

Danger — Part D/Section 2

Datacentre — Part D/Section 2

Daylight Area — Part D/Section 1

Daylight Factor — Part D/Section 1

Daylighting — Part D/Section 1

Daylight Penetration — Part D/Section 1

Deconstruction — Part C/Section 6A

Deconstruction (*or Disassembly, or Demounting*) — Part C/Section 6A

Design for Deconstruction (*DfD*) — Part C/Section 6A

De-structured Bamboo — Part C/Section 3B — Part D/ Section 2

Dead -end — Part F

Dead -end Travel — Part F

Dead Knot — Part C/Section 3A

Dead Zone Length — Part C/Section 7

Dead Loads — Part C/Section 6A

Decay or Rot — Part C/Section 3A

Decayed Knot — Part C/Section 3A

Decibel — Part D/Section 4

Dedicated Outdoor Air System (*DOAS*) — Part D/Section 3

Deep Area — Part E/Section 1

Deep Manhole – Part E/Section 2
Deflection — Part C/Section 6A
Deflector Sheave — Part D/Section 5A
Delamination — Part C/Section 3B
Demand Based Ventilation — Part D/Section 3
Demand Recirculation Water System — Part E/Section 1
Demolition Permit — Part A
Depth — Part C/Section 1
Depth of Manhole — Part E/Section 2
Design Acceleration — Part C/Section 1, Part D/Section 5A
Design Acceleration Spectrum — Part C/Section 1
Design Current (*of a Circuit*) — Part D/Section 2
Design Food Elevation — Part E/Section 1
Design Life — Part C/Section 6A
Design Service Life — Part C/Section 6B
Design Load — Part C/Section 2
Design Load/Factored Load — Part C/Section 6A, Part C/Section 6B
Design Pressure Difference — Part D/Section 3
Design Spectrum — Part C/Section 6A
Design Stress — Part C/Section 2
Design Horizontal Force — Part C/Section 1
Detail Category — Part C/Section 6A, Part C/Section 6B
Developed Height — Part C/Section 1
Developed Length — Part E/Section 2
Development — Part A
Development Permit — Part A
Dew Point Temperature — Part D/Section 3
Diameter — Part E/Section 2
Diameter of Knot — Part C/Section 3A
Diaphragm — Part C/Section 1, Part C/Section 7
Diaphragm, Structural — Part C/Section 3A
Differential Settlement of CPRF (*Spr, Diff*) — Part C/Section 2
Differential Shrinkages — Part C/Section 6B
Dilution Ventilation — Part D/Section 1
Direct Acting Lift — Part D/Section 5A
Direct Contact — Part D/Section 2
Distributed Antenna System (*DAS*) — Part D/*Section* 6
Direct to Home (*DTH*) — Part D/Section 6
Directions in the Printed Specimens — Part C/Section 7
Direct Solar Illuminance — Part D/Section 1
Direct Tap — Part E/Section 1
Discolouration — Part C/Section 3A, Part C/Section 3B
Disconnector — Part D/Section 2
Discontinuity — Part C/Section 6A
Discrimination (*Selectively-Over-Current Discrimination*) — Part D/Section 2
Disposal — Part E/Section 3
Distance Piece — Part C/Section 8
Distance Area or Resistance Area (*for an Earth Electrode only*) — Part D/Section 2
Distribution/Distributing Company — Part E/ Section 4
Diversity Factor — Part D/Section 2
Diving Pool — Part E/Section 1
Door Pre-opening Time/Advanced Door Opening Time — Part D/Section 5A
Door-to-Door Time — Part D/Section 5A
Door or Shutter Assembly Door-Set — Part C/Section 8
Door Closer — Part D/Section 5A
Door Closing Time — *Part D*/Section 5A
Door Closing Delay Time — *Part D*/Section 5A
Door Opening Time — Part D/Section 5A
Door Operator — Part D/Section 5A
Door (*Lift Landing Door and Lift Car Door*) — Part D/Section 5A
Door, Centre Opening Sliding — Part D/Section 5A
Door, Mid-Bar Collapsible — Part D/Section 5A
Door, Multi-Panel — Part D/Section 5A
Door, Single Slide — Part D/Section 5A
Door, Swing — Part D/Section 5A
Door, Two Speed Siding — Part D/Section 5A
Door, Vertical Bi-parting — Part D/Section 5A
Door, Vertical Lifting — Part D/Section 5A
Double Glazed Fire Resistant Glass — Part C/Section 8
Double Glazing — Part C/Section 8
Down-Comer — Part F
Down-Direction Valve — Part D/Section 5A
Down Take Tap — Part E/Section 1
Drain — Part A, Part E/Section 2

Drain Vent Pipe (*DVP*) — Part E/Section 2
Drainage — Part A, Part E/Section 2
Drainage Fixture Unit (*DFU*) — Part E/Section 2
Drainage Work — Part E/Section 2
Drinking Water Fountain — Part E/Section 1
Drive Way — Part D/Section 5C
Drive Control System — Part D/Section 5A
Driven Cast in-situ Pile — Part C/Section 2
Drop Connection — Part E/Section 2
Drop Manhole — Part E/Section 2
Dry Riser — Part F
Dry Bulb Temperature — Part D/Section 1, Part D/Section 3
Duct — Part D/Section 2
Ducting — Part D/Section 2
Duct System — Part D/Section 3
Ductility — Part C/Section 6A
Dumb Waiter — Part D/Section 5A
Durability — Part C/Section 6A
Duration of Load — Part C/Section 3A
Dwellings — Part C/Section 1

E

Earth — Part D/Section 2
Earth Continuity Conductor — Part D/Section 2
Earthed Concentric Wiring — Part D/Section 2
Earth Electrode — Part D/Section 2
Earth Electrode Network — Part D/Section 2
Earth Electrode Resistance — Part D/Section 2
Earth Fault — Part D/Section 2
Earth Fault Current — Part D/Section 2
Earth Fault Loop Impedance (Z_s) — Part D/Section 2
Earthing — Part D/Section 2
Earthing Conductor — Part D/Section 2
Earthing Lead — Part D/Section 2
Earth Leakage Current — Part D/Section 2
Earthing Resistance, Total — Part D/Section 2
Earthquake Effects — Part C/Section 6A
Earthquake Loads — Part C/Section 6A
Economizer, Air — Part D/Section 3
Economizer, Water — Part D/Section 3
Eco-Toilet (*or Bio Toilet*) — Part E/Section 2
Edge Distance — Part C/Section 3A, Part C/Section 6A
Edge Deterioration — Part C/Section 8
Edge Faults — Part C/Section 8
Edge Polished — Part C/Section 8
Edging — Part C/Section 8
Educational Buildings — Part C/Section 1
Effective Frontal Area — Part C/Section 1
Effective Height — Part C/Section 4
Effective Lateral Restraint – Part C/Section 6A
Effective Length — Part C/Section 4, Part C/Section 6A
Effective Opening — Part E/Section 1
Effective Perceived Noise Level in Decibel (*EPN dB*) — Part D/Section 4
Effective Temperature (*ET*) — Part D/Section 1, Part D/Section 3
Effective Thickness — Part C/Section 4
Efficiency of a Pile Group — Part C/Section 2
Egress Lighting — Part F
Elastic Cladding — Part C/Section 6A
Elastic Critical Moment — Part C/Section 6A
Elastic Design — Part C/Section 6A
Elastic Force Reduction Factor — Part C/Section 1
Elastic Limit — Part C/Section 6A
Electric Safety Chain — Part D/Section 5A
Electric Shock — Part D/Section 2
Electric Vehicle (*EV*) — Part D/Section 2
EV Connector — Part D/Section 2
Electric Vehicle Supply Equipment (*EVSE*) — Part D/Section 2
Electrical Anti-Creep System — Part D/Section 5A
Electrical and Mechanical Interlock — Part D/Section 5A
Electrical Equipment (*abb: Equipment*) — Part D/Section 2
Electrically Independent Earth Electrodes — Part D/Section 2
Electrical Safety Devices — Part D/Section 5B
Electrical Safety System — Part D/Section 5B
Electrical Supply System for Life and Safety Services — Part D/Section 2
Electro-mechanical Lock — Part D/Section 5A
Electronic Control — Part D/Section 5A
Electronic Devices — Part D/Section 5A

Electromechanical Parking Systems — Part D/Section 5C
Element of Surface Area — Part C/Section 1
Embodied Carbon — Part C/Section 6A
Emergency Floor Drain — Part E/Section 2
Emergency Lighting — Part F
Emergency Lighting System — Part F
*Emergency Stop S*witch — Part D/Section 5B
Emergency Switching — Part D/Section 2
Emulative Detailing System — Part C/Section 7
Enclosed Station — Part F
Enclosed Distribution Board — Part D/Section 2
Enclosure — Part D/Section 2
*End Dis*tance — Part C/Section 3A, Part C/Section 3B, Part C/Section 6A
End Splitting — Part C/Section 3B
Energy Accumulation Type — Part D/Section 5A
Energy Dissipation Type — Part D/Section 5A
Energy Efficiency Ratio (*EER*) — Part D/Section 3
Energy Recovery Unit — Part D/Section 3
Entraining Load — Part F
Entrance Bias — Part D/Section 5A
Entrance Floor — Part D/Section 5A
Environmental Product Declaration (*EPD*) — Part C/Section 6A
Equipotential Bonding — Part D/Section 2
Equivalent Continuous A-Weighted Sound Pressure Level, $L_{Aeq.T}$ — Part D/Section 4
Equivalent Sound Absorption Area of a Room, *A* — Part D/Section 4
Equivalent Sound Pressure Level (L_{Aeq}) — Part D/Section 5A, Part D/Section 5B
Erection Loads — Part C/Section 6A
Erection Tolerance — Part C/Section 6A
Escalator — Part D/Section 5B
Escape Lighting — Part F
Evacuation Lift — Part F, Part D/Section 5A
Evacuation Exit Lobby (*EEL*) — Part D/Section 5A
Evacuation Time — Part F
Evaporative Cooling — Part D/Section 3
Exhaust of Air — Part D/Section 1
Existing Lift — Part D/Section 5A
Exit — Part F
Exit Access — Part F
Exit Access Corridor — Part F
Exit Discharge — Part F
Exit Door, Height — Part F
Exit Handling Capacity — Part F
Exit Signages — Part F
Exit Stairway, External — Part F
Exit Stairway, Internal — Part F
Exit Width, Clear — Part F
Exit Width, Maximum — Part F
Exit Width, Minimum — Part F
Exit, Doorway — Part F
Exit, External Ramp — Part F
Exit, Half a Unit Width – Part F
Exit, Horizontal — Part F
Exit, Passageway — Part F
Exit, Ramp — Part F
Extracted Specimen — Part C/Section 7
Exit, Roof — Part F
Exit, Separation — Part F
Exit, Stairway — Part F
Exit, Tunnel — Part F
Exit, Unit Width — Part F
Extrudability — Part C/Section 7
Exit, Width — Part F
Exothermic Welding — Part D/Section 2
Exposed Conductive Part — Part D/Section 2
Exposed Edge — Part C/Section 8
Exposed Metal — Part D/Section 2
Exposed Surface Area to Mass Ratio — Part C/Section 6A
Express Zone — Part D/Section 5A
Exterior Panel — Part D/Section 5B
External (*Exterior*) *Exit Stairway* — Part F
External Influence — Part D/Section 2
External Reflected Component (*ERC*) — Part D/Section 1
Extraneous Conductive Part — Part D/Section 2
Extrusion-based Concrete 3D Printing — Part C/Section 7

F

Fabrication Tolerance — Part C/Section 6A
Facade — Part C/Section 8
Facade Level — Part D/Section 4
Faced Wall — Part C/Section 4
Faceted Glazing — Part C/Section 8
Factor of Safety — Part C/Section 6A
Factor of Safety (*With Respect to Bearing Capacity*) — Part C/Section 2
Fatigue — Part C/Section 6A, Part C/Section 6B
Fatigue Limit State — Part C/Section 6B
Fatigue Loading — Part C/Section 6A,
Fatigue Strength — Part C/Section 6A, Part C/Section 6B
Fault — Part D/Section 2
Fault Current — Part D/Section 2
Fault Protection — Part D/Section 2
Feed Cistern — Part E/Section 1
Fenestration — Part C/Section 8
Fetch Length — Part C/Section 1
Fin — Part C/Section 8
Filament — Part C/Section 7
Final Circuit — Part D/Section 2
Finger Joint — Part C/Section 3A
Finger Jointed Timber — Part C/Section 3A
Fire Barrier (*or Fire Resisting Barrier*) — Part F
Fire Compartment — Part F
Fire Command Centre (*FCC*) — Part F
Fire Damper — Part D/Section 3
Fire or Fire/Smoke Damper — Part F
Fire Door and Fire Door Assembly — Part F
Fire Door Assembly, Fire Resistance Rating — Part F
Fire Enclosure — Part F
Fire Exit — Part F
Fire Exit Hardware — Part F
Fire Exposure Condition — Part C/Section 6A and 6B
Firefighting shaft (*Fire Tower*) — Part F
Firefighter Access Panel — Part F
Fireman's Lift — Part F
Fire Load — Part F
Fire Load Density — Part F
Fire Prevention — Part F
Fire Protection System — Part C/Section 6A
Fire Resistance — Part F, Part C/Section 6A
Fire Resistance Level — Part C/Section 6A
Fire Resistance Rating — Part F
Fire Resistant Wall — Part F
Fire Separation — Part F, Part C/Section 8
Fire Stop — Part F
Fire Stop Assembly for Joints — Part F
Fire Stop Assembly for Penetrations — Part F
Fire Suppression Systems — Part F
Fire Survival Distribution Board — Part D/Section 2
Fire Tower — Part F
Fire Wall or Fire Separating Wall — Part F
Fish Wire — Part D/Section 2
Fitting, Lighting — Part D/Section 2
Fittings — Part E/Section 1, Part E/Section 2
Fixed Equipment — Part D/Section 2
Fixture Unit — Part E/Section 1, Part E/Section 2
Flameproof Enclosure — Part D/Section 2
Flattened Bamboo — Part C/Section 3B
Flight Time — Part D/Section 5A
Flexible Shear Connector — Part C/Section 6 B
Flexural Stiffness — Part C/Section 6A
Float Glass — Part C/Section 8
Float Operated Valve — Part E/Section 1
Flood Level Rim — Part E/Section 1, Part E/Section 2
Floor Area (*Gross*) — Part F
Floor Area Ratio (*FAR*) — Part F
Floor Area (*Net*) — Part F
Floor Levelling Switch — Part D/Section 5A
Floor Stopping Switch — Part D/Section 5A
Flow Pressure — Part E/Section 1
Flush Over Panel — Part C/Section 8
Flushing Cistern — Part E/Section 1
Flushometer Tank — Part E/Section 1
Foam Protection System — Part F
Footing — Part C/Section 2
Foyer — Part F
Force Coefficient — Part C/Section 1
Formation — Part E/Section 1, Part E/Section 2
Foundation — Part C/Section 2

Foundation, Raft — Part C/Section 2
Frame — Part C/Section 8
Frame Building — Part C/Section 5
Framed-Tube System — Part C/Section 5
Frameless Glazing — Part C/Section 8
Free-Field Level — Part D/Section 4
French Drain or Rubble Drain — Part E/Section 2
Frequency — Part D/Section 4, Part D/Section 6
Fresh Air or Outside Air — Part D/Section 1
Friction Type Connection — Part C/Section 6A
Front Putty — Part C/Section 8
Frost Line — Part E/Section 1, Part E/Section 2
Full Culm — Part C/Section 3B
Full Load Pressure — Part D/Section 5A
Fully Framed Glazing — Part C/Section 8
Functional Earthing — Part D/Section 2
Fundamental or Ultimate Stress — Part C/Section 3A, Part C/Section 3B

G

Gap — Part C/Section 8
Gas Fitter — Part E/Section 4
Gas-Based Suppression Systems — Part F
Gauge — Part C/Section 6A
Geared Machine — Part D/Section 5A
Gearless Machine — Part D/Section 5A
General Ventilation — Part D/Section 1
General Washing Place — Part E/Section 1
Generator of Wastes — Part E/Section 3
Geothermal Heat Pump — Part D/Section 3
Geyser — Part E/Section 1
Glare — Part D/Section 1
Glass — Part C/Section 8
Glass Appearance Faults — Part C/Section 8
Glazing — Part C/Section 8
Glazing-bite — Part C/Section 8
Glide — Part D/Section 3
Global Warming Potential (*GWP*) — Part D/Section 3
Globe Temperature — Part D/Section 1
Glue — Part C/Section 3A
Glued Laminated (*Glulam*) — Part C/Section 3A
Glued Laminated, Horizontally — Part C/Section 3A
Glued Laminated, Vertically — Part C/Section 3A
Goods Lift — Part D/Section 5A
Gradient Height — Part C/Section 1
Gravel — Part C/Section 2
Gravity Columns — Part C/Section 5
Gravity Load — Part C/Section 6A
Grease Interceptor (*or Grease Trap*) — Part E/Section 2
Grey water — Part E/Section 2
Grid — Part D/Section 5C
Gridded Water Distribution System — Part E/Section 1
Ground Improvement — Part C/Section 2
Ground Roughness — Part C/Section 1
Ground-Borne Noise — Part D/Section 4
Group Automatic Operation — Part D/Section 5A
Grout — Part C/Section 4
Grouted Cavity Reinforced Masonry — Part C/Section 4
Grouted Hollow-unit Masonry — Part C/Section 4
Grouted Masonry — Part C/Section 4
Grouted Multi-Wythe Masonry — Part C/Section 4
Guard Rail — Part C/Section 8
Guide Rails — Part D/Section 5A
Guide Rails Fixing — Part D/Section 5A
Guide Shoe — Part D/Section 5A
Gully Chamber — Part E/Section 2
Gully Trap — Part E/Section 2
Gusset Plate — Part C/Section 6A
Gust — Part C/Section 1

H

Hairline Scratch — Part C/Section 8
Halo — Part C/Section 8
Hand-Held Equipment — Part D/Section 2
Handling Capacity (*HC*) — Part D/Section 5A
Handrail — Part D/Section 5B, Part F
Hardening Behaviour – Part C/Section 5
Harmonics (*Current and Voltage*) — Part D/Section 2
Haunching — Part E/Section 1
Hazardous Live-Part — Part D/Section 2
Hazardous Material — Part F
Headway — Part F

Heat Pump — Part D/Section 3
Heat Recovery — Part D/Section 3
Heat Soaking — Part C/Section 8
Heat Strengthened Glass — Part C/Section 8
Heating Load — Part D/Section 3
Headroom/Overhead — Part D/Section 5A
Heel Rest Bend or Duck-foot Bend — Part E/Section 1
Hemi Cellulose — Part C/Section 3B
Hermetic Seal — Part C/Section 8
High Activity Area — Part C/Section 8
High Altitudes — Part E/Section 1, Part E/Section 2
High Rise Building — Part F
High Risk Area — Part C/Section 8
High Shear — Part C/Section 6A
Highway Authority — Part E/Section 1, Part E/Section 2
Hoisting Beam — Part D/Section 5A
Hollow Unit — Part C/Section 4
Home Lift — Part D/Section 5A `
Horizontal Cabling — Part D/Section 6
Horizontal Cabling Media Distribution and Building Pathway — Part D/Section 6
Horizontal Cross-connect (*HC*) — Part D/Section 6
Horizontal Exit — Part F
Horizontal Movements — Part D/Section 5C
Horizontal Pipe — Part E/Section 1, Part E/Section 2
Hospital Lift — Part D/Section 5A
Hot Water Tank — Part E/Section 1
Humidification — Part D/Section 1
Humidity, Absolute — Part D/Section 1
Humidity, Relative — Part D/Section 1
Hybrid Building — Part D/Section 3
Hydrant System — Part F
Hydraulic Lift — *Part D/Section* 5*A*
Hydraulic Parking System — *Part D/Section* 5*C*
Hydro-pneumatic Systems — Part E/Section 1
Hydronic Systems — Part D/Section 3
Hydronic System Balancing — Part D/Section 3

I

Illuminance — Part D/Section 1
Impact Sound Pressure Level, L_i — Part D/Section 4
Imposed Load (*Live Load*) — Part C/Section 1, Part C/Section 6A
Impulse Current — Part D/Section 2
Impulse Withstand Voltage — Part D/Section 2
In Building Solution (*IBS*) — Part D/Section 6
Increments — Part C/Section 7
Incidental Occupancy within Station — Part F
Incoming Traffic — Part D/Section 5A
Indirect Acting Lift — Part D/Section 5A
Indirect Contact — Part D/Section 2
Indirect-Direct Cooling — Part D/Section 3
Indirect Waste Pipe — Part E/Section 2
Indoor Air Quality (*IAQ*) — Part D/Section 3
Indoor Ambient Noise — Part D/Section 4
Indoor Artificial Lighting — Part D/Section 1
Industrial Buildings — Part C/Section 1
Industrial Plugs and Sockets — Part D/Section 2
Infill Balustrades — Part C/Section 8
Infiltration/Exfiltration — Part D/Section 3
Inflammable Material — Part D/Section 2
Initial Dead Load — Part C/Section 6B
Initial Load Test — Part C/Section 5B
Injection — Part C/Section 2
Inlet — Part E/Section 1
Inlet Fittings — Part E/Section 2
Inlet Hopper — Part E/Section 2
Inner Diameter — Part C/Section 3B
Insanitary — Part E/Section 2
Insertion Loss — Part D/Section 4
Inside Location — Part C/Section 3A, Part C/Section 3B
Inside Plant (*ISP*) — Part D/Section 6
Inspection Chamber — Part E/Section 2
Inspection Door — Part D/Section 5B
Inspector — Part D/Section 5A
Instability — Part C/Section 6A
Installation — Part D/Section 5A, Part E/Section 4, Part D/Section 5B
Installation (*Electrical*) — Part D/Section 2
Installer — Part D/Section 5A, Part D/Section 5B
Instantaneous Safety Gear — Part D/Section 5A

Integrated Fire Safety System — Part F
Institutional Buildings — Part C/Section 1
Insulated — Part D/Section 2
Insulating Glass Unit (*IGU*) — Part C/Section 8
Insulation — Part D/Section 2
Insertion Loss (*LIL*) — Part D/ Section 4
Insulation, Basic — Part D/Section 2
Insulation, Double — Part D/Section 2
Insulation, Reinforced — Part D/Section 2
Insulation, Supplementary — Part D/Section 2
Interceptor — Part E/Section 2
Interceptor Manhole or Interceptor Chamber — Part E/Section 2
Inter Floor Traffic — Part D/Section 5A
Interior Panel — Part D/Section 5B
Interlayer — Part C/Section 8
Intermediate Cross-Connect — Part D/Section 6
Internal (*Interior*) *Exit Stairway* — Part F
Internal Partition — Part C/Section 8
Internal Reflected Component (*IRC*) — Part D/ Section 1
Interval — Part D/Section 5A
Invert — Part E/Section 2
Inverter — Part D/Section 2
Internet of Things — Part D/Section 6
Isolation — Part D/Section 2
Isolator — Part D/Section 2
Isoptera — Part C/Section 3A

J

Jack — Part D/Section 5A
Jerk — Part D/Section 5A
Joint — Part C/Section 1, Part C/Section 3B, Part C/Section 4
Joist — Part C/Section 3B
Jointed Detailing System — Part C/Section 7
Joint Reinforcement — Part C/Section 4
Junction Box — Part D/Section 2
Junction Pipe — Part E/Section 1, Part E/Section 2

K

Key Elements — Part C/Section 5
Knot — Part C/Section 3A
Knot Hole — Part C/Section 3A

L

Lagging — Part E/Section 1, Part E/Section 2
Lamella Roof — Part C/Section 3A
Laminated Glass — Part D/Section 5A
Layer — Part C/Section 7
Laminated Safety Glass — Part C/Section 8
*Laminated Veneer Lumbe*r — Part C/Section 3A
Laminations — Part C/Section 3A
Landfilling — Part E/Section 3
Landing Call Push — Part D/Section 5A
Landing Door — Part D/Section 5A
Landing Zone — Part D/Section 5A
Large CPRF — Part C/Section 2
Large Lobby — Part D
Large Lobby at the Level of Exit Discharge — Part F
Latent Heat — Part D/Section 3
Latent Heat Load — Part D/Section 3
Lateral Force-Resisting System (*LFRS*) — Part C/ Section 1
Lateral Restraint for a Beam — Part C/Section 6A
Lateral Support — Part C/Section 4
Latewood — Part C/Section 3A
Leachate — Part E/Section 3
Leading Imposed Load — Part C/Section 6A
Leaf — Part C/Section 4
Leakage Current — Part D/Section 2
Length of Internode — Part C/Section 3B
Levelling — Part D/Section 5A
Levelling Accuracy — Part D/Section 5A
Levelling Zone — Part D/Section 5A
Levelling Device, Lift Car — Part D/Section 5A
Levelling Device, One Way Automatic — Part D/Section 5A
Levelling Devices — Part D/Section 5A
Levelling Device, Two-Way Automatic Maintaining — Part D/Section 5A
Levelling Device, Two-way Automatic Non-maintaining — Part D/Section 5A
Levelling Zone — Part D/Section 5A
LEMP Protection Measures (*SPM*) — Part D/ Section 2

License — Part D/Section 5*A*

Licensed (*or Registered*) *Plumber* — Part E/Section 1, Part E/Section 2

Lift — Part D/Section 5A

Lift Car — Part D/Section 5A

Lift Landing — Part D/Section 5A

Lift Lobby — Part F

Lift Machine — Part D/Section 5A

Lift Pit — Part D/Section 5A

Lift Ride Quality — Part D/Section 5A

Lift Well — Part D/Section 5A

Lift Well Enclosure — Part D/Section 5A

Light Output Ratio (*LOR*) *or Efficiency* — Part D/ Section 1

Light Pipe — Part D/Section 1

Light Shelf — Part D/Section 1

Light Transmission — Part C/Section 8

Light Transmittance — Part C/Section 8

Light-Weight Concrete — Part C/Section 7

Lighting — Part D/Section 1

Lightning Electromagnetic Impulse — Part D/ Section 2

Lightning Protection — Part D/Section 2

Lightning Protection Level (*LPL*) — Part D/Section 2

Lightning Protection Zone — Part D/Section 2

Lightning Protection System (*LPS*) — Part D/Section 2

Lightning Protection System, External — Part D/Section 2

Lightning Protection System, Internal — Part D/Section 2

Lignin — Part C/Section 3B

Limit State — Part C/Section 6A & 6B

Limiting Capacity — Part C/Section 2

Line Conductor — Part D/Section 2

Linear Defects — Part C/Section 8

Linking Beams (*Also called Coupling Beams*) — Part C/Section 5

Link Load — Part F

Liquefaction — Part C/Section 1 and 2

Live Knot — Part C/Section 3A

Live or Alive — Part D/Section 2

Live Load — Part C/Section 6A

Live Part — Part D/Section 2

Loads — Part C/Section 6A and 6B

Load Bearing Member — Part D/Section 5A

Load Bearing Wall — Part C/Section 4

Load Eccentricity (*eL or eB*) — Part C/Section 2

Loaded Edge Distance — Part C/Section 3A

Loaded End or Compression End Distance — Part C/Section 3B

Local Area Network (*LAN*) — Part D/Section 6

Local Exhaust Ventilation — Part D/Section 1

Local Multipoint Distribution System (*LMDS*) — Part D/Section 6

Location — Part C/Section 3A

Locations, Industrial — Part D/Section 2

Locations, Non-Industrial — Part D/Section 2

Locking Devices — Part D/Section 5C

Loose Grain (*Loosened Grain*) — Part C/Section 3A

Loose Knot — Part C/Section 3A

Lower Inner Decking — Part D/Section 5B

Lower Outer Decking — Part D/Section 5B

Low Rise Building — Part C/Section 1

Low-Voltage Switchgear and Controlgear Assembly — Part D/Section 2

Lumen — Part D/Section 1

Luminaire — Part D/Section 2

Luminance (*At a point of a Surface in a Given Direction*) (*Brightness*) — Part D/Section 1

Luminous Flux — Part D/Section 1

M

m-k Factor — Part C/Section 6 B

Machette — Part C/Section 3B

Machine Room — Part D/Section 5A

Machine Room Less Lift — Part D/Section 5A and 5B

Machine to Machine (*M2M*) *Communication* — Part D/Section 6

Machinery — Part D/Section 5A and 5B

Material Efficiency — Part C/Section 6

Machinery Spaces — Part D/Section 5A and 5B

Maximum Capacity — Part D/Section 5B

Maximum CPRF Settlement (*Spr,Max*) — Part C/Section 2

Made-Up Ground — Part C/Section 2

Main Cross-connect — Part D/Section 6

Main Distribution Frame (*MDF*) — Part D/Section 6
Main Drain — Part E/Section 1
Main Earthing Terminal — Part D/Section 2
Main Member — Part C/Section 6A
Main Soil Pipe (*MSP*) — Part E/Section 2
Main Soil and Waste Pipe (*MSWP*) — Part E/Section 2
Main Vent Pipe (*MVP*) — Part E/Section 2
Main Waste Pipe (*MWP*) – Part E/Section 2
Maintenance — Part D/Section 5A, Part D/Section 5B
Maintenance Factor — Part D/Section 1
Maintenance Organization — Part D/Section 5A and 5B
Make-Up Air — Part D/Section 1
Make-Up Water — Part E/Section 1
Manhole — Part E/Section 2
Manhole Chamber — Part E/Section 2
Manifestation — Part C/Section 8
Manifold — Part E/Section 4
Manufacturer — Part D/Section 5A, Part D/Section 5B
Masonry — Part C/Section 4
Masonry Buildings — Part C/Section 1
Masonry Unit — Part C/Section 4
Mass Rapid Transit — Part F
Mast — Part D/Section 5A
Mast Section — Part D/Section 5A
Mast Tie — Part D/Section 5A
Mat — Part C/Section 3B
Material Efficiency — Part C/Section 6A
Maximum Thickness — Part C/Section 8
Mean Ground Level — Part C/Section 1
Mean Outer Diameter — Part C/Section 3B
Mean Radiant Temperature — Part D/Section 3
Mean Wall Thickness — Part C/Section 3B
Means of Egress — Part F
Means of Escape — Part F
Mechanical Ventilation — Part D/Section 1
Mechanically Laminated — Part C/Section 3A
Mercantile Buildings — Part C/Section 1
Meridian — Part D/Section 1
Meshed Bonding Network (*MESH-BN*) — Part D/Section 2
Metropolitan Area Network (*MAN*) — Part D/Section 6
Mill Tolerance — Part C/Section 6A
Miniature Circuit Breaker (*MCB*) — Part D/Section 2
Minimum Breaking Load — Part D/Section 5A
Minimum Thickness — Part C/Section 8
Mixed Mode Building — Part D/Section 3
Mixed Occupancy — Part F
Mixed Building or Hybrid Building — Part C/ Section 5
Mobile Equipment — Part D/Section 2
Modular Coordination — Part C/Section 7
Modular Grid — Part C/Section 7
Module — Part C/Section 7
Modulus of Elasticity (*Young*'s *Modulus*) — Part C/Section 8
Moment Frame System — Part C/Section 5
Moment Frame-Structural Wall System — Part C/Section 5
Monitoring — Part D/Section 2
Monolithic Glass — Part C/Section 8
Mortise and Tenon — Part C/Section 3B
Mould — Part C/Section 3A
Moulded Case Circuit Breaker (*MCCB*) — Part D/ Section 2
Moving Walk — Part D/Section 5B
Mullion — Part C/Section 8
Multichannel Multipoint Distribution System (*MMDS*) — Part D/Section 6
Multimodule — Part C/Section 7
Multiple-Tube System — Part C/Section 5
Multi-Tower Structures Linked by Podium — Part C/Section 5
Multiple Earthed Neutral System — Part D/Section 2
Multiple Occupancy — Part F
Multi-User Telecommunications Outlet Assembly (*MUTOA*) — Part D/Section 6
Municipal Authority — Part E/Section 3
Municipal Solid Waste — Part E/Section 3

N

Natural Ventilation — Part D/Section 1
Natural Period — Part C/Section 5

Naturally Conditioned Building — Part D/Section 3

Negative Skin Friction — Part C/Section 2

Net Section — Part C/Section 3B

Neutral Conductor — Part D/Section 2

Newel — Part D/Section 5B

Node — Part C/Section 3B

Noise — Part D/Section 4

Noise Exposure Forecast (*NEF*) — Part D/Section 4

Noise Criteria — Part D/Section 4

Noise Rating (NR) — Part D/Section 4

Noise Reduction Co-efficient (*NRC*) — Part D/Section 4

Nominal Speed — Part D/Section 5B

Nominal Thickness — Part C/Section 8

Nominal Travel Time/Theoretical Time of Travel — Part D/Section 5A

Non-Combustible Material — Part C/Section 8

Non-Return Valve — Part D/Section 5A

Non-Selective Collective Automatic Operation — Part D/Section 5A

Non-transit Occupancy — Part F

Normal Operation — Part D/Section 5A

Normal Stress — Part C/Section 6A

Normalized Impact Sound Pressure Level — Part D/Section 4

North and South Points — Part D/Section 1

Notice of Completion — Part A

O

Occupancy or Use Group — Part A, Part F, Part C/Section 1

Occupant Load — Part F

Occupant Load Factor (*OLF*) — Part F

Occupier — Part A

Occupational Exposure Limit (*OEL*) — Part D/Section 3

Octave Band — Part D/Section 4

Offset — Part C/Section 2, Part E/Section 1, Part E/Section 2

Oil Buffer Stroke — Part D/Section 5A

One Pipe-Partially Ventilated System — Part E/Section 2

One Pipe-Fully Ventilated System — Part E/Section 2

One-Way Restrictor — Part D/Section 5A

Open time — Part C/Section 7

Open Station — Part F

Operating Device — Part D/Section 5A

Operation — Part D/Section 5A

*Operational Construction/Installati*on — Part A

Operational or Services Brake — Part D/Section 5B

Operating Panel — Part D/Section 5C

Operative Temperature — Part D/Section 3

Operator of a Facility — Part E/Section 3

Optical Distribution Frame — Part D/Section 6

Optical Fibre — Part D/Section 6

Ordinary moment resisting frame (*OMRF*) — Part C/Section 1

Orientation of Buildings — Part D/Section 1

Organic Coated Glass — Part C/Section 8

Origin of an Electrical Installation — Part D/ Section 2

Outdoor Artificial Lighting — Part D/Section 1

Outer Diameter — Part C/Section 3B

Out-of-Plane Deformation — Part C/Section 7

Outgoing Traffic — Part D/Section 5A

Outside Location – Part C/Section 3A, Part C/Section 3B

Outside Plant (OSP) — Part D/Section 6

Overcurrent — Part D/Section 2

Overload Current (*of a Circuit*) — Part D/Section 2

Over Speed Governor — Part D/Section 5A

Overhead Beams — Part D/Section 5A

Owner of the Installation — Part D/Section 5A and 5B

Ozone Depletion Potential (*ODP*) — Part D/Section 3

P

Pane — Part C/Section 8

Panel — Part C/Section 8

Panel Wall — Part C/Section 4

Parking Equipment Attendant — Part D/Section 5C

Parking Unit — Part D/Section 5C

Partial Safety Factor — Part C/Section 6A and 6B

Partial Safety Factor for Loads — Part C/Section 6A and 6B

Partially Separate System — Part E/Section 2

Partition — Part C/Section 8

Partly Framed or Unframed Glazing — Part C/ Section 8

Passenger — Part D/Section 5A

Passenger Arrival Rate — Part D/Section 5A

Passenger Average Waiting Time (*AWT*) — Part D/Section 5A

Passenger Lift — Part D/Section 5A

Passive Cooling — Part D/Section 3

Passive Fire Protection — Part F

Passive Heating — Part D/Section 3

Passive Solar Gain — Part C/Section 8

Patterned Glass — Part C/Section 8

Pawl Device — Part D/Section 5A

Peak Ground Acceleration — Part C/Section 1

Peak Gust — Part C/Section 1

Peak to Peak Vibration Levels — Part D/Section 5A

Peat — Part C/Section 2

Plenum — Part F

Pelletization — Part E/Section 3

Percentile Level — Part D/Section 4

Performance Based Design — Part F

Performance Time/Door-to-Door Time — Part D/Section 5A

Perimeter Fire Barrier — Part C/Section 8

Period of Structural Adequacy under Fire — Part C/Section 6A

Period of Supply — Part E/Section 1

Peripheral Field — Part D/Section 1

Permanent Load — Part C/Section 2

Permissible Stress — Part C/Section 3A, Part C/Section 3B, Part C/Section 6A

Pessral — Part D/Section 5A

PEN Conductor — Part D/Section 2

Phase Conductor — Part D/Section 2

Pier — Part C/Section 4

Pile-Enhanced Raft — Part C/Section 2

Pile Foundation — Part C/Section 2

Pile-Pile Interaction — Part C/Section 2

Pile-Raft Interaction — Part C/Section 2

Pile-Raft Coefficient or Load Sharing Ratio (α_{CPRF}) — Part C/Section 2

Pile Spacing — Part C/Section 2

Partition Wall — Part C/Section 4

Pilot — Part E/Section 4

Pink Noise — Part D/Section 4

Pipe System — Part E/Section 2

Pipe Work — Part E/Section 1

Pit — Part D/Section 5B

Pitch — Part C/Section 6A and 6B

Pitch Pocket — Part C/Section 3A

Place of Comparative Safety — Part F

Plastic Collapse — Part C/Section 6A

Plastic Design — Part C/Section 6A

Plastic Hinge — Part C/Section 6A

Plastic Moment — Part C/Section 6A

Plastic Section — Part C/Section 6A

Plenum — Part D/Section 3

Plug — Part D/Section 2

Plumbing — Part E/Section 1, Part E/Section 2

Plumbing System — Part E/Section 1, Part E/ Section 2

Pocket Type Reinforced Masonry — Part C/Section 4

Podium — Part F

Point of Safety — Part F

Point (*in Wiring*) — Part D/Section 2

Poisson's Ratio — Part C/Section 6A

Pool — Part E/Section 1

Pool Depth — Part E/Section 1

Population — Part D/Section 5A

Portable Equipment — Part D/Section 2

Position and/or Direction Indicator — Part D/ Section 5A

Positive Drive Lift — Part D/Section 5A

Positive Ventilation — Part D/Section 1, Part D/Section 3

Potable Water — Part E/Section 1

Precast Concrete Piles in Prebored Holes — Part C/ Section 2

Precast Driven Pile — Part C/Section 2

Printable Concrete — Part C/Section 7

Prefabricate — Part C/Section 7

Prefabricated Building — Part C/Section 7

Preliminary Operation — Part D/Section 5A

Preloading — Part C/Section 2

Premises — Part E/Section 1, Part E/Section 2

Pressure Coefficient — Part C/Section 1

Pressure Balancing Valve — Part E/Section 1

Pressure Regulator — Part E/Section 4

Pressure Relief Valve — Part D/Section 5A

Pressurization — Part F

Pressurization Level — Part F

Pressurization System — Part F

Principal Rafter — Part C/Section 3B

Principal Occupancy or Use Group — Part F

Printability — Part C/Section 7

Print Plane — Part C/Section 7

Prism — Part C/Section 4

Processing — Part E/Section 3

Programmable Electronic System in Safety Related Applications for Lifts (*PESSRAL*) — Part D/Section 5A

Progressive Safety Gear — Part D/Section 5A

Progressive Horizontal Evacuation — Part F

Proof Checking/Peer Reviewing — Part A

Proof Stress — Part C/Section 6A

Proof Testing — Part C/Section 6A

Propagation Delay — Part D/Section 6

Propeller Fan — Part D/Section 1

Prospective Fault Current (I_{pf}) — Part D/Section 2

Protection, *Ingress* — Part D/Section 2

Protection, *Mechanical Impact* — Part D/Section 2

Protective Coating(*s*) *Faults* — Part C/Section 8

Protective Conductor — Part D/Section 2

Protective Conductor Current — Part D/Section 2

Protective Earthing — Part D/Section 2

Protective Separation — Part D/Section 2

Prototype Testing — Part C/Section 6A

Prying Force — Part C/Section 6A

Psychrometric Chart — Part D/Section 3

Public Mobile Network — Part D/Section 6

Public Use — Part D/Section 5C

Public Way — Part F

Pumpability — Part C/Section 7

Puff Ventilation — Part E/Section 2

Pure Tone — Part D/Section 4

Pulley Room — Part D/Section 5A

Pulley Space — Part D/Section 5A

Purge — Part E/Section 4

Purlins — Part C/Section 3B

Puzzle Parking System — Part D/Section 5C

Q

Qualified Installing Agency — Part E/Section 4

Quetta Bond Reinforced Masonry — Part C/Section 4

R

Rack and Pinion Lift — Part D/Section 5A

Radio Frequency — Part D/Section 6

Raft-Enhanced Pile — Part C/Section 2

Raft-Pile Interaction — Part C/Section 2

Ramp — Part F

Rated Current — Part D/Section 2

Rated Impulse Withstand Voltage Level — Part D/Section 2

Rated Load (*Lift*) — Part D/Section 5A, Part D/Section 5B

Rated Load — Part D/Section 5B

Rated Speed (*Lift*) — Part D/Section 5A

Rating Level — Part D/Section 4

Rebate — Part C/Section 8

Recirculated Air — Part D/Section 3

Recycling — Part E/Section 3, Part C/Section 6A

Reflected Glare — Part D/Section 1

Responsible Sourcing — Part C/Section 6A

Reflective Coated Glass — Part C/Section 8

Reflective Silver Coating Faults — Part C/Section 8

Refrigerant — Part D/Section 3

Refuge Area — Part F

Refuge Area, *Capacity* — Part F

Refuge Space — Part D/Section 5A, Part F

Registered Building Professional Architect, Engineer, Structural Engineer, Geotechnical Engineer, Supervisor, Town Planner, Landscape Architect, Urban Designer — Part A

Registered Building Professional — Part A

Reinforced Brick Slab (*RB Slab*) — Part C/Section 4

Reinforced Brick Concrete Slab (*RBC Slab*) — Part C/Section 4

Reinforced Masonry — Part C/Section 4

Relative Humidity — Part D/Section 3

Re-levelling — Part D/Section 5A

Relief Vent — Part E/Section 2

Reinforced Brick Slab — Part C/ Sec 4

Reinforced Brick Concrete Slab — Part C/ Sec 4
Retaining Device — Part D/Section 5A
Rescue Operations — Part D/Section 5A
Residential Buildings — Part C/Section 1
Residual Breaking Load (*RBL*) — Part D/Section 5A
Residual Current — Part D/Section 2
Residual Current Device — Part D/Section 2
Residual Current Operated Circuit Breaker — Part D/Section 2
Residual Current Operated Circuit Breaker with Integral Overcurrent Protection (*RCBO*) — Part D/Section 2
Residual Current Operated Circuit Breaker without Integral Overcurrent Protection (*RCCB*) — Part D/Section 2
Residual Head — Part E/Section 1
Residual Operating Current — Part D/Section 2
Residual Pressure — Part E/Section 1
Residual Protection — Part C/Section 8
Restricted Access — Part D/Section 5C
Restrictor — Part D/Section 5A
Retiring Cam/Coupler — Part D/Section 5A
Return Period — Part C/Section 1
Return Air — Part D/Section 3
Reuse — Part C/Section 6A
Reveal — Part D/Section 1
Reverberation Time — Part D/Section 4
Ride Quality — Part D/Section 5B
Rigid Shear Connectors — Part C/Section 6B
Rise (*Travel*) — Part D/Section 5B
Riser — Part E/Section 4
Road Traffic — Part D/Section 4
Roof Battens — Part C/Section 3B
Roof Exits — Part F
Roof Skeleton — Part C/Section 3B
Room Index — Part D/Section 1
Roping Multiple — Part D/Section 5A
Rotation — Part C/Section 6A
Round Trip Time (*RTT*) — Part D/Section 5A
Routine Test — Part C/Section 2
Round Trip Time — Part D/Section 5A
Rupture Valve — Part D/Section 5A

S

S-N Curve — Part C/Section 6A and 6B
Saddle — Part E/Section 1, Part E/Section 2
Safe Load — Part C/Section 2
Safety Circuit — Part D/Section 5B
Safety Devices — Part D/Section 5B
Safety Gear — Part D/Section 5A, Part D/Section 5A, Part D/Section 5C
Safety Glass — Part C/Section 8
Safety Component — Part D/Section 5A
Safety Circuit — Part D/Section 5A
Safety Integrity Level — Part D/Section 5A
Safety Rope — Part D/Section 5A
Safety Switch — Part D/Section 5C
Sand — Part C/Section 2
Sand, Coarse — Part C/Section 2
Sand, Fine — Part C/Section 2
Sand, Medium — Part C/Section 2
Sandwich Concrete Panels — Part C/Section 7A
Sandwich, Structural — Part C/Section 3A
Sanitary Appliances — Part E/Section 2
Sap Stain — Part C/Section 3A
Sapwood — Part C/Section 3A
Secondary Member — Part C/Section 6A
Seismic Mode — Part D/Section 5A
Seismic Stand — *By Mode* — Part D/Section 5A
Seismic Trigger Level — Part D/Section 5A
Semi-compact Section — *Part C*/Section 6A
Segregation — Part E/Section 3
Seismic Zone and Seismic Coefficient — Part C/Section 4
Selective Collective Automatic Operation — Part D/Section 5A
Self-Compacting Concrete — Part C/Section 7
Separated Occupancy — Part F
Separation Section — Part C/Section 4
Sensible Cooling — Part D/Section 3
Sensible Heat — Part D/Section 3
Separate System — Part E/Section 2
Series — Part D/Section 5C

Server — Part D/Section 6
Service — Part D/Section 2
Service Floor — Part F
Service Lift — Part D/Section 5A
Service Limit — Part C/Section 6B
Serviceability Loads — Part C/Section 6B
Service Pipe — Part E/Section 1, Part E/Section 4
Service Road/Lane — Part A
Service Shut-Off Valve (*Isolation Valve*) — Part E/Section 4
Serviceability Limit State — Part C/Section 6A
Set-Back Line — Part A
Settlement Reduction Ratio (*SRR*) — Part C/Section 2
Sewer — Part E/Section 2
Shade Factor — Part D/Section 3
Shape Stability — Part C/Section 7
Shading Coefficient — Part C/Section 8
Shake — Part C/Section 3A
Shallow Area — Part E/Section 1
Shallow Foundation — Part C/Section 2
Shear Connectors — Part C/Section 7, Part C/ Section 6 B
Shear Force — Part C/Section 6A
Shear Lag — Part C/Section 6A
Shear Stress — Part C/Section 6A
Shear Wall — Part C/Section 4
Sheave — Part D/Section 5A
Sheet Glass — Part C/Section 8
Shielding Effect — Part D/Section 2, Part C/Section 1
Shock Current — Part D/Section 2
Short-Circuit Current — Part D/Section 2
Shut-off Valve — Part D/Section 5A
Sick Building Syndrome (*SBS*) — Part D/Section 3
Signal Operation — Part D/Section 5A
Silt — Part C/Section 2
Single Automatic Operation — Part D/Section 5A
Single Acting Jack — Part D/Section 5A
Single Floor Flight Time — Part D/Section 5A
Single Floor Transit Time — Part D/Section 5A
Single Stack System — Part E/Section 2
Site (*Plot*) — Part F
Skimmer — Part E/Section 1
Skirt Deflector — Part D/Section 5B
Skirting — Part D/Section 5B
Sky Component (*SC*) — Part D/Section 1
Sky Lobby — Part D/Section 5A
Skylight — Part C/Section 8
Slack Rope Switch — Part D/Section 5A
Slender Section — Part C/Section 6A
Slenderness Ratio — Part C/Section 3B, Part C/ Section 4, Part C/Section 6A
Slip Resistance — Part C/Section 6A and 6B
Slit — Part C/Section 2
Sliver — Part C/Section 3B
Slop Hopper (*Slop Sink*) — Part E/Section 2
Slope of Grain — Part C/Section 3A
Sloped Overhead Glazing — Part C/Section 8
Small CPRF — Part C/Section 2
Smart City/Building/Home — Part D/Section 6
Smoke Barrier — Part F, Part D/Section 3
Smoke Compartment — Part F
Smoke Control — Part F
Smoke Curtain — Part F
Smoke Damper — Part D/Section 3
Smoke Management — Part D/Section 3
Smoke Vent Panel — Part F
Snag Point — Part D/Section 5A
Snow Load — Part C/Section 6A
Snug Tight — Part C/Section 6A and 6B
Soakaway — Part E/Section 2
Socket-Outlet — Part D/Section 2
Softening Behaviour – Part C/Section 5
Soffit (*Crown*) — Part E/Section 2
Soft Rock — Part C/Section 2
Soft Storey — Part C/Section 1
Soil Appliances — Part E/Section 2
Soil Densification — Part C/Section 2
Soil Pipe — Part E/Section 2
*Soil Reinforc*ement — Part C/Section 2
Soil Waste — Part E/Section 2
Soil, Black Cotton — Part C/Section 2
Soil, Coarse Grained — Part C/Section 2
Soil, Fine Grained — Part C/Section 2
Soil, Highly Organic and Other Miscellaneous Soil Materials — Part C/Section 2
Solar Energy Absorption — Part C/Section 8

Solar Energy Transmittance (*Direct*) — Part C/ Section 8
Solar Heat Gain Coefficient (*SHGC*) — Part C/Section 8
Solar Load — Part D/Section 1
S-N curve — Part C/Section 6A
Solid-State d.c. Variable Voltage Control — Part D/Section 5A
Solidity Ratio — Part C/Section 1
Sound — Part D/Section 4, Part D/Section 5A
Sound Exposure Level — Part D/Section 4
Sound Knot — Part C/Section 3A
Sound Level Difference — Part D/Section 4
Sound Power — Part D/Section 4
Sound Power Level — Part D/Section 4
Sound Pressure Level, Lw – Part D/Section 4
Sound Pressure Level, L_p — Part D/Section 4, Part D/Section 5B
Sound Pressure Level, $L_{p,A}$ — Part D/Section 5A
Sound Pressure, p — Part D/Section 4
Sound Receiver — Part D/Section 4
Sound Reduction Index, R — Part D/Section 4
Sound Source — Part D/Section 4
Space Factor — Part D/Section 2
Spaced Column — Part C/Section 3A
Spandrel — Part C/Section 8
Specified Compressive Strength of Masonry — Part C/ Section 4
Spectrum — Part D/Section 4
Special Tool — Part D/Section 5A
Speech Interference Level (*SIL*) — Part D/Section 4
Splicing — Part D/Section 6
Split — Part C/Section 3A
Splits — Part C/Section 3B
Spot Faults — Part C/Section 8
Spray-Head System — Part D/Section 1
Spread (*or Isolated or Pad*) *Foundation/Footing* — Part C/Section 2
Spring Buffer Load Rating — Part D/Section 5A
Speed of Extrusion (*Extrusion Speed*) — Part C/ Section 7
Spring Buffer Stroke — Part D/Section 5A
Stability, Limit State — Part C/Section 6A and 6B
Stack Effect — Part D/Section 1, Part D/Section 3
Stack Pressure — Part F
Stack Vent — Part E/Section 2
Staging Area — Part F
Stain — Part C/Section 8
Standardized Impact Sound Pressure Level — Part D/ Section 4
Standby Supply System — Part D/Section 2
Stack Parking System — Part D/Section 5C
Standardized Level Difference — Part D/Section 4
Start Delay Time — Part D/Section 5A
Static Pressure — Part D/Section 3, Part E/Section 1
Station — Part F
Stationary Equipment — Part D/Section 2
Station Platform — Part F
Steel Fibre Reinforced Concrete (*SPRC*) — Part C/ Section 5
Step Voltage — Part D/Section 2
Stickability — Part C/Section 6A
Stiffener — Part C/Section 6A, Part C/Section 6B
*Stock/Standard Size*s — Part C/Section 8
Stop Tap — Part E/Section 1
Stop-Cock — Part E/Section 1
Stopping Accuracy — Part D/Section 5A
Storage — Part E/Section 3
Storage Buildings — Part C/Section 1
Storage Tank — Part E/Section 1
Street — Part A
Street Level or Grade — Part A
Street Line — Part A
Strain — Part C/Section 6A
Strain Hardening — Part C/Section 6A
Strength — Part C/Section 6A
Strength Factors — Part C/Section 6 B
Strength Limit State — Part C/Section
Stress — Part C/Section 6A
Stress Analysis — Part C/Section 6A, Part C/ Section 6B
Stress Cycle Counting — Part C/Section 6A
Stress Range — Part C/Section 6A, Part C/Section 6B
Stress Spectrum — Part C/Section 6A
Stressed Skin — Part C/Section 3A
Strip Foundation/Footing — Part C/Section 2
Structural Adequacy for Fire — Part C/Section 6A

Structural Analysis — Part C/Section 6A, Part C/Section 6B

Structural Wall System — Part C/Section 5

Structural Element — Part C/Section 3A

Structural Grades — Part C/Section 3A

Structural Wall System with Flat Slab Floor System — Part C/Section 5

Structural Timber — Part C/Section 3A

Structure Borne Noise — Part D/Section 4

Structure Borne Noise and *Ground Noise* — Part D/Section 4

Structure, Permanent — Part C/Section 3A

Structure, Temporary — Part C/Section 3A

Strut — Part C/Section 6A

Stud — Part C/Section 3A

Studio Apartment — Part E/Section 1

Subsoil Water — Part E/Section 1, Part E/Section 2

Subsoil Water Drain — Part E/Section 1, Part E/Section 2

Substation — Part D/Section 2

Sub-zero Temperature Regions — Part E/Section 1

Suction — Part C/Section 1

Sullage — Part E/Section 2

Superimposed Dead Load — Part C/Section 6B

Supply Air — Part D/Section 3

Supply Pipe — Part E/Section 1, Part E/Section 2

Supports — Part E/Section 1, Part E/Section 2

Super Tall Building — Part C/Section 5

Surface Cracking — Part C/Section 3B

Surface Reflectance — Part D/Section 1

Surface Water — Part E/Section 1, Part E/Section 2

Surface Water Drain — Part E/Section 1, Part E/Section 2

Surge — Part D/Section 2

Surge Protective Devices — Part D/Section 2

Suspension Means — Part D/Section 5A

Suspension Member — Part D/Section 5A

Suspension Ropes — Part D/Section 5A

Sustainability — Part D/Section 2

Sustainable Development — Part C/Section 6A

Sway — Part C/Section 6A

Sway Member — Part C/Section 6A

Swimming Pool User Load — Part E/Section 1

Switch Disconnector — Part D/Section 2

Switch Disconnector Fuse — Part D/Section 2

Switch — Part D/Section 2

Switch, Linked — Part D/Section 2

Switchboard — Part D/Section 2

Switchgear — Part D/Section 2

System — Part C/Section 7

Systems, Earthing — Part D/Section 2

System (Electrical) — Part D/Section 2

Systems of Drainage — Part E/Section 2

T

Taper — Part C/Section 3B

Target Dosage – Part C/Section 5

Tall Building — Part C/Section 1, Part C/Section 5

Telecommunication Spaces — Part D/Section 6

Telecom Service Provider (*TSP*) — Part D/Section 6

TelecomTower/Mast/Pole — Part D/Section 6

Telecommunication Media and Connecting Hardware — Part D/Section 6

Tensile Stress — Part C/Section 6A, Part C/Section 6B

Tempered Fire Resistant Glass — Part C/Section 8

Terminal Devices — Part D/Section 3

Terminal Slow Down Switch — Part D/Section 5A

Terminal Stopping Device Final — Part D/Section 5A

Terminal Stopping Switch Normal — Part D/Section 5A

Termite — Part C/Section 3A

Terrain Category — Part C/Section 1

Test Assembly — Part C/Section 8

Test Load — Part C/Section 6A, Part C/Section 6B

Thermal Adaptation — Part D/Section 3

Thermal Comfort — Part D/Section 3

Thermal Energy Storage — Part D/Section 3

Thermal Insulation Material — Part D/Section 3

Thermal Runaway — Part D/Section 2

Thermal Transmittance, U-Value — Part C/Section 8

Thermostatic/Pressure Balancing Valve — Part E/Section 1

Third Octave Band — Part D/Section 4

Threshold Limit Value (*TLV*) — Part D/Section 1

Threshold of Hearing — Part D/Section 4
Through Component/Connection — Part C/Section 8
Tight Knot — Part C/Section 3A
Tinted Glass — Part C/Section 8
Tissue — Part C/Section 3B
TN System — Part D/Section 2
TN-C System — Part D/Section 2
TN-S System — Part D/Section 2
TN-C-S System — Part D/Section 2
TT System — Part D/Section 2
IT System — Part D/Section 2
Top Car Clearance — Part D/Section 5A
Top Counterweight Clearance — Part D/Section 5A
Top Refuge Space — Part D/Section 5A
Topography — Part C/Section 1
Total Settlement — Part C/Section 2
Touch Voltage — Part D/Section 2
Toughened (*Tempered*) *Safety Glass* — Part C/Section 8
Toxic Gases — Part F
Trade Effluent — Part E/Section 2
Transfer Area — Part D/Section 5C
Transfer Structure — Part C/Section 5
Transient Sound — Part D/Section 4
Transient Load — Part C/Section 6 B
Transient Sleeping Accommodation — Part F
Transit Time — Part D/Section 5A
Transition Point — Part E/Section 1
Transom — Part C/Section 8
Transportation — Part E/Section 3
Traceability — Part C/Section 6A
Transverse — Part C/Section 6A
Traction Lift — Part D/Section 5A
Trap — Part E/Section 2
Travel — Part D/Section 5A
Travelling Cable — Part D/Section 5A
Travel Distance — Part F
Tropical Summer Index (*TSI*) — Part D/Section 1
Tube-in-Tube System — Part C/Section 5
Turnover Period — Part E/Section 1
Two Pipe System — Part E/Section 2
Two Pipe System with Common Vent Pipes — Part E/Section 2
Two Pipe System with Independent Vent Pipes — Part E/Section 2
Type of Construction — *Part F*
Types of Walls — Part C/Section 4

U

Ultimate Load Capacity — Part C/Section 2
Ultimate Limit State — Part C/Section 6A, Part C/Section 6B
Ultimate Stress — Part C/Section 6A
Underground Cable Vault (*UCV*) — Part D/Section 6
Under-Reamed Pile — Part C/Section 2
Unframed Glazing — Part C/Section 8
Unintended Car Movement — Part D/Section 5A
Unit — Part C/Section 7
Unloaded End Distance — Part C/Section 3B
Unlocking Zone — Part D/Section 5A
Unsafe Building — Part A
Usable Wall Space — Part D/Section 2
Untenable Conditions — Part F
User — Part D/Section 5A
Utility Building — Part D/Section 2
Utilization Factor (*Coefficient of Utilization*) (μ) — Part D/Section 1
UV Transmittance — Part C/Section 8
UV A — Part D/Section 1
UV B — Part D/Section 1

V

V95 — Part D/Section 5A
Variable Refrigerant Flow (*VRF*) *System* — Part D/Section 3
Variable Voltage Motor Control (*Generator Field Control*) — Part D/Section 5A
Vacuum Breaker — Part E/Section 1
Velocity — Part D/Section 5A, Part D/Section 5B
Velocity, Capture — Part D/Section 1
Velocity Pressure — Part D/Section 3
Velocity Profile — Part C/Section 1
Veneered Wall — Part C/Section 4
Vent Pipe — Part E/Section 4

Vent Stack/Vent Pipe — Part E/Section 2

Vent System — Part E/Section 2

Ventilation — Part F, Part D/Section 1

Venting Fire — Part F

Vermi-composting — Part E/Section 3

Vertical Fenestration — Part C/Section 8

Vertical Movements — Part D/Section 5C

Vertical Pipe — Part E/Section 1, Part E/Section 2

Very Small Aperture Terminal — Part D/Section 6

Vibration — Part D/Section 5A, Part D/Section 5B

Vibration Isolation — Part D/Section 4

Visibility — Part F

Viscosity Modifier — Part C/Section 7

Visual Field — Part D/Section 1

Visual Strobes/Flashing — Part F

Voltage, Extra Low (*ELV*) — Part D/Section 2

Voltage, Extra High (*EHV*) — Part D/Section 2

Voltage, High (*HV*) — Part D/Section 2

Voltage, Low (*LV*) — Part D/Section 2

Voltage, Nominal (*of an Installation*) — Part D/Section 2

Volume to Plot Area Ratio (*VPR*) — Part F

W

Wading Pool — Part E/Section 1

Wall Thickness — Part C/Section 3B

Wall Tie — Part C/Section 4

Wane — Part C/Section 3A

Warning Pipe — Part E/Section 1

Warp — Part C/Section 3A

Wash-Out Valve — Part E/Section 1

Waste Appliance — Part E/Section 2

Waste Pipe — Part E/Section 2

Waste-Water (*Sullage*) — Part E/Section 2

Water Based Systems — Part F

Water Closet — Part E/Section 2

Water Curtain — Part F

Water Hammer Arrestor — Part E/Section 1

Water Hardness — Part D/Section 3

Water Level — Part E/Section 1

Water Main (*Street Main*) — Part E/Section 1

Water Mist Systems — Part F

Water Outlet — Part E/Section 1

Water Seal — Part E/Section 2

Water Supply System — Part E/Section 1

Water Treatment — Part D/Section 3

Waterworks — Part E/Section 1

Wavelength — Part D/Section 4

Weatherproof — Part D/Section 2

Weighted Level Difference, D_{w} — Part D/Section 4

Weighted Normalized Impact Sound Pressure Level, $L'_{\mathrm{n.w}}$ — Part D/Section 4

Weighted Sound Reduction Index, R_{w} — Part D/Section 4

Weighted Standardized Impact Sound Pressure Level, $L'_{\mathrm{nT,w}}$ — Part D/Section 4

Weighted Standardized Level Difference, $D_{n,\mathrm{Tw}}$ — Part D/Section 4

Wet Bulb Temperature — Part D/Section 1, Part D/Section 3

Wet Location — Part C/Section 3A, Part C/Section 3B

Wet Riser — Part F

Wheel Base — Part D/Section 5C

Wheel Track Width — Part D/Section 5C

White Noise — Part D/Section 4

Wholesome Water — Part E/Section 1

Wide Area Network (*WAN*) — Part D/Section 6

Wind Loads — Part C/Section 6A

Wired Glass — Part C/Section 8

Working Area — Part D/Section 5A, Part D/Section 5C

Working Load — Part C/Section 2

Working Pile — Part C/Section 2

Working Plane — Part D/Section 1

Workstation — Part D/Section 6

Workspace — Part D/Section 6

Worm Holes — Part C/Section 3A

Wrinkled and Deformed Surface — Part C/Section 3B

Y

Yield Stress — Part C/Section 6A, Part C/Section 6B

Yoke Vent — Part E/Section 2

Z

Zero-Depth Edge — Part E/Section 1

Zero-Depth Pool — Part E/Section 1

FOREWORD

This NBCS (Part D/Section 1) covers the lighting and natural ventilation requirements in buildings. Thermal comfort conditions for the building occupants and illumination levels for different tasks are recommended to be achieved either by daylighting or artificial lighting or a combination of both. This section, read together with Part D 'Building Services, Section 2 Electrical and Allied Installations' of this NBCS, adequately covers the thermal comfort conditions for naturally ventilated buildings and mixed mode operation buildings, and the illumination levels required and methods of achieving the same.

Ventilation requirements to maintain air quality, control body odours and pollutants in terms of air changes per hour and to ensure thermal comfort and heat balance of body are laid for different occupancies and the methods of achieving the same by natural means or mixed mode operations means are covered in this Section. The provisions on mechanical ventilation are covered in Part D 'Building Services, Section 3 Air Conditioning, Heating and Mechanical Ventilation' of this NBCS.

Climatic factors which normally help in deciding the orientation of the buildings to get desirable benefits of lighting and natural ventilation inside the buildings are also covered in this section.

This section was first published in 1970 as a part of National Building Code of India. The first revision of the section was brought out in 1983. In the second revision of 2005, some provisions were updated based on the information given in the SP 41 : 1987 'Handbook on functional requirements of buildings (other than industrial buildings)'; other major changes in the 2005 revision included rationalization of definitions and inclusion of definitions for some more terms; inclusion of climatic classification map of India based on a new criteria; updating of data on total solar radiations incident on various surfaces of buildings for summer and winter seasons; inclusion of design guidelines for natural ventilation; reference to Part 8 'Building Services, Section 3 Air Conditioning, Heating and Mechanical Ventilation' of the Code for guidelines on mechanical ventilation, made, where these provisions were covered exhaustively; inclusion of rationalized method for estimation of desired capacity of ceiling fans and their optimum height above the floor for rooms of different sizes; incorporation of design sky illuminance values for different climatic zones of India, etc. Energy efficiency was another important aspect which was considered. Accordingly, the relevant requirements for energy efficient system for lighting and natural ventilation were duly included in the concerned provisions under the section.

In third revision of the Code in 2016, the changes that were incorporated include; elaboration of the calculation for solar load, and inclusion of 'Method of calculating solar load on vertical surfaces in different orientation' in Annex A; inclusion of provisions on sky component calculation procedure along with examples in Annex B; inclusion of reference to SP 41 : 1987 for obtaining coefficient utilization for determination of luminous flux; updation of provisions relating to efficient artificial light source and luminaires; inclusion of modern lighting techniques such as LED and induction light in comparison with their energy consumption; updation of provisions relating to photocontrols for artificial lights; inclusion of definitions and enabling provision for lighting shelves and light pipes; elaboration of the provisions related to thermal comfort including indices such as effective temperature, adaptive thermal comfort along with elaborations on tropical summer index; elaboration of design guidelines for natural ventilation with illustrations; elaboration of provisions related to determination of rate of ventilation particularly on combined effect of wind and thermal actions; and inclusion of provision on colour rendering in line with that in SP 72 : 2010 'National Lighting Code 2010'.

In this revision, this publication has been renamed as National Building Construction Standards (NBCS).

As a result of experience gained since the implementation of the 2016 version of this NBCS and feedback received as well as revisions of Indian Standards on which this Section was based, a need was felt to revise this Section. The significant changes incorporated in this revision include the following:

a) Terminology clause has been updated with new terms and definitions;

b) Orientation of building clause has been renamed to site planning and building placement; and

c) The clause on aspects of daylighting has been updated;

d) Provisions for spatial and environmental consideration in building design; and operable windows and UV exposure have been added;

e) The aims of good lighting clause has been updated;

f) Table 6 for illuminance and lighting performance parameters have been updated;

g) Provisions for planning and design guidelines for circadian lighting including supplementary artificial circadian lighting have been introduced;

h) Planning and design guidelines for outdoor lighting and its energy efficiency aspects have been introduced;

j) Detailed provisions on design charts for natural ventilation and acceptable air temperature with the increase in the air speed have been added;

k) Provisions of the adaptive thermal comfort mode of ventilation have been reviewed and updated;

The provisions of this Section are without prejudice to the various acts, Rules and Regulations including the *Factories Act*, 1948 and Rules and Regulations framed thereunder.

The information contained in this Section is largely based on the following Indian Standards/Special Publications:

IS 2440 : 1975	Guide for daylighting of buildings (*second revision*)
IS 3103 : 1975	Code of practice for industrial ventilation (*first revision*)
IS 3362 : 1977	Code of practice for natural ventilation of residential buildings (*first revision*)
IS 3646 (Part 1) : 2025	Interior illumination — Code of practice: Part 1 General requirements and recommendations for working interiors (*second revision*)
IS 7662 (Part 1) : 1974	Recommendations for orientation of buildings: Part 1 Nonindustrial buildings
IS 11907 : 1986	Recommendations for calculation of solar radiation on buildings
SP 32 : 1986	Handbook on functional requirements of industrial buildings (lighting and ventilation)
SP 41 : 1987	Handbook on functional requirements of buildings other than industrial buildings

Provisions given in National Lighting Code of India, 'SP 72 : 2025' (*first revision*) may also be referred.

All standards, whether given herein above or cross-referred to in the main text of this Section, are subject to revision. The parties to agreement based on this Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

Assistance has been taken from the following documents in the revision of this Section:

'Report on Energy Conservation in Buildings', submitted to Department of Power, Ministry of Energy by CSIR-Central Building Research Institute, Roorkee.

'Adaptive thermal comfort model based on fields studies in five climate zones across India', Building and Environment, Volume 219, 1 July 2022 by Rawal, R., Shukla, Y., Vardhan, V., et al. (2022)

'Field studies of thermal comfort across multiple climate zones for the subcontinent: India Model for Adaptive Comfort (IMAC)', *Building and Environment*, 98 (March 2106), (pp. 55–70) by Manu, S., Shukla, Y., Rawal, R., Thomas, L. E., and De Dear, R. (2016)

'Low Energy Cooling and Ventilation for Indian Residences: Design Guide', Loughborough University, UK and CEPT Research and Development Foundation (CRDF), India by Cook, M., Shukla, Y., Rawal, R., Loveday, D., Faria, L. C., and Angelopoulos, C. (2020).

As the regulation of land development and buildings is a State subject and is dealt by the States and local bodies such as urban local bodies within their jurisdiction through building regulatory documents like building regulations, building byelaws, and fire regulations, this document is voluntary in nature and is non-binding. The implementation depends on adoption by concerned parties or stipulations in a contract or by appropriate adoption by the concerned authorities.

For the purpose of deciding whether a particular requirement of this Section is complied with, the final value, observed or calculated, expressing the result of a test or analysis, shall be rounded off in accordance with IS 2 : 2022 ‘Rules for rounding off numerical values (*second revision*)’. The number of significant places retained in the rounded off value should be the same as that of the specified value in this Section.

Important Explanatory Note for Users of this NBCS

In any Part/Section of this NBCS, where reference is made to **'good practice'** in relation to design, constructional procedures or other related information, and where reference is made to **"accepted standard"** in relation to material specification, testing, or other related information, the Indian Standards listed at the end of the Part/Section shall be used as a guide to the interpretation.

At the time of publication, the editions indicated in the standards were valid. All standards are subject to revision and parties to agreements based on any Part/ Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

In the list of standards given at the end of a Part/Section, the number appearing within parentheses in the first column indicates the number of the reference of the standard in the Part/Section. For example:

a) Good practices [D-1(1)] refers to the Indian Standard(s) give at serial number (1) of the list of standards given at the end of this Part D/Section 1, that is, IS 7662 (Part 1) : 1974 'Recommendations for orientation of buildings: Part 1 Non-industrial buildings'

NATIONAL BUILDING CONSTRUCTION STANDARDS

PART D BUILDING SERVICES

SECTION 1 LIGHTING AND NATURAL VENTILATION

1 SCOPE

1.1 This NBCS (Part D/Section 1) covers requirements and methods for lighting and natural ventilation of buildings.

1.2 For all buildings and facilities open to and used by the public, including all forms of public housing by the government/civic bodies and private developers, adequate lighting and natural ventilation for barrier-free access and movement within and around buildings by elderly and persons with disabilities and of different age groups shall be ensured. The ventilation through the building envelope elements such as windows, skylights, ventilators for thermal comfort and better air quality requirements are included in this section.

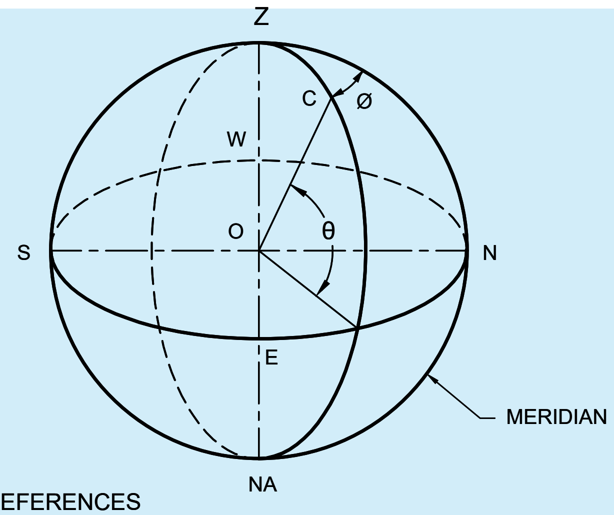
2 TERMINOLOGY

For the purpose of this Section, the following definitions shall apply.

2.1 Lighting

2.1.1 *Altitude* (θ) — The angular distance of any point of celestial sphere, measured from the horizon, on the great circle passing through the body and the zenith (*see* Fig. 1).

2.1.2 *Azimuth* (Φ) — The angle measured between meridians passing through the north point and the point in question (point C in Fig. 1).



REFERENCES

O - Observer's station

C - Celestial body

Z - Zenith

NA - Nadir

S - Geographical south

E - Geographical east

W - Geographical west

N - Geographical north

FIG. 1 ALTITUDE AND AZIMUTH OF A CELESTIAL BODY

2.1.3 *Brightness Ratio or Contrast* — The variations or contrast in brightness of the details of a visual task, such as white print on blackboard.

2.1.4 *Candela* (*cd*) — The SI unit of luminous intensity.

Candela = 1 lumen per steradian

2.1.5 *Central Field* — The area of circle around the point of fixation and its diameter, subtending an angle of about 2 degrees at the eye. Objects within this area are most critically seen in both their details and colour.

2.1.6 *Clear Design Sky* — The distribution of luminance of such a sky is non-uniform; the horizon can be brighter than the zenith depending on the sun position, and when L_z is the brightness at zenith, the brightness at an altitude (θ) in the region away from the sun, is given by the expression:

$$L_\theta = L_z \operatorname{cosec} \theta \ (\text{for } 15^\circ < \theta \leq 90^\circ)$$

$$L_\theta = L_z \operatorname{cosec} 15^\circ \ (\text{for } 0^\circ \leq \theta \leq 15^\circ) = 3.863\ 7\ L_z$$

2.1.7 *Circadian Lighting* — A lighting means that uses electric lights in a way that supports natural sleep and wake cycle of humans. This is done by changing how bright the light is and what colour it is throughout the day, so it matches what the body expects from natural daylight and night time.

2.1.8 *Colour Rendering Index* (*CRI*) — Measure of the degree to which the psychophysical colour of an object illuminated by the test illuminant conforms to that of the same object illuminated by the reference illuminant, suitable allowance having been made for the state of chromatic adaptation.

2.1.9 *Correlated Colour Temperature* (*CCT*) (*K*) — The temperature of the Planckian radiator whose perceived colour most closely resembles that of a given stimulus at the same brightness and under specified viewing conditions.

2.1.10 *Daylighting* — The strategic use of natural optical radiation from the sun and sky to illuminate interior spaces, enhancing visual comfort and supporting human circadian regulation. In this context, daylight encompasses the portion of solar radiation within the visible spectrum, typically between 380 nm and 780 nm. Effective daylighting design aims to maximize natural light penetration, minimize reliance on electric lighting, and promote occupant health and well-being.

2.1.11 *Daylight Area* — The portion of an interior space where the working plane receives natural light at or above a specified daylight factor or meets a defined minimum illuminance threshold. This area is typically delineated by a daylight factor contour, representing zones with adequate daylight levels for visual tasks.

2.1.12 *Daylight Factor* — The ratio, expressed as a percentage, of the illuminance at a specific point on a given plane indoors to the simultaneous illuminance on a horizontal plane outdoors under an overcast sky. This factor measures the amount of daylight reaching the indoor point relative to outdoor conditions, providing an indication of natural light availability in interior spaces.

2.1.13 *Daylight Penetration* — The maximum distance to which a given daylight factor contour penetrates into a room.

2.1.14 *Direct Solar Illuminance* — The illuminance from the sun without taking into account the light from the sky.

2.1.15 *External Reflected Component* (*ERC*) — Daylight illuminance at a point which is received by direct reflection from external surfaces.

2.1.16 *Glare* — A condition of vision in which there is discomfort or a reduction in the ability to see significant objects or both due to an unsuitable distribution or range of luminance or due to extreme contrasts in space.

2.1.17 *Illuminance* — At a point on a surface, the ratio of the luminous flux incident on an infinitesimal element of the surface containing the point under consideration to the area of the element.

NOTE — The unit of illuminance (the measurement of illumination) is lux which is 1 lumen per m^2.

2.1.18 *Indoor Artificial Lighting* — Artificial lighting powered by electricity, designed to enhance visual comfort, task performance, and occupant well-being in indoor environments. Its effectiveness is assessed using several key parameters:

a) *Spectral power density* (*SPD*) — Describes the relative power of a light source at each wavelength across the visible spectrum. SPD influences colour rendering, visual perception and biological effects, including circadian response;

b) *Colour tuning* — The capability to dynamically adjust the correlated colour temperature (*CCT*) and spectral content of the light source, allowing adaptation to user preferences, visual tasks, or time-of-day considerations to support circadian health;

c) *Light flicker* — Rapid fluctuations in luminous intensity that may be visible or invisible to the human eye. Flicker can cause visual fatigue, headaches, or reduced task performance. The P_{st}^{LM} value (short-term flicker severity measured by the light flickermeter method) is used to quantify flicker in lighting systems; and

d) *Unified glare rating* (*UGR*) — A standardized metric that quantifies discomfort glare in indoor spaces. Lower UGR values indicate better visual comfort and help prevent visual strain without reducing task visibility.

2.1.19 *Internal Reflected Component* (*IRC*) — Daylight illuminance at a point in a given plane which is received by direct reflection or inter-reflection from the internal surfaces.

2.1.20 *Light Output Ratio* (*LOR*) *or Efficiency* (η) — The ratio of the luminous flux emitted from the luminaire to that emitted from the lamp(s) (nominal luminous flux). It is expressed in percent.

2.1.21 *Light Pipe* — A conduit made of a highly reflective material, which is capable of channelling light from one end to the other through successive internal reflections. Such a pipe may be flexible or rigid.

2.1.22 *Light Shelf* — A daylighting system based on sun path geometry used to bounce the light off a ceiling, project it deeper into a space, distribute it from above and diffuse it to produce a uniform light level below.

2.1.23 *Lumen* (*lm*) — SI unit of luminous flux. The luminous flux emitted within unit solid angle (one steradian) by a point source having a uniform intensity of one candela.

2.1.24 *Luminance* (*at a Point of a Surface in a Given Direction*) (*Brightness*) — The quotient of the luminous intensity in the given direction of an infinitesimal element of the surface containing the point under consideration by the orthogonally projected area of the element on a plane perpendicular to the given direction. The unit is candela per square metre (cd/m^2).

2.1.25 *Luminous Flux* (ϕ) — The quantity characteristic of radiant flux which expresses its capacity to produce visual sensation evaluated according to the values of relative luminous efficiency for the light adapted eye:

a) *Effective luminous flux* (ϕ_n) — Total luminous flux which reaches the working plane; and

b) *Nominal luminous flux* (ϕ_o) — Total luminous flux of the light sources in the interior.

2.1.26 *Maintenance Factor* (*d*) — The ratio of the average illuminance on the working plane after a certain period of use of a lighting installation to the average illuminance obtained under the same conditions for a new installation.

2.1.27 *Meridian* — It is the great circle passing through the zenith and nadir for a given point of observation.

2.1.28 *North and South Points* — The point in the respective directions where the meridian cuts the horizon.

2.1.29 *Orientation of Buildings* — In the case of non-square buildings, orientation refers to the direction of the normal to the long axis. For example, if the length of the building is east-west, its orientation is north-south.

2.1.30 *Outdoor Artificial Lighting* — Lighting systems specifically designed for exterior environments, intended to enhance visibility, safety and security during nighttime hours while minimizing adverse environmental and ecological impacts. Key considerations include:

a) *Fully shielded* — Luminaire designs that emit light only in the downward direction, preventing upward light emissions. This helps control glare and limits contributions to light pollution;

b) *Full cut-off* — A luminaire classification where zero light is emitted at or above the horizontal plane of the fixture. This design minimizes sky glow and enhances lighting efficiency by directing light only where it is needed;

c) *Light trespass* — The unintended or intrusive illumination of areas beyond the target zone, such as neighbouring properties, streets, or natural habitats. Light trespass can lead to discomfort, sleep disruption and privacy issues; and

d) *Sky glow* — The diffuse illumination of the night sky caused by artificial lighting, particularly from urban areas. Sky glow reduces the visibility of stars, interferes with astronomical observations and disrupts nocturnal ecosystems.

2.1.31 *Peripheral Field* — It is the rest of the visual field which enables the observer to be aware of the spatial framework surrounding the object seen.

NOTE — A central part of the peripheral field, subtending an angle of about 30º on either side of the point of fixation, is chiefly involved in the perception of glare.

2.1.32 *Reflected Glare* — The adverse impact on visual comfort and efficiency caused by unwanted reflections in the task area, which can hinder the ability to see clearly or cause discomfort, regardless of the source of the glare.

2.1.33 *Surface Reflectance* (*Reflectance*) — The ratio of the luminous flux reflected by an opaque surface (with or without diffusion) to the flux it receives. Here the term is used for lighting. Some symbols used for surface reflectance of common indoor surfaces are:

r_c = reflection factor of ceiling.

r_w = reflection factor of parts of the wall between the working surface and the luminaires.

r_f = reflection factor of floor.

2.1.34 *Reveal* — The side of an opening for a window.

2.1.35 *Room Index* (k_r) — An index relating to the shape of a rectangular interior, according to the formula:

$$k_r = \frac{L \times W}{(L + W)\, H_m}$$

where

L and W = length and width respectively of the interior; and

H_m = mounting height, that is, height of the fittings above the working plane.

NOTES

1 For rooms where the length exceeds 5 times the width, L shall be taken as $L = 5W$.

2 If the surface reflectance of the upper stretch of the walls is less than half the surface reflectance of the ceiling, for indirect or for the greater part of indirect lighting, the value H_m is measured between the ceiling and the working plane.

2.1.36 *Sky Component* (*SC*) — Daylight illuminance at a point on a given plane which is received directly from the sky.

2.1.37 *Solar Load* — The amount of heat received into a building due to solar radiation which is affected by orientation, materials of construction and reflection of external finishes and colour.

2.1.38 *Utilization Factor* (*Coefficient of Utilization*) (μ) — The ratio of the total luminous flux which reaches the working plane (effective luminous flux, ϕ_n) to the total luminous flux of the light sources in the interior (nominal luminous flux, ϕ_o).

2.1.39 *UV-A* — Ultraviolet radiation with wavelengths between 315 and 400 nm. UV-A penetrates the skin more deeply than UV-B and contributes to photoaging, oxidative stress, and potential DNA damage through indirect mechanisms. While it plays a role in skin ageing and long-term health effects, UV-A is significantly less effective for germicidal and disinfection purposes due to its lower energy.

2.1.40 *UV-B* — Ultraviolet radiation with wavelengths between 280 nm and 315 nm. UV-B plays a critical role in the synthesis of pre-vitamin D3 in the human skin upon exposure. It has higher biological activity than UV-A and can also cause sunburn and DNA damage with excessive exposure.

2.1.41 *Visual Field* — The visual field in the binocular which includes an area approximately 120º vertically and 160º horizontally centering on the point to which the eyes are directed. The line joining the point of fixation and the centre of the pupil of each eye is called its primary line of sight.

2.1.42 *Working Plane* — A horizontal plane at a level at which work will normally be done (*see* **4.1.4.4** and **4.1.4.5**).

2.2 Ventilation

2.2.1 *Air Change per Hour* — The amount of air leakage into or out of a building or room in terms of the number of building volume or room volume exchanged.

2.2.2 *Axial Flow Fan* — A fan having a casing in which the air enters and leaves the impeller in a direction substantially parallel to its axis.

2.2.3 *Centrifugal Fan* — A fan in which the air leaves the impeller in a direction substantially at right angles to its axis.

2.2.4 *Contaminants* — Dusts, fumes, gases, mists, vapours and such other substances present in air that are likely to be injurious or offensive to the occupants.

2.2.5 *Dilution Ventilation* — Supply of outside air to reduce the airborne concentration of contaminants in the building.

2.2.6 *Dry Bulb Temperature* — The temperature of the air, read on a thermometer, taken in such a way so as to avoid errors due to radiation.

2.2.7 *Effective Temperature* (*ET*) — An arbitrary index which combines into a single value the effect of temperature, humidity and air movement on the sensation of warmth or cold felt by the human body and its numerical value is that of the temperature of still saturated air which would induce an identical sensation.

2.2.8 *Exhaust of Air* — Removal of air from a building or a room and its disposal outside by means of a mechanical device, such as a fan.

2.2.9 *Fresh Air or Outside Air* — Air of that quality, which meets the criteria of Table 1 and in addition shall be such that the concentration of any contaminant in the air is limited to within one-tenth the threshold limit value (TLV) of that contaminant.

NOTES

1 Where it is reasonably believed that the air of quality is not expected as indicated above, sampling and analysis shall be carried out by a competent authority having jurisdiction and if the outside air of the specified quality is not available, filtration and other treatment devices shall be used to bring its quality to or above the levels mentioned in Table 1. Odour is to be essentially unobjectionable.

2 The above list of contaminants is not exhaustive and available special literature may be referred for data on other contaminants.

2.2.10 *General Ventilation* — Ventilation, either natural or mechanical or both, so as to improve the general environment of the building, as opposed to local exhaust ventilation for contamination control.

2.2.11 *Globe Temperature* — The temperature measured by a thermometer whose bulb is enclosed in a matt black painted thin copper globe of 150 mm diameter. It combines the influence of air temperature and thermal radiations received or emitted by the bounding surfaces.

2.2.12 *Humidification* — The process whereby the absolute humidity of the air in a building is maintained at a higher level than that of outside air or at a level higher than that which would prevail naturally.

Table 1 Maximum Allowable Contaminant Concentrations for Ventilation Air

(*Clause* 2.2.9)

Sl No.	Contaminants	Annual Average (Arithmetic Mean) µg/m^3	Short Term Level (Not to Exceed More than Once a Year) µg/m^3	Averaging Period h
(1)	(2)	(3)	(4)	(5)
i)	Suspended particulates	60	150	24
ii)	Sulphur oxides	80	400	24
iii)	Carbon monoxide	20 000	30 000	8
iv)	Photochemical oxidant	100	500	1
v)	Hydrocarbons (not including methanes)	1 800	4 000	3
vi)	Nitrogen oxide	200	500	24

2.2.13 *Humidity*, *Absolute* — The mass of water vapour per unit volume.

2.2.14 *Humidity*, *Relative* — The ratio of the partial pressure or density of the water vapour in the air to the saturated pressure or density respectively of water vapour at the same temperature.

2.2.15 *Local Exhaust Ventilation* — Ventilation effected by exhaust of air through an exhaust appliance, such as a hood with or without fan located as closely as possible to the point at which contaminants are released, so as to capture effectively the contaminants and convey them through ducts to a safe point of discharge.

2.2.16 *Make-up Air* — Outside air supplied into a building to replace the indoor air.

2.2.17 *Mechanical Ventilation* — Supply of outside air either by positive ventilation or by infiltration by reduction of pressure inside due to exhaust of air, or by a combination of positive ventilation and exhaust of air.

2.2.18 *Natural Ventilation* — Supply of outside air into a building through window or other openings due to wind outside and convection effects arising from temperature or vapour pressure differences (or both) between inside and outside of the building.

2.2.19 *Positive Ventilation* — The supply of outside air by means of a mechanical device, such as a fan.

2.2.20 *Propeller Fan* — A fan in which the air leaves the impeller in a direction substantially parallel to its axis designed to operate normally under free inlet and outlet conditions.

2.2.21 *Spray-Head System* — A system of atomizing water so as to introduce free moisture directly into a building.

2.2.22 *Stack Effect* — Convection effect arising from temperature or vapour pressure difference (or both) between outside and inside of the room and the difference of height between the outlet and inlet openings.

2.2.23 *Tropical Summer Index* (*TSI*) — The temperature of calm air at 50 percent relative humidity which imparts the same thermal sensation as the given environment.

2.2.24 *Threshold Limit Value* (*TLV*) — Refers to air-borne concentration of contaminants currently accepted by the American Conference of Governmental Industrial Hygienists and represents conditions under which it is believed that nearly all occupants may be repeatedly exposed, day after day, without adverse effect.

2.2.25 *Velocity*, *Capture* — Air velocity at any point in front of the exhaust hood necessary to overcome opposing air currents and to capture the contaminants in air at that point by causing the air to flow into the exhaust hood.

2.2.26 *Ventilation* — Supply of outside air into, or the removal of inside air from an enclosed space.

2.2.27 *Wet Bulb Temperature* — The steady temperature finally given by a thermometer having its bulb covered with gauze or muslin moistened with distilled water and placed in an air stream of not less than 4.5 m/s.

3 SITE PLANNING AND BUILDING PLACEMENT

3.1 The aim of site planning and building placement for optimum building orientation is to provide physically and psychologically comfortable living inside the building by creating conditions which suitably and successfully ward off the undesirable effects of severe weather to a considerable extent by judicious use of the recommendations and knowledge of climatic factors.

3.2 Climate Zones

3.2.1 For the purpose of design of buildings, the country may be divided into the major climatic zones as given in Table 2, which also gives the basis of this classification.

Table 2 Classification of Climate

(*Clause* 3.2.1)

Sl No.	Climatic Zone	Mean Monthly Maximum Temperature °C	Mean Monthly Relative Humidity Percent
(1)	(2)	(3)	(4)
i)	Hot-dry	Above 30	Below 55
ii)	Warm-humid	Above 30	Above 55
		Above 25	Above 75
iii)	Temperate	25 to 30	Below 75
iv)	Cold	Below 25	All values
v)	Composite	*See* **3.2.2**	*See* **3.2.2**

The climatic classification map of India is shown in Fig. 2.

3.2.2 Each climatic zone does not have same climate for the whole year; it has a particular season for more than six months and may experience other seasons for the remaining period. A climatic zone that does not have any season for more than six months may be called as composite zone.

3.3 Climatic Factors

From the point of view of lighting and natural ventilation, the following climatic factors influence the optimum orientation of the building:

a) Solar radiation and temperature;

b) Relative humidity; and

c) Prevailing winds.

3.4 Solar Radiation

3.4.1 The best orientation from a solar point of view requires that the building as a whole should receive the maximum solar radiation in winter and the minimum in summer. For practical evaluation, it is necessary to know the duration of sunshine and hourly solar intensity on the various external surfaces on representative days of the seasons. The total direct plus diffused diurnal solar loads per unit area on the vertical surface facing different directions are given in Table 3 for two days in the year, that is, 22 June and 22 December, representative of summer and winter, for latitudes corresponding to some important cities all over India. From Table 3, the total heat intake can be calculated for all possible orientations of the building for these extreme days of summer and winter. Solar load on vertical surfaces of different orientations can be calculated as per the method given in Annex A.

Based upon Survey of India Political map printed in 2002.

Ⓒ Government of India Copyright, 2016

The territorial waters of India extend into the sea to a distance of twelve nautical miles measured from the appropriate baseline.

The interstate boundaries between Arunachal Pradesh, Assam and Meghalaya shown on this map are as interpreted from the North-Eastern Areas (Reorganization) Act, 1971, but have yet to be verified.

The external boundaries and coastlines of India agree with the Record/Master Copy certified by Survey of India.

The responsibility for the correctness of internal details rest with the publisher.

FIG. 2 MAP OF INDIA SHOWING CLIMATIC ZONES

3.4.1.1 Except in cold climatic zone, suitable sun-breakers have to be provided to cut off the incursion of direct sunlight to prevent heat radiation and to avoid glare. A location (latitude) and weather specific approach to sizing of shading devices should consider the annual start and end date of the summer season for the building. Table 3 shows irradiation (W/m^2) received per unit of the facade area in each orientation. Irradiation values maybe used for prioritizing shading devices and other measures of solar protection (for example, planting of vegetation).

Table 3 Total Solar Radiation (Direct Plus Diffused) Incident on Various Surfaces of Buildings, in W/m^2/day, for Summer and for Winter Seasons

(*Clause* 3.4.1, 3.4.1.1 *and* A-2.1.3)

3.5 Relative Humidity and Prevailing Winds

3.5.1 The discomfort due to high relative humidity in air when temperatures are also high can be counteracted, to a great extent, by circulation of air with electric fans or by ventilation. In the past, simultaneously with heavy construction and surrounding *Verandahs* to counter the effect of sun's radiation, there was also an over emphasis on prevailing winds to minimise the adverse effects of high humidity with high temperatures. With the introduction of electric fan to effectively circulate air and owing to taking into account the rise in cost of construction of buildings, emphasis should be on protection from solar radiation where temperatures are very high. When, however, there is less diurnal variation between morning and mean maximum temperatures along with high humidity, as in coastal areas, the emphasis should be on prevailing winds.

3.5.1.1 For the purpose of orientation, it is necessary to study the velocity and direction of the wind at each hour and in each month instead of relying on generalizations of a month or a period or for the year as a whole. This helps to spot the right winds for a particular period of day or night.

3.5.1.2 It is generally found that variation up to 30° with respect to the prevalent wind direction does not materially affect indoor ventilation (average indoor air speed) inside the building.

3.5.2 In hot-dry climate, advantage can be taken of evaporative cooling in summer to cool the air before introducing it into the building. But in warm humid climate, it is desirable either to regulate the rate of air movement with the aid of electric fans or to take advantage of prevailing winds.

3.6 Aspects of Daylighting

The clear design sky concept accounts for the worst-case scenario, making building orientation less critical, except for the need to avoid direct sunlight and glare. However, mutual shading effects from opposite facades and significant vegetation elements shall be considered to maintain effective daylighting. For glare control reference may be made from relevant guidelines/best practices ('Handbook on Sustainability in Buildings'). Daylighting design is supported by three key pillars: daylight availability, sun control, and glare control, all of which are essential to ensure optimal visual comfort and energy efficiency within buildings.

3.7 Spatial and Environmental Considerations in Building Design

Sustainable building design focuses on optimizing the use of natural resources, improving energy efficiency and ensuring occupant well-being. Integrating natural elements such as vegetation and considering the spatial relationships between buildings play a crucial role in enhancing daylight access, ventilation, and thermal comfort, while promoting ecological balance.

The following considerations should guide the integration of these elements into building design:

a) It is suggested to plant tall trees or plants at least as tall as the building around new buildings. This can make the area look aesthetic and help the environment by giving shade, cleaning the air and making the place cooler. It is also better to use plants that naturally grow in the area;

b) Adequate spacing between a building and neighbouring structures is essential for ensuring access to natural light, ventilation, and privacy. The distance between buildings should be planned to minimize overshadowing, reduce light trespass and promote natural airflow, enhancing the overall livability of the area;

c) The orientation of building facades relative to cardinal directions should be planned to optimize solar gain, energy efficiency, and occupant comfort. Facades should maximize natural light while minimizing glare and overheating, contributing to overall energy efficiency and improving thermal performance; and

d) Tree planting in open spaces and streets should be carefully planned to provide shade during the summer season, allow intermittent or seasonal sunlight access, without obstructing natural winds or compromising daylight access. The selected trees should reduce glare, create cool microclimates, and improve air quality. Deciduous trees that shed leaves in winter and retain thick foliage in summer are especially advantageous, particularly for southern and western exposures, allowing maximum sunlight in winter and providing effective shading in summer. Trees with high-density foliage and low gap percentages (for example, *Ashoka*, *Asopalav*) should be placed at a distance proportional to their mature height to avoid obstructing light and airflow. Less dense or deciduous trees (for example, *Gulmohar*, *Amaltas*, *Neem*) may be planted with considerations beyond daylight access, including aesthetics and ecological benefits. In addition, it is recommended that native species of trees be preferred, as identified by the respective state environmental departments, to support region-specific environmental planning.

3.8 Operable Windows and UV Exposure

Operable windows should be provided in habitable spaces to allow for natural ventilation and daylighting. Most glazing types (single pane or double pane) block the UV part of the solar radiation to avoid over-exposure of interiors and occupants to damaging effects of UV radiation. However, some UV exposure has health benefits (UV-B for vitamin D3 production) that occupants can only access if the glass windows are operable. Operable windows should be designed for maximum accessibility to building occupants and direct sun access on facades that receive direct sun, operable windows should be preferred from healthy daylight access point-of-view.

3.9 For detailed information regarding orientation of buildings and recommendations for various climatic zones of country, reference may be made to good practice [D-1(1)].

4 LIGHTING

4.1 Principles of Lighting

4.1.1 *Aims of Good Lighting*

Good lighting is an essential element of building design, serving both visual and non-visual functions to promote occupant comfort, safety and well-being. It should ensure a visually comfortable and functional environment that enhances task performance, supports safe movement and complements the architectural and interior design of spaces. Beyond meeting visual requirements, lighting should also address non-visual impacts by supporting healthy circadian rhythms and aiding in proper eye development, particularly in children. Effective control of glare is critical, as poorly managed glare can lead to visual discomfort, eye strain and headaches. Proper glare management not only improves visual comfort and productivity but also contributes significantly to occupant satisfaction and overall quality of life in buildings.

4.1.1.1 Realization of these aims involves the following:

a) Careful planning of the brightness and colour pattern within both the working areas and the surroundings so that attention is drawn naturally to the important areas, detail is seen quickly and accurately and the room is free from any sense of gloom or monotony (*see* **4.1.4**);

b) Using directional lighting where appropriate to assist perception of task detail and to give good modelling;

c) Controlling direct and reflected glare from light sources to eliminate visual discomfort;

d) In artificial lighting installations, minimizing flicker from certain types of lamps and paying attention to the colour rendering properties of the light;

e) Correlating lighting throughout the building to prevent excessive differences between adjacent areas so as to reduce the risk of accidents; and

f) Installing emergency lighting systems, where necessary.

4.1.2 *Planning the Brightness Pattern*

The brightness pattern seen within an interior may be considered as composed of three main parts – the task itself, immediate background of the task and the general surroundings of walls, ceiling, floor, equipment and furnishings.

The illuminance requirements given in good practice [D-1(2)] for elders and persons with disabilities, shall be complied with in addition to the requirements specified in this Section.

4.1.2.1 In occupations where the visual demands are small, the levels of illumination derived from a criterion of visual performance alone may be too low to satisfy the other requirements. For such situations, therefore, illuminance recommendations are based on standards of welfare, safety and amenity judged appropriate to the occupations; they are also sufficient to give these tasks brightness which ensures that the visual performance exceeds the specified minimum.

4.1.2.2 Where work takes place over the whole utilizable area of room, the illumination over that area should be reasonably uniform and it is recommended that the uniformity ratio (minimum illuminance divided by average illuminance levels) should be not less than 0.7 for the working area.

4.1.2.3 To ensure visual comfort and minimize strain, the illuminance levels within a space should be carefully balanced. Large spatial variations in illuminance around the task or activity area shall be avoided, as they can lead to visual stress and discomfort. The illuminance of the immediate surrounding area shall be related to that of the task area or activity area, ensuring a well-balanced luminance distribution within the visual field. This immediate surrounding area shall be defined as a band with a minimum width of 0.5 m around the task area. While the illuminance of this surrounding area may be lower than that of the task area, it shall not fall below the minimum values specified in Table 4. Additionally, the size and position of the immediate surrounding area shall be clearly stated and documented in the lighting design specifications. Proper planning of these illuminance levels contributes to a visually comfortable and efficient built environment.

Table 4 Relationship of Average Illuminances on Immediate Surrounding to the Average Illuminance on the Task Area or Activity Area

(*Clause* 4.1.2.3)

Sl No. (1)	Average Illuminance on the Task Area or Activity Area lx (2)	Average Illuminance on Immediate Surrounding Areas lx (3)
i)	≥750	500
ii)	500	300
iii)	300	200
iv)	200	150
v)	≤150	equal to task area

4.1.2.4 In indoor workplaces, particularly those devoid of daylight, ensuring adequate illumination beyond the immediate task surroundings is essential for visual comfort and spatial perception. A large area outside the immediate surrounding area, referred to as the background area, shall be illuminated to maintain a well-balanced visual environment. The background area is a horizontal surface at floor level, adjacent to the immediate surrounding area within the limits of the space. It shall have a maintained average illuminance of at least one-third of the illuminance value of the immediate surrounding area. In larger rooms, this background area shall have a minimum width of 3 m to ensure uniformity in lighting. Proper illumination of the background area may help in reducing visual fatigue and enhancing overall workplace efficiency.

4.1.2.5 In case of all buildings and facilities open to and used by the public, including all forms of public housing by the government/civic bodies and private developers, the requirements for visual contrast as given in good practice [D-1(2)] shall also be complied with for ensuring visual comfort for elders and persons with disabilities.

4.1.3 *Glare*

Excessive contrast or abrupt and large changes in brightness produce the effect of glare. When glare is present, the efficiency of vision is reduced and small details or subtle changes in scene cannot be perceived. It may be,

a) direct glare due to light sources within the field of vision;

b) reflected glare due to reflections from light sources or surfaces of excessive brightness; and

c) veiling glare where the peripheral field is comparatively very bright.

4.1.3.1 An example of glare sources in daylighting is the view of the bright sky through a window or skylight, especially when the surrounding wall or ceiling is comparatively dark or weakly illuminated. Glare can be minimized in this case either by shielding the open sky from direct sight by louvers, external hoods or deep reveals, curtains or other shading devices or by cross lighting the surroundings to a comparable level. A gradual transition of brightness from one portion to the other within the field of vision always avoids or minimizes the discomfort from glare.

For electric lamps the minimum shielding angles for lamp luminance shall not be less than the values given in the table below:

Sl No. (1)	*Lamp Luminance* kcd/m^2 (2)	*Minimum Shielding Angle* Degrees (3)
i)	1 to 20	10
ii)	20 to 50	15
iii)	50 to 500	20
iv)	≥500	30

The above mentioned shielding angle should not be applied to luminaries who do not appear in the field of view of a worker during usual work and/or do not give the worker any noticeable disability glare

Table 6 also gives recommended value of quality class of direct glare limitation for different tasks. These are numbers assigned to qualitative limits of direct glare; high, medium and low quality as 1, 2 and 3, respectively. For more details, reference may be made to good practice [D–1(3)].

4.1.4 *Recommended Values of Illuminance*

Table 6 gives the illuminance and lighting performance parameters commensurate with the general standards of lighting described in this Section and related to many occupations and buildings. These are valid under most of the conditions whether the illumination is by daylighting, artificial lighting or a combination of the two. The great variety of visual tasks makes it impossible to list them all and those given should be regarded as representing types of tasks.

The illuminance shall comply with the requirements given in good practice [D-1(2)] for persons with disabilities, in addition to the requirements specified in Table 6.

For comprehending and applying Table 6, reference may be made to **4.1.4.1** to **4.1.7**.

4.1.4.1 *Composition of Table* 6

a) Column (2) lists the reference number for each task area or activity area;

b) Column (3) lists those tasks areas or activities areas, for which specific requirements are given. If the particular task or activity is not listed, the values given for a similar, comparable situation should be adopted. Task areas or activity areas can also be a room, for example, a corridor or resting room;

c) Column (4) gives the required maintained average illuminance $\bar{E}_m$ on the reference surface (*see* **4.1.7**) for the interior (area) in which the task or activity from column (3) is performed;

d) Column (5) gives the minimum illuminance uniformity U_o on the reference surface for the maintained average illuminance $\bar{E}_m$ chosen according to **5**;

e) Column (6) gives the minimum colour rendering indices (R_a) (*see* **4.1.8**) for the situation listed in col (3);

f) Column (7) gives the unified glare rating limits (UGR limits, R_{UGL}) that are applicable to the situation listed in col (3) (*see* **4.1.3**);

g) Column (8) gives the maintained cylindrical illuminance $\bar{E}_{m,z}$ for the recognition of object and people;

h) Column (9) gives the maintained average illuminance on walls $\bar{E}_{m,wall}$; and

j) Column (10) gives the maintained average illuminance on ceilings $\bar{E}_{m,ceiling}$.

4.1.4.2 Indicative list detailing the different locations and tasks are grouped as per the following:

Sl No. (1)	*Location* (2)	*Tasks/Specific Location* (3)
i)	Traffic zones inside buildings	–
ii)	General areas inside buildings	Rest, sanitation and first aid rooms Control rooms Store rooms, cold stores
iii)	Logistics and warehouses	–

Table (*Concluded*)

Sl No. (1)	*Location* (2)	*Tasks/Specific Location* (3)
iv)	Industrial activities and crafts	Agriculture Bakeries Cement, cement goods, concrete, bricks Ceramics, tiles, glass, glassware Chemical, plastics and rubber industry Electrical and electronic industry Food stuffs and luxury food industry Foundries and metal casting Hair dressers Jewellery manufacturing Laundries and dry cleaning Leather and leather goods Metal working and processing Paper and paper goods Power stations Printers Rolling mills, iron and steel works Textile manufacture and processing Vehicle construction and repair Wood working and processing
v)	Offices	–
vi)	Retail premises	–
vii)	Places of public assembly	General areas Restaurants and hotels Theatres, concert halls, cinemas, places for entertainment Trade fairs, exhibition halls Museums Libraries Car parks (indoor)
viii)	Educational premises	Nursery school, play school Educational buildings
ix)	Health care premises	Rooms for general use Staff rooms Wards, maternity wards Examination rooms (general) Eye examination rooms Ear examination rooms Scanner rooms Delivery rooms Treatment rooms (general) Operating areas Intensive care unit Dental clinics/units Laboratories and pharmacies Decontamination rooms Autopsy rooms and mortuaries
x)	Transportation areas	Airports Railway installations

4.1.4.3 The illumination levels recommended in Table 6 are those to be maintained at all time on the task. As circumstances may be significantly different for different interiors used for the same application or for different conditions for the same kind of activity, a range of illuminances is recommended for each type of interior or activity instead of a single value of illuminance. Each range consists of three successive steps of the recommended scale of illuminances. They represent good practice and should be regarded as giving order of illumination commonly required rather than as having some absolute significance. For working interiors, the middle value of each range represents the recommended service illuminance that would be used unless one or more of the factors mentioned below apply.

4.1.4.3.1 The higher value of the range should be used when,

a) unusually low reflectances or contrasts are present in the task;

b) errors are costly to rectify;

c) visual work is critical;

d) accuracy or higher productivity is of great importance; and

e) visual capacity of the worker makes it necessary.

4.1.4.3.2 The lower value of the range may be used when,

a) reflectances or contrast are unusually high;

b) speed and accuracy is not important; and

c) the task is executed only occasionally.

4.1.4.4 Where a visual task is required to be carried out throughout an interior, general illumination level to the recommended value on the working plane is necessary; where the precise height and location of the task are not known or cannot be easily specified, the recommended value is that on horizontal plane 850 mm above floor level.

NOTE — For an industrial task, working plane for the purpose of general illumination levels is that on a work place which is generally 750 mm above the floor level. For certain purposes, such as viewing the objects of arts, the illumination levels recommended are for the vertical plane at which the art pieces are placed.

4.1.4.5 Where the task is localized, the recommended value is that for the task only; it need not, and sometimes should not, be the general level of illumination used throughout the interior. Some processes, such as industrial inspection process, call for lighting of specialized design, in which case the level of illumination is only one of the several factors to be taken into account.

4.1.4.6 In case of all buildings and facilities open to and used by the public, including all forms of public housing by the government/civic bodies and private developers, the minimum illuminance level as given in good practice [D-1(2)] shall also be complied with for ensuring sufficient lighting for accessibility by elders and persons with disabilities.

4.1.5 *Lighting for Movement about a Building*

Most buildings are complexes of working areas and other areas, such as passages, corridors, stairways, lobbies and entrances. The lighting of all these areas shall be properly correlated to give safe movement within the building at all times. In case of all buildings and facilities open to and used by the public, including all forms of public housing by the government/civic bodies and private developers, the illuminance in these areas shall comply with the requirements given in good practice [D-1(2)].

4.1.5.1 *Corridors, passages and stairways*

Transitions from brightly lit work areas to dimly lit corridors, passages, or stairways can pose safety risks, as the human eye requires time to adapt to significant changes in luminance. To mitigate these risks, such transitional spaces should be illuminated uniformly and adequately to ensure clear visibility and safe movement. In areas that are used intermittently, occupancy or motion-sensing lighting controls may be used to conserve energy while ensuring illumination is provided when the space is occupied. Stairways should be designed to prevent direct glare from luminaires and to eliminate harsh shadows that can obscure steps. Tread lighting or integrated step-strip lighting can be used to delineate step edges, especially in low-light environments or emergency egress paths. For outdoor applications, such as industrial catwalks and stairways, lighting should be robust, weather-resistant, and positioned to provide uniform coverage without creating glare. These strategies collectively enhance visual guidance, reduce fall hazards, and improve overall safety in circulation spaces.

4.1.5.2 *Entrances*

The problems of correctly grading the lighting within a building to allow adequate time for adaptation when passing from one area to another area are particularly acute at building entrances. These are given below:

a) By day, people entering a building will be adapted to the very high levels of brightness usually present outdoors and there is risk of accident if entrance areas, particularly any steps, are poorly lighted. This problem may often be overcome by arranging windows to give adequate natural lighting at the immediate entrance, grading to lower levels further inside the entrance area. Where this cannot be done, supplementary artificial lighting should be installed to raise the level of illumination to an appropriate value; and

b) At night it is desirable to light entrance halls and lobbies so that the illumination level reduces towards the exit and so that no bright fittings are in the line of sight of people leaving the building. Any entrance steps to the building should be well-lighted by correctly screened fittings.

4.1.6 *Brightness Appearance of Rooms*

To enhance the brightness appearance and visual comfort of rooms, it is important to define the task or activity areas within the space and assess the type of visual tasks performed. Appropriate lighting criteria, such as maintained average illuminance ($\bar{E}_m$), uniformity ratio (U_o), colour rendering index (R_a) and unified glare rating limit (R_{UGL}), should be selected based on the most demanding tasks. Key room surfaces, including walls and ceilings, should be illuminated to contribute to the perception of brightness. Higher illuminance levels in task areas may be considered to support better visual performance, while the illumination of objects and room surfaces, such as walls ($\bar{E}_{m,wall}$) and ceilings ($\bar{E}_{m,ceiling}$), should be optimized. In spaces with high ceilings or in industrial settings where ceiling lighting is less critical, a lower ceiling illuminance may be acceptable. Table 5 shows the assignment of columns to requirements, as given in **4.1.4.1**.

4.1.7 *Lighting Requirements for Task Areas*, *Activity Areas*, *Room and Space Brightness*

The requirements for task areas and activity areas are given in Table 5. The requirements for the specific tasks and activities are given by $\bar{E}_m$, U_o, R_a and R_{UGL}. The requirements for the space in which the task(s) or activities are carried out are given by $\bar{E}_{m,z}$ for the perception of objects and people within this space and $\bar{E}_{m,wall}$ and $\bar{E}_{m,ceiling}$ for room brightness. The latter are used for designing the room and the space including R_{UGL}. Glare (by R_{UGL}) is dedicated to the space in which a task is carried out.

The first four columns are used for of task area or activity area design and more than one of these areas can occur within one space.

Table 5 Assignment of Columns in Table 6 to Requirements

(*Clauses* 4.1.6 *and* 4.1.7)

Sl No. (1)	Task Area or Activity Area Design (2)				Room or Space Design Requirements (3)		
i)	Task or activity related requirements				Brightness appearance of rooms (**4.1.6**)		
ii)	$\bar{E}_m$ lux	U_o	R_a	R_{UGL}	$\bar{E}_{m,z}$ lux	$\bar{E}_{m,wall}$ lux	$\bar{E}_{m,ceiling}$ lux

where

$\bar{E}_m$ = minimum average illuminance level at defined area;
U_o = uniformity ratio (minimum illuminance/average illuminance);
R_a = colour rendering properties of a light source;
R_{UGL} = unified glare rating limit value;
$\bar{E}_{m,z}$ = maintained average cylindrical illuminance;
$\bar{E}_{m,wall}$ = average illuminance level at wall(s); and
$\bar{E}_{m,ceiling}$ = average illuminance level at ceiling.

In all enclosed places the maintained illuminances on the major surfaces shall have the values specified in Table 6.

NOTES

1 For 33.1, illuminance level mentioned is vertical at bookshelves.

2 For 36.4, 36.7 and 36.23, illuminance level mentioned is vertical illuminance.

3 For 40.1 and 40.2, preferred colour temperature should be 4 000 K to 5 000 K.

4 For 41.1, preferred colour temperature should be 4 000 K to 5 000 K.

5 For 41.2 and 41.3, preferred colour temperature should be 4 000 K to 6 500 K.

6 For 46.1, 46.2, 46.3 and 46.4, additional local lighting to be provided to achieve 10 000 lux to 50 000 lux.

4.1.8 *Colour Rendering*

The colour appearance of light and its colour rendering capability are different aspects of the light sources. A faithful reproduction of an object colour depends on the colour rendering capability of the light source. In 1965, International Commission on Illumination (CIE) developed a quantitative method of assignment of colour rendering property and is denoted as Colour Rendering Index (CRI).

CRI is arrived at by a test by which a number of specified samples are tested under a standard or reference light source and the chromaticity coordinate are plotted on the IE triangle as given in Fig. 7 of Part 2 'Physics of Light, Section 3 Colour' of good practice [D-1(3)]. The same test is repeated under the source under test and corresponding chromaticity coordinate are plotted on the same plot. The difference between the position of each sample for test and standard source is measured to scale. The general colour rendering index (R_a) is obtained by the average value for eight samples {*see* Fig. 8 of Part 2 'Physics of Light, Section 3 Colour' of good practice [D-1(3)]}. For perfect agreement of colour, the R1 value should be 100. In general:

$$R_a = 1/(R1 + R2 + R3 + R4 + \ldots\ldots + R8)$$

The specific colour rendering index for an individual sample is given by:

$$R_i = 100 - 4.6\Delta E_i$$

where

ΔE_i = chromaticity shift on the CIE chromaticity diagram for each sample.

From the obtained value of R_a, as calculated above, the colour rendering shall be evaluated as mentioned in the following table:

Sl No. (1)	*Colour Rendering Evaluated* (2)	R_a (*General Colour Rendering Index*) (3)
i)	Excellent	$90 \leq R_a < 100$
ii)	Good	$80 \leq R_a < 90$
iii)	Moderate	$70 \leq R_a < 80$

4.1.9 For detailed information regarding principles of good lighting, reference may be made to good practice [D-1(4)].

4.2 Daylighting

While the sun is the primary source of natural light, the daylight received at the Earth's surface comprises two components: direct solar illuminance and sky illuminance (diffused light from the sky dome). For effective daylighting design in buildings, direct solar illuminance is typically excluded due to the potential for glare, excessive contrast and thermal discomfort (overheating). Glare from direct sun exposure in occupied zones should be mitigated through appropriate window orientation, sizing and external/internal shading strategies. Accordingly, daylighting strategies should emphasize sky illuminance, which provides diffused uniform light conducive to visual comfort and energy efficiency. By relying on sky illuminance, daylighting design achieves balanced illumination, reduces glare and cooling loads, and supports both visual comfort and sustainable building performance.

4.2.1 The relative amount of sky illuminance at a given point-in-time depends on the position of the sun defined by its altitude, which in turn, varies with the latitude of the locality, the day of the year and the time of the day, as indicated in Table 7.

4.2.2 The external available horizontal sky illuminance (diffuse illuminance) values which are exceeded for about 90 percent of the daytime working hours may be taken as outdoor design illuminance values for ensuring adequacy of daylighting design. The outdoor design sky illuminance varies for different climatic regions of the country. The recommended design sky illuminance values are 6 800 lux for cold climate, 8 000 lux for composite climate, 9 000 lux for warm humid climate, 9 000 lux for temperate climate and 10 500 lux for hot-dry climate. For integration with the artificial lighting during daytime working hours an increase of 500 lux in the recommended sky design illuminance for daylighting is suggested.

4.2.3 The daylight factor is dependent on the sky luminance distribution, which varies with atmospheric conditions. A clear design sky with its non-uniform distribution of luminance is adopted for the purposes of design in this section.

4.2.4 *Components of Daylight Factor*

Daylight factor is the sum of all the daylight reaching on an indoor reference point from the following sources:

a) Direct sky visible from the point;

b) External surfaces reflecting light directly (*see* Note 1) to the point; and

c) Internal surfaces reflecting and inter-reflecting light to the point.

NOTES

1 External surface reflection may be computed approximately only for points at the centre of the room, and for detailed analysis the procedures are complicated and these may be ignored for actual calculations.

2 Each of the three components, when expressed as a ratio or percent of the simultaneous external illuminance on the horizontal plane, defines respectively the sky component (SC), the external reflected component (ERC) and the internal reflected component (IRC) of the daylight factor.

4.2.4.1 The daylight factors on the horizontal plane only are usually taken, as the working plane in a room is generally horizontal; however, the factors in vertical planes should also be considered when specifying daylighting values for special cases, such as daylighting on classrooms, blackboards, pictures and paintings hung on walls.

4.2.5 *Sky Component* (*SC*)

Sky component for a window of any size is computed by the use of the appropriate Table 20, Table 21 and Table 22 of Annex B.

The recommended sky component level should be ensured generally on the working plane at the following positions:

a) At a distance of 3 m to 3.75 m from the window along the central line perpendicular to the window;

b) At the centre of the room if more appropriate; and

c) At fixed locations, such as school desks, black-boards and office tables.

The daylight area of the prescribed sky component should not normally be less than half the total area of the room.

4.2.5.1 The values obtainable from the tables are for rectangular, open unglazed windows, with no external obstructions. The values shall be corrected for the presence of window bars, glazing and external obstructions, if any. This assumes the maintenance of a regular cleaning schedule.

4.2.5.2 *Corrections for window bars*

The corrections for window bars shall be made by multiplying the values read from tables in Annex B by a factor equal to the ratio of the clear opening to the overall opening.

viii)	31ÁN	24	37	50	62	75	82	13	25	37	48	56	56	–	11	21	28	34	36
ix)	34ÁN	25	37	49	62	73	79	12	25	36	46	53	56	–	9	18	26	31	33

4.2.5.3 *Correction for glazing*

Where windows are glazed, the sky components obtained from Annex B shall be reduced by 10 percent to 20 percent, provided the panes are of clear and clean glass. Where glass is of the frosted (ground) type, the sky components read from Annex A may be reduced by 15 percent to 30 percent. In case of tinted or reflective glass the reduction is about 50 percent. Higher indicated correction corresponds to larger windows and/or near reference points. In the case of openings and glazings which are not vertical, suitable correction shall be taken into account.

4.2.5.4 *Correction for external obstructions*

There is no separate correction, except that the values from tables in Annex B shall be read only for the unobstructed portions of the window.

4.2.6 *External Reflected Component* (*ERC*)

The value of the sky component corresponding to the portion of the window obstructed by the external obstructions may be found by the use of methods described in Annex C of good practice [D-1(5)].

These values when multiplied by the correction factors, corresponding to the mean elevation of obstruction from the point in question as given in Table 8, can be taken as the external reflected components for that point.

For method of calculating ERC, reference may be made to accepted standard {*see* examples given in Annex B of good practice [D-1(5)]}.

Table 8 Correction Factor for ERC

(*Clause* 4.2.6)

Sl No. (1)	Mean Angle of Elevation (2)	Correction Factor (3)
i)	5°	0.086
ii)	15°	0.086
iii)	25°	0.142
iv)	35°	0.192
v)	45°	0.226
vi)	55°	0.274
vii)	65°	0.304
viii)	75°	0.324
ix)	85°	0.334

4.2.7 *Internal Reflected Component* (*IRC*)

The component of daylight factor contributed by reflection from the inside surfaces varies directly as the window area and inversely as the total area of internal surfaces and depends on the reflection factor of the floor, wall and roof surfaces inside and of the ground outside. For rooms white-washed on walls and ceiling and windows of normal sizes, the IRC will have sizeable value even at points far away from the window. External obstructions, when present, will proportionately reduce IRC. Where accurate values of IRC are desired, the same may be done in accordance with the good practice [D-1(5)].

4.2.8 *General Principles of Openings to Afford Good Lighting*

4.2.8.1 Generally, while taller openings give greater penetrations, broader openings give better distribution of light. It is preferable that some area of the sky at an altitude of 20º to 25º should light up the working plane.

4.2.8.2 Broader openings may also be equally or more efficient, provided their sills are raised by 300 mm to 600 mm above the working plane.

NOTE — It is to be noted that while placing window with a high sill level might help natural lighting, this is likely to reduce ventilation at work levels. While designing the opening for ventilation also, a compromise may be made by providing the sill level about 150 mm below the head level of workers.

4.2.8.3 For a given penetration, a number of small openings properly positioned along the same, adjacent or opposite walls will give better distribution of illumination than a single large opening. The sky component at any point, due to a number of openings may be easily determined from the corresponding sky component contour charts appropriately superposed. The sum of the individual sky component for each opening at the point gives the overall component due to all the openings. The same charts may also facilitate easy drawing of sky component contours due to multiple openings.

4.2.8.4 Unilateral lighting from side openings will, in general, be unsatisfactory if the effective width of the room is more than 2 to 2.5 times the distance from the floor to the top of the opening. In such cases provision of light shelves is always advantageous.

4.2.8.5 Openings on two opposite sides will give greater uniformity of internal daylight illumination, especially when the room is 7 m or more across. They also minimize glare by illuminating the wall surrounding each of the opposing openings. Side openings on one side and clerestory openings on the opposite side may be provided where the situation so requires.

4.2.8.6 Cross-lighting with openings on adjacent walls tends to increase the diffused lighting within a room.

4.2.8.7 Openings in deep reveals tend to minimize glare effects.

4.2.8.8 Openings shall be provided with *Chajjahs*, louvers, baffles or other shading devices to exclude, as far as possible, direct sunlight entering the room. *Chajjahs*, louvers, etc, reduce the effective height of the opening for which due allowance shall be made. Broad and low openings are, in general, much easier to shade against sunlight entry. Direct sunlight, when it enters, increases the inside illuminance very considerably. Glare will result if it falls on walls at low angles, more so than when it falls on floors, especially when the floors are dark coloured or less reflective.

4.2.8.9 Light control media, such as translucent glass panes (opal or matt) surfaced by grinding, etching or sandblasting, configurated or corrugated glass, certain types of prismatic glass, tinted glass and glass blasts are often used. They should be provided, either fixed or movable outside or inside, especially in the upper portions of the openings. The lower portions are usually left clear to afford desirable view. The chief purpose of such fixtures is to reflect part of the light on to the roof and thereby increase the diffuse lighting within, light up the farther areas in the room and thereby produce a more uniform illumination throughout. They will also prevent the opening causing serious glare discomfort to the occupants but will provide some glare when illuminated by direct sunlight.

4.2.9 *Availability of Daylight in Multistoreyed Block*

Proper planning and layout of building can add appreciably to daylighting illumination inside. Certain dispositions of building masses offer much less mutual obstruction to daylight than others and have a significant relevance, especially when intensive site planning is undertaken. As guidance, the relative availability of daylight in multi-storeyed blocks (up to 4 storeys) of different relative orientations may be taken as given in Table 9.

4.2.10 For specified requirements for daylighting of special occupancies and areas, reference may be made to good practice [D-1(6)]. For using annual climate-based daylight assessment of design, a reference may be made to specialist literature (*see* Note). It also presents a computer simulation-based approach for assessment of adequacy of daylight in indoor spaces.

NOTE — The specialist literature may be Chapter 5 of Energy Conservation and Sustainable Building Code 2024.

Table 9 Relative Availability of Daylight on the Window Plane at Ground Level in Four-Storeyed Building Blocks (Clear Design-Sky as Basis, Daylight Availability Taken as Unity on an Unobstructed Facade, Values are for the Centre of the Blocks)

(*Clause* 4.2.9)

Sl No.	Distance of Separation Between Blocks	Infinitely Long Parallel Blocks	Parallel Blocks Facing Each Other (Length = 2 × Height)	Parallel Blocks facing Gaps Between Opposite Blocks (Length = 2 × Height)
(1)	(2)	(3)	(4)	(5)

ii)	1.0 Ht	0.30	0.32	0.38
iii)	1.5 Ht	0.40	0.50	0.55
iv)	2.0 Ht	0.50	0.60	0.68

NOTE — Ht = Height of the building.

4.3 Artificial Lighting

4.3.1 Artificial lighting may have to be provided,

a) Where the recommended illumination levels have to be obtained by artificial lighting only;

b) To supplement daylighting when the level of illumination falls below the recommended value; and

c) Where visual task may demand a higher level of illumination.

4.3.2 *Artificial Lighting Design for Interiors*

For general lighting purposes, the recommended practice is to design for a level of illumination on the working plane on the basis of the recommended levels for visual tasks given in Table 6 by a method called ‘Lumen method’. In order to make the necessary detailed calculations concerning the type and quantity of lighting equipment necessary, advance information on the surface reflectances of walls, ceilings and floors is required. Similarly, calculations concerning the brightness ratio in the interior call for details of the interior décor and furnishing. Stepwise guidance regarding designing the interior lighting systems for a building using the ‘Lumen method’ is given in **4.3.2.1** to **4.3.2.4**.

4.3.2.1 *Determination of the illumination level*

Recommended value of illumination shall be taken from Table 6, depending upon the type of work to be carried out in the location in question and the visual tasks involved.

4.3.2.2 *Selection of the light sources and luminaires*

The selection of light sources and luminaires depends on the choice of lighting system, namely, general lighting, directional lighting and localized or local lighting.

4.3.2.3 *Determination of the luminous flux*

a) The luminous flux (ϕ) reaching the working plane depends upon the following:

   1) Lumen output of the lamps;

   2) Type of luminaire;

   3) Proportion of the room (room index) (k_r);

   4) Reflectance of internal surfaces of the room;

   5) Depreciation in the lumen output of the lamps after burning their rated life; and

6) Depreciation due to dirt collection on luminaires and room surface.

b) Coefficient of utilization or utilization factor;

1) The compilation of tables for the utilization factor requires a considerable amount of calculations, especially if these tables have to cover a wide range of lighting practices. For every luminaire, the exact light distribution has to be measured in the laboratory and their efficiencies have to be calculated and measured exactly. These measurements comprise,

i) the luminous flux radiated by the luminaires directly to the measuring surface;

ii) the luminous flux reflected and re-reflected by the ceiling and the walls to the measuring surface; and

iii) the inter-reflections between the ceiling and wall which result in the measuring surface receiving additional luminous flux.

All these measurements have to be made for different reflection factors of the ceiling and the walls for all necessary room indices. These tables have also to indicate the maintenance factor to be taken for the luminous flux depreciation throughout the life of an installation due to ageing of the lamp and owing to the deposition of dirt on the lamps and luminaires and room surfaces.

2) The values of the reflection factor of the ceiling and of the wall are as follows:

White and very light colours	0.7
Light colours	0.5
Middle tints	0.3
Dark colours	0.1

For the walls this should be estimated, taking into account the influence of the windows without curtains, shelves, *Almirahs* and doors with different colours, etc.

c) Calculation for determining the luminous flux {see Table 22 of accepted standard [D-1(7)]}

$$E_{\mathrm{av}} = \frac{\mu . \phi}{A}$$

or, $\phi = \frac{E_{\mathrm{a}} A}{\mu}$, for new condition, and

$\phi = \frac{E\mathrm{av}.A}{\mu . d}$, for working condition.

where

E_{av} = average illumination level required on the working plane, in lux;

μ = utilization factor in new conditions;

ϕ = total luminous flux of the light sources installed in the room, in lumens;

A = area of the working plane, in m^2; and

d = maintenance factor.

In practice, it is easier to calculate straightaway the number of lamps or luminaires from:

$$N_{lamp} = \frac{E_{av} . A}{\mu . d . \phi_{lamp}}$$

$$N_{luminaries} = \frac{E_{av} . A}{\mu . d . \phi_{luminaries}}$$

where

N_{lamp} = total number of lamps;

ϕ_{lamp} = luminous flux of each lamp, in lumens;

$N_{\text{luminaires}}$ = total number of luminaires; and

$\phi_{\text{luminaries}}$ = luminous flux of each luminaire, in lumens.

4.3.2.4 *Arrangement of the luminaires*

This is done to achieve better uniformly distributed illumination. The location of the luminaires has an important effect on the utilization factor:

a) In general, luminaires are spaced 'x' metre apart in either direction, while the distance of the end luminaire from the wall is '0.5 x' metre. The distance 'x' is more or less equal to the mounting height 'H_m' between the luminaire and the working plane. The utilization factor tables are calculated for this arrangement of luminaires {*see* Table 22 of the accepted standard [D-1(7)]}.

b) For small rooms where the room index (k_r) is less than 1, the distance 'x' should always be less than H_m, since otherwise luminaires cannot be properly located. In most cases of such rooms, four or two luminaires are placed for good general lighting. If, however, in such rooms only one luminaire is installed in the middle, higher utilization factors are obtained, but the uniformity of distribution is poor. For such cases, references should be made to the additional tables for k_r = 0.6 to 1.25 for luminaires located centrally.

4.3.3 *Artificial Lighting to Supplement Daylighting*

4.3.3.1 The need for general supplementary artificial lighting arises due to diminution of daylighting beyond design hours, that is, for solar altitude below 15° or when dark cloudy conditions occur.

4.3.3.2 The need may also arise for providing artificial lighting during the day in the innermost parts of the building which cannot be adequately provided with daylighting, or when the outside windows are not of adequate size or when there are unavoidable external obstructions to the incoming daylighting.

4.3.3.3 The need for supplementary lighting during the day arises, particularly when the daylighting on the working plane falls below 100 lux and the surrounding luminance drops below 19 cd/m^2.

4.3.3.4 The requirement of supplementary artificial lighting increases with the decrease in daylighting availability. Therefore, conditions near sunset or sunrise or equivalent conditions due to clouds or obstructions, etc, represent the worst conditions when the supplementary lighting is most needed.

4.3.3.5 The requirement of supplementary artificial lighting when daylighting availability becomes poor may be determined from Fig. 3 for an assumed ceiling height of 3.0 m, depending upon floor area, fenestration percentage and room surface reflectance. Cool daylight fluorescent tubes are recommended with semi-direct luminaires. To ensure a good distribution of illumination, the mounting height should be between 1.5 m and 2.0 m above the work plane for a separation of 2.0 m to 3.0 m between the luminaires. Also, the number of lamps should preferably be more in the rear half of the room than in the vicinity of windows. The following steps may be followed for using Fig. 3 for determining the number of fluorescent tubes required for supplementary daylighting:

a) Determine fenestration percentage of the floor area, that is:

$$\frac{Window\ area}{Floor\ area} \times 100$$

b) In Fig. 3, refer to the curve corresponding to the percent fenestration determined above and the set of reflectances of ceiling, walls and floor actually provided; and

c) For the referred curve of Fig. 3 read, along the ordinate, the number of 40 W fluorescent tubes required, corresponding to the given floor area on the abscissa.

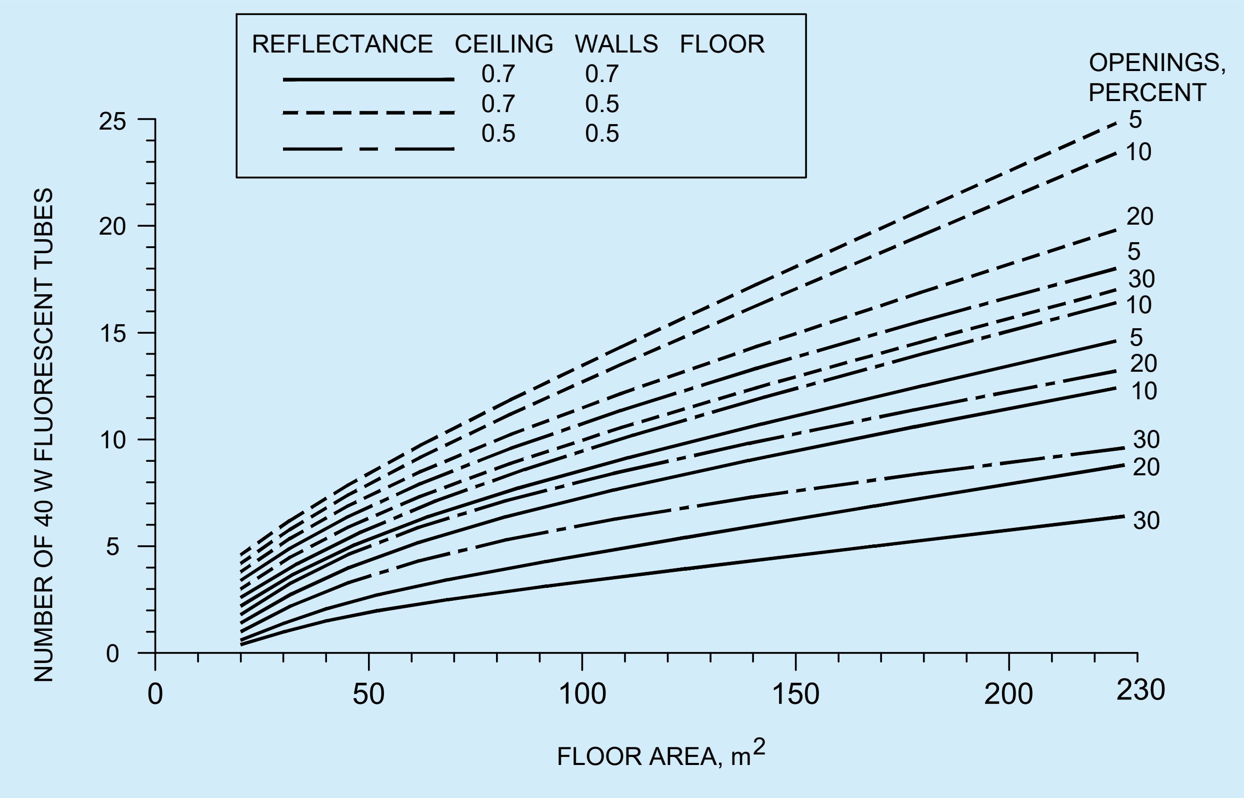

FIG. 3 SUPPLEMENTARY ARTIFICIAL LIGHTING FOR 40 W FLUORESCENT TUBES

4.3.4 For detailed information on the design aspects and principles of artificial lighting, reference may be made to good practice [D-1(4)].

4.3.5 For specific requirements for lighting of special occupancies and areas, reference may be made to good practice [D-1(8)].

4.3.6 Electrical installation aspect for artificial lighting should be in accordance with Part D 'Building Services, Section 2 Electrical and Allied Installations' of this NBCS.

4.4 Energy Conservation in Lighting

4.4.1 A substantial portion of the energy consumed on lighting may be saved by utilization of daylight and rational design of supplementary artificial lights.

4.4.2 Daytime use of artificial lights may be minimized by proper design of windows for adequate daylight indoors. Daylighting design should be according to 4.2.

4.4.3 Fenestration expressed as percentage of floor area required for satisfactory visual performance of a few tasks for different separation to height (*S*/*H*) ratio of external obstructions such as opposite buildings may be obtained from the design nomogram (*see* Fig. 4). The obstructions at a distance of three times their height or more (*S*/*H* > 3) from a window facade are not significant and a window facing such an obstruction may be regarded as a case of unobstructed window.

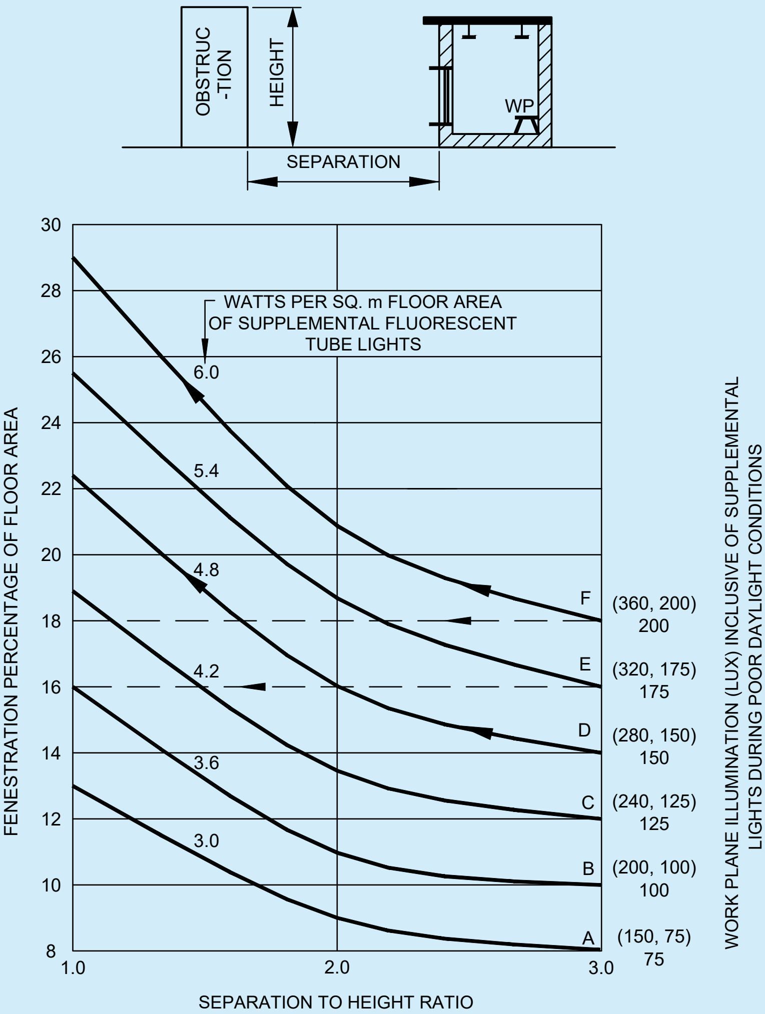

FIG. 4 NOMOGRAPH FOR DAYLIGHTING AND SUPPLEMENTAL LIGHTING DESIGN OF BUILDINGS

4.4.3.1 The nomogram consists of horizontal lines indicating fenestration percentage of floor area and vertical lines indicating the separation to height ratio of external obstructions such as opposite buildings. Any vertical line for separation to height ratio other than already shown in the nomogram (1.0, 2.0 and 3.0) may be drawn by designer, if required. For cases where there is no obstruction, the ordinate corresponding to the value 3.0 may be used. The value of percentage fenestration and separation to height ratio are marked on left hand ordinate and abscissa respectively. The illumination levels are marked on the right hand ordinate. The values given within brackets are the illumination levels on the work plane at centre and rear of the room. The wattage of fluorescent tubes required per square metre of the floor area for different illumination levels is shown on each curve.

4.4.3.2 Following assumptions have been made in the construction of the nomogram:

a) An average interior finish with ceiling white, walls off white and floor grey has been assumed;

b) Ceiling height of 3 m, room depths up to 10 m and floor area between 30 m^2 and 50 m^2 have been assumed. For floor area beyond 50 m^2 and less than 30 m^2, the values of percent fenestration as well as wattage/m^2 should be multiplied by a factor of 0.85 and 1.15, respectively;

c) It is assumed that windows are of metallic sashes with louvers of width up to 600 mm or a *Chhajja* (balcony projection) at ceiling level of width up to 2.0 m. For wooden sashes, the window area should be increased by a factor of about 1.1; and

d) Luminaires emanating more light in the downward direction than upward direction (such as reflectors with or without diffusing plastics) and mounted at a height of 1.5 m to 2.0 m above the work plane have been considered.

4.4.3.3 *Method of use*

The following steps shall be followed for the use of nomogram:

a) *Step* 1 — Decide the desired illumination level depending upon the task illumination requirement in the proposed room and read the value of watt per square metre on the curve corresponding to the required illumination level;

b) *Step* 2 — Fix the vertical line corresponding to the given separation to height ratio of opposite buildings on the abscissa. From the point of intersection of this vertical line and the above curve move along horizontal and read the value of fenestration percent on the left-hand ordinate; and

c) *Step* 3 — If the floor area is greater than 50 m^2 or if it is less than 30 m^2, the value of watt/m^2 as well as fenestration percent may be easily determined for adequate daylighting and supplemental artificial lighting for design purposes. However, if the fenestration provided is less than the required value, the wattage of supplementary artificial lights should be increased proportionately to make up for the deficiency of natural illumination.

4.4.4 For good distribution of day light on the working plane in a room, window height, window width and height of sill should be chosen in accordance with the following recommendations:

a) In office buildings windows of height 1.2 m or more in the centre of a bay with sill level at 1.0 to 1.2 m above floor and in residential buildings windows of height 1.0 m to 1.1 m with sill height as 0.9 m to 0.7 m above floor are recommended for good distribution of daylight indoors. Window width can accordingly be adjusted depending upon the required fenestration percentage of the floor area;

b) If the room depth is more than 10 m, windows should be provided on opposite sides for bilateral lighting; and

c) It is desirable to have a white finish for ceiling and off white (light colour) to white for walls. There is about 7 percent improvement in lighting levels in changing the finish of walls from moderate to white.

4.4.5 For good distribution and integration of daylight with artificial lights the following guidelines are recommended:

a) Employ cool daylight fluorescent tubes for supplementary artificial lighting;

b) Distribute luminaries with a separation of 2 m to 3 m in each bay of 3 m to 4 m width; and

c) Provide more supplementary lights such as twin tube luminaries in work areas where daylight is expected to be poor for example in the rear region of a room having single window and in the central region of a room having windows on opposite walls. In the vicinity of windows only single tube luminaries should be provided.

4.4.6 *Artificial Lighting*

Energy conservation in lighting is affected by reducing wastage and using energy effective lamps and luminaires without sacrificing lighting quality. Measures to be followed comprise utilization of daylight, energy effective artificial lighting design by providing required illumination where needed, turning off artificial lights when not needed, maintaining lighter finishes of ceiling, walls and furnishings, and implementing periodic schedule for cleaning of luminaires and group replacement of lamps at suitable intervals. Choice of light sources with higher luminous efficacy and luminaires with appropriate light distribution is the most effective means of energy saving in lighting. However, choice of light sources also depends on the other lighting quality parameters like colour rendering index and colour temperature or appearance. The choice of light sources type also depends on the desired mounting height in the interiors.

4.4.6.1 *Efficient artificial light sources and luminaires*

Luminous efficacies of some of the lamps used in lighting of buildings are given in Table 10 along with average life in burning hours, colour rendering index and colour temperature. Given the high luminous efficacy that can be achieved with most LED lighting, energy efficiency in lighting can be achieved via space appropriate zoning, identifying the application type (task versus ambient) and careful consideration of lighting quality requirements.

Table 10 Luminous Efficacy, Life, Lumen Maintenance and Colour Rendition of Light Sources

(*Clause* 4.4.6.1)

Sl No. (1)	**Light Source** (2)	**Wattage Range** W (3)	**Efficacy** Lm/W (4)	**Average Life** h (5)	**Lumen Maintenance** (6)	**Colour Rendition** (7)
i)	Incandescent lamps	15 to 200	12 to 20	500 to 1 000	Fair to good	Very good
ii)	Tungsten halogen	300 to 1 500	20 to 27	200 to 2 000	Good to very good	Very good
iii)	Slim line fluorescent	18 to 58	57 to 67	5 000	Fair to good	Good
iv)	High pressure mercury vapour lamps	60 to 1 000	50 to 65	5 000	Very low to fair	Federate
v)	Blended-light lamps	160 to 250	20 to 30	5 000	Low to fair	Federate
vi)	High pressure sodium vapour lamps	50 to 1 000	90 to 125	10 000 to 15 000	Fair to good	Low to good
vii)	Metal halide lamps	35 to 2 000	80 to 95	4 000 to 10 000	Very low	Very good
viii)	Low pressure sodium	10 to 180	100 to 200	10 000 to 20 000	Good to very good	Poor
ix)	LED	0.5 to 2.0	60 to 100	10 000	Very good	Good for white LED

NOTES

1 This includes lamps and wattages currently in use in buildings in India.

2 Luminous efficacy varies with the wattage of the lamp.

3 Average life values are from available Indian Standards. Where Indian Standard is not available, values given are only indicative.

4 For exact values, it is advisable to contact manufacturers.

4.4.6.2 For the same lumen output, it is possible to save 50 percent to 70 percent energy if CFL lamps are replaced with induction lighting, and 40 percent to 60 percent if replaced with LED lamps. Similar energy effective solutions are to be chosen for every application area.

Similarly, with white fluorescent tubes recommended for corridors and staircases, the electrical consumption reduces to 1/4.5 of the energy consumption with incandescent lamps.

4.4.6.3 Efficient luminaire also plays an important role in energy conservation in lighting. The choice of a luminaire should be such that it is efficient not only initially but also throughout its life. Following luminaries are recommended for different locations:

a) For offices semi-direct type of luminaries are recommended so that both the work plane illumination and surround luminance can be effectively enhanced;

b) For corridors and stair cases direct type of luminaries with wide spread of light distributions are recommended; and

c) In residential buildings, glare free wide spread of light distributions are recommended.

4.4.7 *Cleaning Schedule for Window Panes and Luminaires*

Adequate schedule for cleaning of window panes and luminaries will result in significant advantage of enhanced daylight and lumen output from luminaries. Frequent cleaning of windows will tend to reduce the duration over which artificial lights will be used and minimize the wastage of energy. Depending upon the location of the building a cleaning interval of three to six months is recommended for cleaning of luminaires.

4.4.8 *Photocontrols for Artificial Lights*

There is a considerable wastage of electrical energy in lighting of buildings due to carelessness in switching off lights even when sufficient daylight is available indoors. In offices and commercial buildings, occupants may switch on lights in the morning and keep them on throughout the day. When sufficient daylight is available inside, suitable photocontrols can be employed to switch off the artificial lights and thus prevent the wastage of energy.

The photocontrol should have the following features:

a) An integrated photocontrol system continually measures the amount of visible light under the lighting fixture and maintains the lux levels as referred in Table 6;

b) An integrated photocontrol system should maintain six daylighting scenarios that can be adjusted by the user namely; daytime occupied, daytime unoccupied, sunset occupied, sunset unoccupied, night time occupied and night time unoccupied;

c) The photocontrol sensor should have a 60° cone of reference to measure the amount of light on the work surface;

d) Photocontrol, along with supporting lighting based on influx of natural light, should have controls for intelligent 'occupancy based shut-off' system to control which areas need lighting at any moment; and

e) The controls should maintain a decent standard of 'ease of use' for occupants as well as building staff.

4.4.9 *Solar Photovoltaic Systems* (*SPV*)

Solar photovoltaic system enables direct conversion of sunlight into electricity and is viable option for lighting purpose in remote non grid areas. The common SPV lighting systems are:

a) Solar lantern;

b) Fixed type solar home lighting system; and

c) Street lighting system.

4.4.9.1 SPV lighting system should preferably be provided with CFL for energy efficiency.

4.4.9.2 Invertors used in buildings for supplying electricity during the power cut period should be charged through SPV system.

4.4.9.3 Regular maintenance of SPV system is necessary for its satisfactory functioning.

4.4.10 Lighting shelves and light pipes may be explored for utilization and integration in the lighting design.

4.5 Circadian Lighting

Light is fundamental to human health and well-being, extending beyond its role in vision. It is the principal regulator of our circadian rhythm, profoundly influencing visual experience, physiological processes and emotional state. Thus, human-centric lighting, designed for human health and well-being, is essential.

Human physiology is evolved under natural sunlight. Ideally, we would experience abundant daylight exposure, gradually decreasing in the evening, with minimal light at night. Modern indoor lifestyles disrupt this natural rhythm. Optimizing indoor environments to emulate this 24 h light-dark cycle can significantly improve sleep quality and promote rejuvenation, with the added benefit of naturally sustained energy.

The influence of light on human health stems from its role in regulating the internal clock of the body. The circadian rhythm governs diverse physiological functions, from sleep-wake cycles and mood to overall health. This system is orchestrated by the suprachiasmatic nucleus (SCN) in the brain, which relies on consistent light-dark patterns, reflecting our attunement to the diurnal and seasonal rhythms of daylight availability.

The melanopic daylight efficacy ratio (melanopic DER) and melanopic equivalent daylight illuminance (melanopic EDI) provide metrics for assessing light's efficacy in supporting our biological rhythms.

In practice, morning light acts as a critical entraining cue, signalling the body to transition to a state of wakefulness and activity. Exposure to bright light during the day further strengthens the circadian rhythm, which plays a vital role in regulating sleep-wake cycles, daytime engagement, and mood. Conversely, darkness at night-time is essential for promoting restorative sleep, a process crucial for overall health and well-being.

NOTE — The early 2 000 s saw the discovery of specialized retinal light-sensitive cells, peaking at around 480 nm (cyan), leading to the concepts of 'biologically active' or 'circadian light'.

4.5.1 *Need for Supplementary Artificial Circadian Lighting*

Artificial circadian lighting is advised in spaces where permanent day-active occupants spend more than 4 h between sunrise and sunset and do not have a direct line of sight to any external windows from their general working area.

In spaces where artificial circadian lighting cannot be incorporated due to functional considerations (for example, museums, movie theatres), break rooms for day-active permanent occupants may be equipped with circadian lighting.

4.5.2 *Characteristics of Supplementary Artificial Circadian Lighting*

In spaces where supplementary artificial circadian lighting is implemented, it should have the following features:

a) The lighting system shall include dynamic controls that enable gradual changes in light intensity and colour temperature to mimic natural daylight cycles; and

b) Lux levels (vertical illuminance at the occupant positions) shall be modulated based on time of day to ensure sufficient light exposure during the day and reduced exposure in the evening time following the best-practice for circadian lighting design.

4.6 Outdoor Lighting

Outdoor lighting plays a crucial role in ensuring safety, security and functionality in various environments, while contributing to energy conservation and minimizing environmental impacts. To achieve these objectives, outdoor lighting should be designed and managed in accordance with the good practice [D-1(3)], focussing on energy efficiency and minimizing light pollution.

4.6.1 *Lighting Design and Light Zones*

Outdoor lighting designs should adhere to energy efficiency measures and address the requirements of different light zones, as per the good practice [D-1(3)]. The following guidelines should be considered for the design in various zone:

a) *Urban zones* — Lighting intensity should be optimized for high activity areas, using energy-efficient technologies such as LEDs and lighting controls to ensure energy savings;

b) *Suburban zones* — Lighting should be designed for moderate activity areas with an emphasis on reducing unnecessary energy consumption, utilizing dimming controls or motion sensors; and

c) *Rural zones* — Lighting should be kept minimal, ensuring safety while limiting light pollution. Energy-efficient, low-intensity lighting should be implemented.

These zones should serve as guidelines and lighting levels should align with the specific needs of the location while minimizing energy consumption as required by specialist literature.

NOTE — The specialist literature may be Energy Conservation and Sustainable Building Code 2024.

4.6.2 *Energy Efficiency and Light Pollution Mitigation*

To comply with the good practice [D-1(3)] and reduce light pollution, outdoor lighting systems should incorporate the following:

a) *Energy-efficient light sources* — Use of LEDs or other high-efficiency light sources with appropriate lumen output to reduce energy consumption;

b) *Fully shielded and full cut-off fixtures* — These should be implemented to prevent upward light emission and sky glow, focusing light where needed to minimize spill over and improve energy use;

c) *Lighting controls* — The good practice [D-1(3)] compliant controls, such as timers, dimmers, and motion sensors, should be employed to reduce lighting during periods of low activity, contributing to energy savings; and

d) *Luminaire efficacy* — All outdoor lighting luminaires should meet the minimum efficacy requirements as specified in the good practice [D-1(3)] for energy conservation and reduced power consumption.

4.6.3 *Effects of Light Pollution on Life*

Excessive outdoor lighting, if not properly controlled, may have adverse effects on human, animal and plant life:

a) *Human health* — Exposure to artificial light at night can disrupt circadian rhythms, leading to potential health risks such as sleep disorders and increased stress. Lighting design should prioritize human well-being by controlling glare and unnecessary brightness;

b) *Animal life* — Wildlife, particularly nocturnal species, may experience disruptions in natural behaviours, such as feeding and mating, due to poorly managed artificial lighting. The good practice [D-1(3)] compliant lighting should minimize impact on ecosystems; and

c) *Plant life* — Artificial lighting may affect plant growth cycles, leading to ecological imbalance. Properly designed lighting should reduce this risk by controlling light spill and adhering to the lighting recommendations of good practice [D-1(3)].

5 VENTILATION

5.1 General

Natural ventilation of buildings is required to supply outdoor air for the respiration of occupants, to remove any products of combustion or other contaminants in the air and to provide such thermal environments as will assist in the maintenance of heat balance of the body in order to prevent discomfort and injury to the health of the occupants. The natural ventilation through building envelope elements such as operable windows, skylights and ventilators help maintain the desired quality of air and thermal comfort conditions when outdoor air and thermal environments are conducive to the cause.

5.2 Design Considerations

5.2.1 *Respiration*

Supply of fresh air to provide oxygen for the human body for elimination of waste products and to maintain carbon dioxide concentration in the air within safe limits rarely calls for special attention as enough outside air for this purpose normally enters the areas of occupancy through crevices and other openings.

In normal habitable rooms devoid of smoke generating source, the content of carbon dioxide in air rarely exceeds 0.5 percent to 1 percent and is, therefore, incapable of producing any ill effect. The amount of air required to keep the concentration down to 1 percent is very small. The change in oxygen content is also too small under normal conditions to have any ill effects; the oxygen content may vary quite appreciably without noticeable effect, if the carbon dioxide concentration is unchanged.

5.2.2 *Vitiation by Body Odours*

Where no products of combustion or other contaminants are to be removed from air, the amount of fresh air required for dilution of inside air to prevent vitiation of air by body odours, depends on the air space available per person and the degree of physical activity; the amount of air decreases as the air space available per person increases, and it may vary from 20 m^3 to 30 m^3 per person per hour. In rooms occupied by only a small number of persons such an air change will automatically be attained in cool weather by normal leakage around windows and other openings and this may easily be secured in warm weather by keeping the openings open.

No standards have been laid down under the *Factories Act*, 1948 as regards the amount of fresh air required per worker or the number of air changes per hour. Section 16 of the *Factories Act*, 1948 relating to over-crowding requires that at least 14 m^3 to 16 m^3 of space shall be provided for every worker and for the purpose of that section no account shall be taken of any space in a work room which is more than 4.25 m above the floor level.

NOTE — Vitiation of the atmosphere can also occur in factories by odours given off due to contaminants of the product itself, say for example, from tobacco processing in a '*Beedi*' factory. Here the ventilation will have to be augmented to keep odours within unobjectionable levels.

5.2.2.1 *Recommended values for air changes*

The standards of general ventilation are recommended/based on maintenance of required oxygen, carbon dioxide and other air quality levels and for the control of body odours when no products of combustion or other contaminants are present in the air; the values of air changes should be as follows:

Sl No. (1)	*Application* (2)	*Air Change per Hour* (3)

NOTES

1 The ventilation rates may be increased by 50 percent where heavy smoking occurs or if the room is below the ground.

2 The ventilation rate shall be as per **14.2.1** of Part D 'Building Services, Section 3 Air Conditioning, Heating and Mechanical Ventilation' of this NBCS.

5.2.3 *Heat Balance of Body*

Especially in hot weather, when the thermal environment inside the room is worsened by the heat given off by machinery, occupants and other sources, the prime need for ventilation is to provide such a thermal environment as will assist in the maintenance of heat balance of the body in order to prevent discomfort and injury to health. Excess of heat either from increased metabolism due to physical activity of persons or gains from a hot environment has to be offset to maintain normal body temperature (approximately 37 °C). Heat exchange of the human body with respect to the surroundings is determined by the temperature and humidity gradient between the skin and the surroundings and other factors, such as the age of person, clothing, etc and the latter depends on air temperature (dry bulb temperature), relative humidity, radiation from the solid surroundings and rate of air movement. The volume of outside air to be circulated through the room is, therefore, governed by the physical considerations of controlling the temperature, air distribution or air movement. Air movement and air distribution may, however, be achieved by recirculation of the inside air rather than bringing in all outside air. However, fresh air supply or the circulated air will reduce heat stress by dissipating heat from the body by evaporation of the sweat, particularly when the relative humidity is high and the air temperature is near body temperature.

5.2.3.1 *Indices of thermal comfort*

Thermal comfort is that condition of a thermal environment under which a person can maintain a body heat balance at normal body temperature and without perceptible sweating. Limits of comfort vary considerably according to studies carried out in India and abroad.

The thermal indices which find applications for Indian climate are as follows:

- a) Effective temperature (ET);
- b) Tropical summer index (TSI); and
- c) Operative temperature based adaptive thermal comfort.

5.2.3.1.1 *Effective temperature* (*ET*)

Effective temperature is defined as the temperature of still, saturated air which has the same general effect upon comfort as the atmosphere under investigation. Combinations of temperature, humidity and wind velocity producing the same thermal sensation in an individual are taken to have the same effective temperature.

Initially two scales were developed, one of which referred to men stripped to the waist and called the basic scale. The other applies to men fully clad in indoor clothing and called the normal scale of effective temperature. Bedfort (1946) proposed the use of globe temperature reading instead of the air temperature reading to make allowance for the radiant heat. This scale is known as the corrected effective temperature (CET) scale. No allowance, however, was made for the different rates of energy expenditure. The scale was compiled only for men either seated or engaged in light activity.

Figure 5 represents the corrected effective temperature nomogram. The CET can be obtained by connecting the appropriate points representing the dry bulb (or globe) and wet bulb temperatures and reading the CET value at the intersection of this line with the relevant air velocity curve from the family of curves for various air velocities running diagonally upwards from left to right.

The effective temperature scale may be considered to be reasonably accurate in warm climates where the heat stress is not high but it may be misleading at high levels of heat stress. There appears to be an inherent error in this scale if used as an index of physiological strain, the error increasing with the severity of the environmental conditions. For low and moderate degrees of heat stress, the effective temperature scales appear to assess climatic heat stress with an accuracy which is acceptable for most practical purposes.

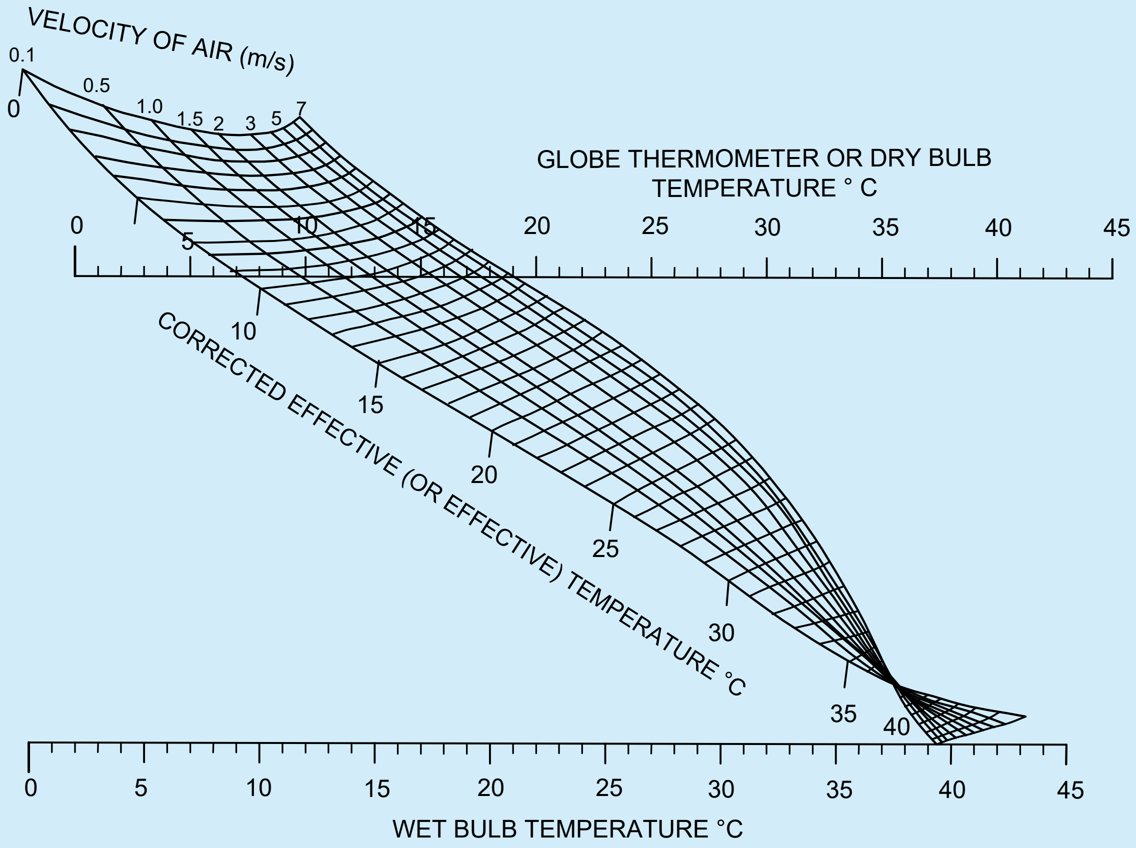

FIG. 5 CORRECTED EFFECTIVE TEMPERATURE NOMOGRAM

5.2.3.1.2 *Tropical Summer Index* (*TSI*)

The TSI is defined as the temperature of calm air, at 50 percent relative humidity which imparts the same thermal sensation as the given environment. The 50 percent level of relative humidity is chosen for this index as it is a reasonable intermediate value for the prevailing humidity conditions. Mathematically, TSI (°C) is expressed as:

$$\text{TSI} = 0.745\text{t}_{\text{g}} + 0.308\text{t}_{\text{w}}\text{-}2.06\sqrt{v + 0.841}$$

where

t_w = wet bulb temperature, in °C;
t_g = globe temperature, in °C; and
v = air speed, in m/s.

The thermal comfort of a person lies between TSI values of 25 °C and 30 °C with optimum condition at 27.5 °C. Air movement is necessary in hot and humid weather for body cooling. A certain minimum desirable wind speed is needed for achieving thermal comfort at different temperatures and relative humidity. Such wind speeds are given in Table 11. These are applicable to sedentary work in offices and other places having no noticeable sources of heat gain. Where somewhat warmer conditions are prevalent, such as in godowns and machine shops and work is of lighter intensity, and higher temperatures can be tolerated without much discomfort, minimum wind speeds for just acceptable warm conditions are given in Table 12. For obtaining values of indoor wind speed above 2.0 m/s, mechanical means of ventilation may have to be adopted (*see also* Part D 'Building Services, Section 3 Air Conditioning, Heating and Mechanical Ventilation' of this NBCS).

The warmth of the environment was found tolerable between 30 °C and 34 °C (TSI), and too hot above this limit. On the lower side, the coolness of the environment was found tolerable between 19 °C and 25 °C (TSI) and below 19 °C (TSI), it was found too cold.

5.2.4 *Design of Indoor Conditions as per Adaptive Thermal Comfort Model*

Air conditioning systems for interior spaces intended for human occupancy should be sized for not more than 26 °C for cooling and for not less than 18 °C for heating at an occupied level. Design based on an adaptive thermal comfort model can play a major role in reducing energy use whilst maintaining the comfort, productivity and well-being of occupants. This approach recognizes that people's thermal comfort needs depend on their past and present context and that these needs vary with the outdoor environmental conditions of their location.

People living year-round in air-conditioned spaces are likely to develop high expectations for homogeneity and cool temperatures and may become quite critical if thermal conditions deviate from the centre of the comfort zone

---

1) None.

2) Higher than those acceptable in practice.

they have come to expect. In contrast, people who live or work in naturally ventilated buildings, can control their immediate interior spaces and get accustomed to variable indoor thermal conditions that reflect local patterns of daily and seasonal climate changes. Their thermal perceptions, preferences, as well as tolerances, are likely to extend over a wider range of temperatures. It allows buildings to operate within broader temperature bands. The specification of a broader comfort band suited to the Indian context has the potential to reduce the use of energy-intensive space cooling for buildings in India. The provisions here deal with the adaptive thermal comfort model, which differentiates the thermal response of occupants in air-conditioned and naturally ventilated buildings. It is imperative to specify indoor comfort conditions separately for buildings depending upon their operation, namely, air-conditioned buildings as well as naturally ventilated buildings:

a) Operative temperature is a more suitable index to measure thermal comfort in a building having low indoor air velocities since the index also accounts for the impact of building surface temperatures (radiant temperatures) on human comfort. Indoor operative temperature, for sedentary activities, can be approximated as an arithmetic mean of indoor air and radiant temperatures. For operating an air conditioning system based on operative temperature, the prevalent conditions along with the historical outdoor trend can be used to derive suitable operative temperature limits. Typical climatic conditions of various Indian cities are in the public domain; and

b) In case of buildings having higher indoor air velocity (more than 0.5 m/s), an effective temperature-based approach is recommended since, in addition to all factors considered in operative temperature, it also takes into account heat dissipation from the human body through convective heat transfer. High air velocity can allow keeping higher air temperature without compromising thermal comfort. However, it is also suggested to keep in consideration noise and other effects of high indoor air velocity. For annual indoor design conditions as per the adaptive model, for Indian cities, reference may be made to Annex A of Part D 'Building Services, Section 3 Air Conditioning, Heating and Mechanical Ventilation' of this NBCS. These are indicative, simplified values. They have been derived using typical meteorological year (TMY) files. More accurate design conditions can be derived using the following equations.

5.2.4.1 *Design Conditions for Commercial Buildings*

It is recommended to use the below-mentioned set of adaptive thermal comfort equations for commercial buildings. Equations (a) to (b) are best suited for the 30 day outdoor running mean temperatures between 13 °C and 38.5 °C:

a) For naturally ventilated (NV) commercial buildings — The following equation should be used for the design and operation of naturally ventilated (NV) buildings. It indicates that occupants in NV buildings thermally adapt to the outdoor temperature of their location:

$$Indoor\ operative\ temperature = (0.54 \times Outdoor\ temperature) + 12.83$$

where, indoor operative temperature (in °C) is the neutral temperature, and outdoor temperature is the 30 day outdoor running mean air temperature (in °C). The 90 percent acceptability range for naturally ventilated buildings is ± 2.38 °C.

b) For mixed-mode (MM) operation commercial buildings — Mixed-mode buildings, where HVAC is operated only during extreme outdoor conditions, are becoming prevalent in India. The occupants in mixed-mode buildings are more adaptive when compared to those in air conditioned buildings and somewhat less adaptive compared to occupants in naturally ventilated buildings:

$$Indoor\ operative\ temperature = (0.28 \times Outdoor\ temperature) + 17.87$$

where, indoor operative temperature (in °C) is the neutral temperature, and outdoor temperature is the 30 day outdoor running mean air temperature (in °C). The 90 percent acceptability range for mixed-mode buildings is ± 3.46 °C.

5.2.4.2 *Design Conditions for Residential Buildings*

The following equation should be used for determining adaptive thermal comfort in residential buildings, applicable for outdoor running mean temperatures between 7 °C and 33 °C. It is recommended to use the below-mentioned adaptive thermal comfort equation for residential buildings, for all operation modes:

$$Indoor\ operative\ temperature = (0.42 * Outdoor\ temperature) + 17.45$$

where, indoor operative temperature (in °C) is neutral temperature, and outdoor temperature is the 30 day outdoor running mean air temperature (in °C). The 90 percent acceptability range for conditioned buildings is ± 2.15 °C.

The adaptive comfort values derived using equations given in **5.2.4.1** for commercial, and the equation given in **5.2.4.2** for residential buildings are best suited for indoor relative humidity conditions (RH in percentage) between 25 percent and 75 percent.

5.2.5 *Minimum Outside Fresh Air*

Minimum outside fresh air applicable to only fully air-conditioned buildings. Table 13 prescribes minimum supply rates of acceptable outdoor air required for acceptable indoor air quality. These requirements for ventilation of health care facilities (hospitals, nursing and convalescent homes) are separately covered in Table 14. These values have been prescribed to dilute human bio effluents and other contaminants with an adequate margin of safety and to account for health variations among people and varied activity levels. The values prescribed in the table should be used in conjunction with the accompanying notes. Naturally ventilated spaces and mixed mode spaces, while operating in naturally ventilated mode, will have to rely on outdoor air using fenestration systems. The quantity and distribution of introduced fresh air should take into account the natural infiltration of the building. The proportion of fresh air introduced into air conditioned building may be varied to achieve economical and efficient operation. When the fresh air can provide a useful cooling effect, the quantity should be controlled through an air-side economizer to balance the cooling demand. However, when the air is too warm or humid the quantity may be reduced to a minimum to reduce the cooling load.

5.2.5.1 *Air class characteristic*

The following are the characteristics of the four air classes:

a) Class 1 — Air with low contaminant concentration, low sensory-irritation intensity and inoffensive odour;

b) Class 2 — Air with moderate contaminant concentration, mild sensory-irritation intensity, or mildly offensive odours. This air also includes air that is not necessarily harmful or objectionable but that is inappropriate for transfer or recirculation to spaces used for different purposes;

c) Class 3 — Air with significant contaminant concentration, significant sensory-irritation intensity, or offensive odour; and

d) Class 4 — Air with highly objectionable fumes or gases or with potentially dangerous particles, bio aerosols, or gases, at concentrations high enough to be considered harmful.

NOTES

1 The rates in this table are based on all other applicable requirements being met.

2 This table applies to no-smoking areas only. Rates for smoking-permitted spaces shall be determined using other methods.

3 Volumetric airflow rates are based on an air density of 1.2 kg of dry air/m^3, which corresponds to dry air at a barometric pressure of 1 atm (101.3 kPa) and an air temperature of 21 °C. Rates may be adjusted for actual density but such adjustment is not required for compliance with this standard.

4 Actual occupant density should be considered, the default occupant density shall be used only when actual occupant density is not known. Default combined outdoor air (per person) rate is based on the default occupant density.

5 If the occupancy category for a proposed space or zone is not listed, the requirements for the listed occupancy category that is most similar in terms of occupant density, activities and building construction shall be used.

6 For high school and college libraries, use values shown for public assembly spaces-libraries.

7 The prescribed value may not be sufficient when stored materials include those having potentially harmful emissions.

8 Default occupancy for dwelling units shall be two persons for studio and one-bedroom units, with one additional person for each additional bedroom.

9 Air from one residential dwelling shall not be recirculated or transferred to any other space outside of that dwelling.

10 When combustion equipment is intended to be used on the playing surface, additional dilution ventilation and/or source control shall be provided.

11 The prescribed value does not allow for humidity control. Additional ventilation or dehumidification may be required to remove moisture.

12 The prescribed value does not include special exhaust for stage effects, for example, dry ice vapours, smoke.

---

[1] Net occupiable space.

5.2.6 There will be a limit of heat tolerance when air temperatures are excessive and the degree of physical activity is high. This limit is determined when the bodily heat balance is upset, that is, when the bodily heat gain due to conduction, convection and the radiation from the surroundings exceeds the bodily heat loss, which is mostly by evaporation of sweat from the surface of the body. The limits of heat tolerance for Indian workers are based on the study conducted by the Chief Adviser Factories, Government of India, Ministry of Labour and are given in his report on Thermal Stress in Textile Industry (Report No. 17) issued in 1956. According to this report, where workers in industrial buildings wearing light clothing are expected to do work of moderate severity with the energy expenditure in the range 273 W to 284 W, the maximum wet bulb temperature shall not exceed 29 °C and adequate air movement subject to a minimum air velocity of 30 m/min shall be provided, and in relation to the dry bulb temperature, the wet bulb temperature of air in the work room, as far as practicable, shall not exceed that given in Table 15.

Table 15 Maximum Permissible Wet Bulb Temperatures for Given Dry Bulb Temperatures

(*Clause* 5.2.6)

Sl No.	Dry Bulb Temperature °C	Maximum Wet-Bulb Temperature °C
(1)	(2)	(3)
i)	30	29.0
ii)	35	28.5
iii)	40	28.0
iv)	45	27.5
v)	50	27.0

NOTES

1 These are limits beyond which the industry should not allow the thermal conditions to go for more than 1 h continuously. The limits are based on a series of studies conducted on Indian subjects in psychrometric chamber and on other data on heat casualties in earlier studies conducted in Kolar Gold Fields and elsewhere.

2 Figures given in this table are not intended to convey that human efficiency at 50 °C will remain the same as at 30 °C, provided appropriate wet bulb temperatures are maintained. Efficiency decreases with a rise in the dry bulb temperature as well, as much as possible. Long exposures to temperatures of 50 °C dry bulb/27 °C wet bulb may prove dangerous.

3 Refrigeration or some other method of cooling is recommended in all cases where conditions would be worse than those shown in this table.

5.3 Methods of Ventilation

General ventilation involves providing a building with relatively large quantities of outside air in order to improve general environment of the building. This may be achieved in one of the following ways:

a) Natural supply and natural exhaust of air;

b) Natural supply and mechanical exhaust of air;

c) Mechanical supply and natural exhaust of air; and

d) Mechanical supply and mechanical exhaust of air.

5.3.1 *Control of Heat*

Although it is recognized that general ventilation is one of the most effective methods of improving thermal environmental conditions in factories, in many situations, the application of ventilation should be preceded by and considered along with some of the following other methods of control. This would facilitate better design of buildings for general ventilation, either natural or mechanical or both and also reduce their cost.

5.3.1.1 *Isolation*

Sometimes it is possible to locate heat producing equipment, such as furnaces in such a position as would expose only a small number of workers to hot environment. As far as practicable, such sources of heat in factories should be isolated.

In situations where relatively few people are exposed to severe heat stress and their activities are confined to limited areas as in the case of rolling mill operators and crane operators, it may be possible to enclose the work areas and provide spot cooling or supply conditioned air to such enclosures.

5.3.1.2 *Insulation*

A considerable portion of heat in many factories is due to the solar radiation falling on the roof surfaces, which, in turn, radiate heat inside the building. In such situations, insulations of the roof or providing a false ceiling or double roofing would be very effective in controlling heat. Some reduction can also be achieved by painting the roof in heat reflective shades.

Hot surfaces of equipment, such as pipes, vessels, etc, in the building should also be insulated to reduce their surface temperature.

5.3.1.3 *Substitution*

Sometimes, it is possible to substitute a hot process by a method that involves application of localized or more efficiently controlled method of heating, examples include induction hardening instead of conventional heat treatment, cold riveting or spot welding instead of hot riveting, etc.

5.3.1.4 *Radiant shielding*

Hot surfaces, such as layers of molten metal emanate radiant heat, which can best be controlled by placing a shield having a highly reflecting surface between the source of heat and the worker, so that a major portion of the heat falling on the shield is reflected back to the source. Surfaces such as of tin and aluminium have been used as materials for shields. The efficiency of the shield does not depend on its thickness, but on the reflectivity and emissivity of its surface. Care should be taken to see that the shield is not heated up by conduction and for this purpose adequate provision should be made for the free flow upwards of the heated air between the hot surface and the shield by leaving the necessary air space and providing opening at the top and the bottom of the sides.

5.3.2 *Volume of Air Required*

The volume of air required shall be calculated by using both the sensible heat and latent heat gain as the basis. The larger of the two values obtained should be used in actual practice.

In places without sufficient wind speeds and/or in buildings where effective cross ventilation is not possible due to the design of the interior, the indoor air may be exhausted by a fan, with outdoor air entering the building through the open windows.

5.3.2.1 *Volume of air required for removing sensible heat*

When the amount of sensible heat given off by different sources, namely, the sun, the manufacturing processes, machinery, occupants and other sources, is known and a suitable value for the allowable temperature rise is assumed, the volume of outside air to be provided for removing the sensible heat may be calculated from:

$$Q_1 = \frac{2.976\,8\,K_s}{t}$$

where

Q_1 = quantity of air, in m^3/h;

K_s = sensible heat gained, in W; and

t = allowable temperature rise, in °C.

5.3.2.2 Temperature rise refers mainly to the difference between the air temperatures at the outlet (roof exit) and at the inlet openings for outside air. As very little data exist on allowable temperature rise values for supply of outside air in summer months, the values given in Table 16 related to industrial buildings may be used for general guidance.

Table 16 Allowable Temperature Rise Values

(*Clause* 5.3.2.2)

Sl No.	Height of Outlet Opening m	Temperature Rise °C
(1)	(2)	(3)
i)	6	3 to 4.5
ii)	9	4.5 to 6.5
iii)	12	6.5 to 11

NOTES

1 The conditions are limited to light or medium heavy manufacturing processes, freedom from radiant heat and inlet openings not more than 3 m to 4.5 m above floor level.

2 At the working zone between floor level and 1.5 m above floor level, the recommended maximum allowable temperature rise for air is 2 °C to 3 °C above the air temperature at the inlet openings.

5.3.2.3 *Volume of air required for removing latent heat*

If the latent heat gained from the manufacturing processes and occupants is also known and a suitable value for the allowable rise in the vapour pressure is assumed, the volume of air to be provided to remove the latent heat may be calculated from:

$$Q_2 = \frac{4\ 127.26\,K_1}{h}$$

where

Q_2 = quantity of air, in m^3/h;

K_1 = latent heat gained, in W; and

h = allowable vapour pressure difference, in mm of mercury.

NOTE — In majority of the cases, the sensible heat gain will far exceed the latent heat gain, so that the amount of outside air to be drawn by ventilating equipment can be calculated on the basis of the equation given in **5.3.2.1**.

5.3.2.4 Ventilation is also expressed as m^3/h/m^2 of floor area. This relationship fails to evaluate the actual heat relief provided by a ventilation system, but it does give a relationship which is independent of building height. This is a more rational approach, because, with the same internal load, the same amount of ventilation air, properly applied to the work zone with adequate velocity, will provide the desired heat relief quite independently of the ceiling height of the space, with few exceptions. Ventilation rates of 30 m^3/h/m^2 to 60 m^3/h/m^2 have been found to give good results in many plants.

5.4 Natural Ventilation

The rate of ventilation by natural means through windows or other openings depends on,

a) direction and velocity of wind outside and sizes and disposition of openings (wind action); and

b) convection effects arising from temperature of vapour pressure difference (or both) between inside and outside the room and the difference of height between the outlet and inlet openings (stack effect).

5.4.1 *Ventilation of Non-Industrial Buildings*

Ventilation in non-industrial buildings due to stack effect, unless there is a significant internal load, could be neglected, except in cold regions and wind action may be assumed to be predominant.

5.4.1.1 In hot dry regions, the main problem in summer is to provide protection from sun's heat so as to keep the indoor temperature lower than those outside under the sun. For this purpose, windows and other openings are generally kept closed during day time and only minimum ventilation is provided for the control of odours or for removal of products of combustion.

5.4.1.2 In warm humid regions, the problem in the design of non-industrial buildings is to provide free passage of air to keep the indoor temperature as near to those outside in the shade as possible, and for this purpose the buildings are oriented to face the direction of prevailing winds and windows and other openings are kept open on both windward and leeward sides.

5.4.1.3 In winter months in cold regions, the windows and other openings are generally kept shut, particularly during night; and ventilation necessary for the control of odours and for the removal of products of combustion can be achieved either by stack action or by some infiltration of outside air due to wind action.

5.4.2 *Ventilation of Industrial Buildings*

In providing natural ventilation of all industrial buildings having significant internal heat loads due to manufacturing process, proper consideration should be given to the size and distribution of windows and other inlet openings in relation to outlet openings so as to give, with due regard to orientation, prevailing winds, size and configuration of the building and manufacturing processes carried on, maximum possible control of thermal environment.

5.4.2.1 In the case of industrial buildings wider than 30 m, the ventilation through windows may be augmented by roof ventilation.

5.4.3 *Design Guidelines for Natural Ventilation*

5.4.3.1 *By wind action*

a) A building need not necessarily be oriented perpendicular to the prevailing outdoor wind; it may be oriented at any convenient angle between 0° and 30° without losing any beneficial aspect of the breeze. If the prevailing wind is from east or west, building may be oriented at 45° to the incident wind so as to diminish the solar heat without much reduction in air motion indoors;

b) Inlet openings in the buildings should be well distributed and should be located on the windward side at a low level, and outlet openings should be located on the leeward side. Inlet and outlet openings at high levels may only clear the top air at that level without producing air movement at the level of occupancy;

c) Maximum air movement at a particular plane is achieved by keeping the sill height of the opening at 85 percent of the critical height (such as head level) for the following recommended levels of occupancy:

    1) For sitting on chair 0.75 m;

    2) For sitting on bed 0.60 m; and

    3) For sitting on floor 0.40 m.

d) Inlet openings should not as far as possible be obstructed by adjoining buildings, trees, sign boards or other obstructions or by partitions inside in the path of air flow;

e) In rooms of normal size having identical windows on opposite walls the average indoor air speed increases rapidly by increasing the width of window up to two-third of the wall width; beyond that the increase is in much smaller proportion than the increase of the window width. The air motion in the working zone is maximum when window height is 1.1 m. Further increase in window height promotes air motion at higher level of window, but does not contribute additional benefits as regards air motion in the occupancy zones in buildings;

f) Greatest flow per unit area of openings is obtained by using inlet and outlet openings of nearby equal areas at the same level;

g) For a total area of openings (inlet and outlet) of 20 percent to 30 percent of floor area, the average indoor wind velocity is around 30 percent of outdoor velocity. Further increase in window size increases the available velocity but not in the same proportion as shown in Fig. 6. In fact, even under most favourable conditions the maximum average indoor wind speed does not exceed 40 percent of outdoor velocity;

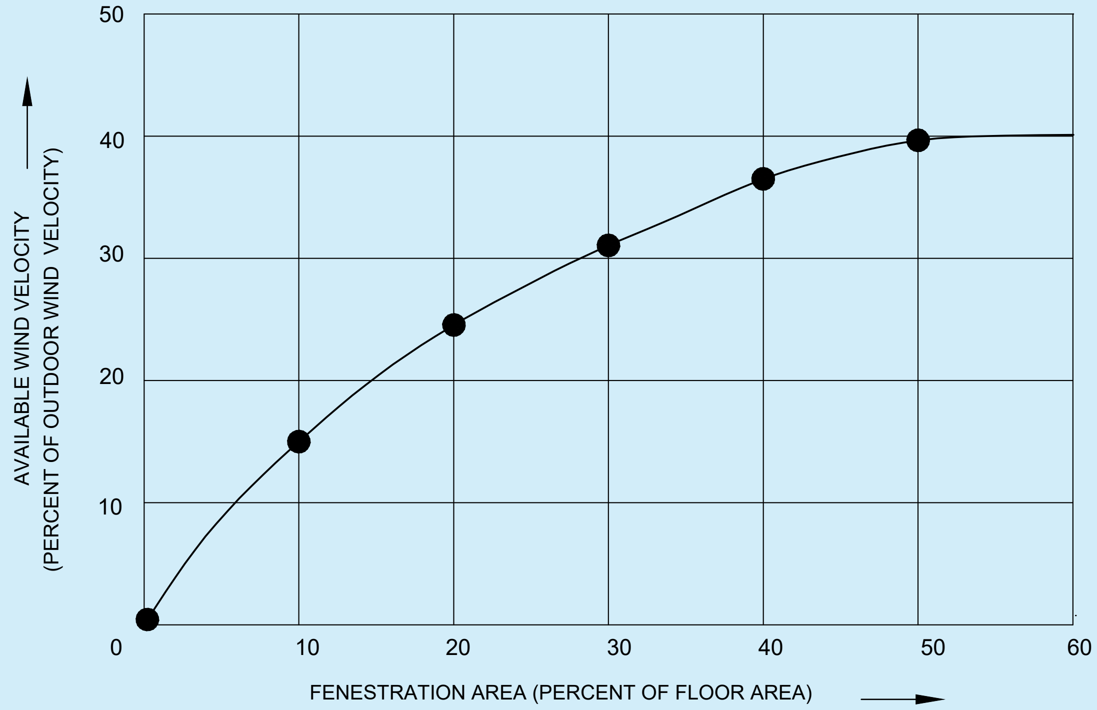

FIG. 6 EFFECT OF AREA OF OPENING ON AVERAGE INDOOR WIND VELOCITY

h) Where the direction of wind is quite constant and dependable, the size of the inlet should be kept within 30 percent to 50 percent of the total area of openings and the building should be oriented perpendicular to the incident wind. Where direction of the wind is quite variable the openings may be arranged so that as far as possible there is approximately equal area on all sides. Thus, no matter what the wind direction be, there would be some openings directly exposed to wind pressure and others to air suction and effective air movement through the building would be assured;

j) Windows of living rooms should open directly to an open space. In places where building sites are restricted, open space may have to be created in the buildings by providing adequate courtyards;

k) In the case of rooms with only one wall exposed to outside, provision of two windows on that wall is preferred to that of a single window;

m) Windows located diagonally opposite to each other with the windward window near the upstream corner give better performance than other window arrangements for most of the building orientations;

n) Horizontal louvers, that is, sunshades atop windows deflect the incident wind upward and reduce air motion in the zone of occupancy. A horizontal slot between the wall and horizontal louver prevents upward deflection of air in the interior of rooms. Provision of inverted L type (Γ) louver increases the room air motion provided that the vertical projection does not obstruct the incident wind (*see* Fig. 7);

p) Provision of horizontal sashes inclined at an angle of 45° in appropriate direction helps to promote the indoor air motion. Sashes projecting outward are more effective than projecting inward;

q) Air motion at working plane 0.4 m above the floor can be enhanced by 30 percent using a pelmet type wind deflector (*see* Fig. 8);

r) Roof overhangs help promoting air motion in the working zone inside buildings;

s) In case of room with windows on one wall, with single window, the room wind velocity inside the room on the windward side is 10 percent of outdoor velocity at points up to a distance one-sixth of room width from the window and then decreases rapidly and hardly any air movement is produced in the leeward half portion of the room. The average indoor wind velocity is generally less than 10 percent of outdoor velocity. When two windows are provided and wind impinges obliquely on them, the inside velocity increases up to 15 percent of the outdoor velocity;

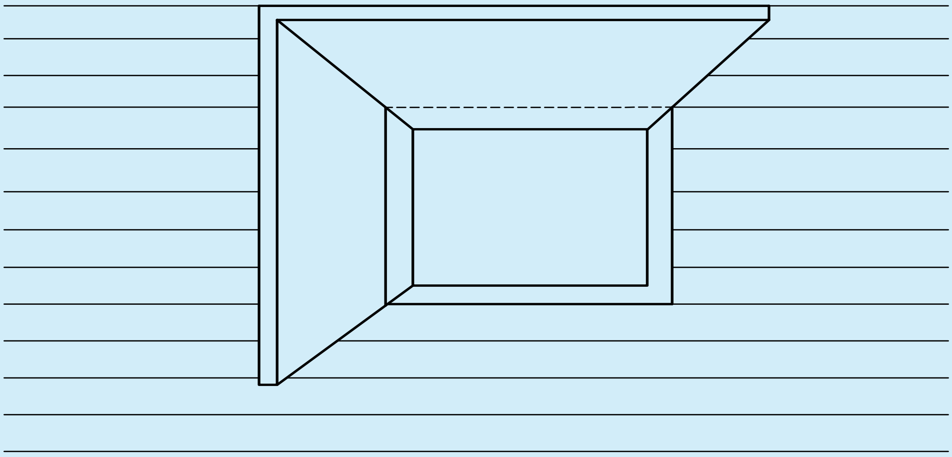

FIG. 7 L-TYPE LOUVER

$W_D = H_W / 6$
H_W - WINDOW HEIGHT
H_D - DEFLECTOR HEIGHT
W_D - DEFLECTOR WIDTH

FIG. 8 SKETCH OF A PELMET TYPE WIND DEFLECTOR

t) Cross ventilation can be obtained through one side of the building to the other, in case of narrow buildings with the width common in the multistoreyed type by the provision of large and suitably placed windows or combination of windows and wall ventilators for the inflow and outflow of air;

u) *Verandah* open on three sides is to be preferred since it causes an increase in the room air motion for most of the orientations of the building with respect to the outdoor wind;

v) A partition placed parallel to the incident wind has little influence on the pattern of the air flow, but when located perpendicular to the main flow, the same partition creates a wind shadow. Provision of a partition with spacing of 0.3 m underneath helps augmenting air motion near floor level in the leeward compartment of wide span buildings;

w) Air motion in a building unit having windows tangential to the incident wind is accelerated when another unit is located at end-on position on downstream side (*see* Fig. 9);

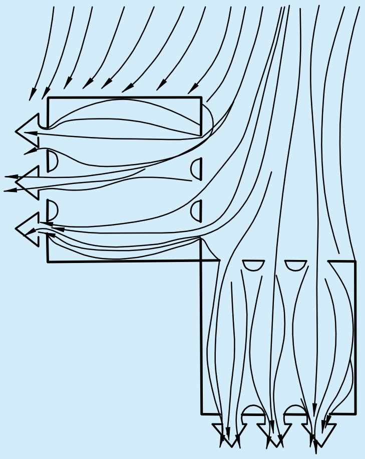

FIG. 9 TWO UNITS LOCATED AT THE END-ON POSITION

y) Air motion in two wings oriented parallel to the prevailing breeze is promoted by connecting them with a block on downstream side;

z) Air motion in a building is not affected by constructing another building of equal or smaller height on the leeward side; but it is slightly reduced if the leeward building is taller than the windward block;

aa) Air motion in a shielded building is less than that in an unobstructed building. To minimize shielding effect, the distances between two rows should be 8 H for semi-detached houses and 10 H for long rows houses. However, for smaller spacing the shielding effect is also diminished by raising the height of the shielded building;

bb) Hedges and shrubs deflect the air away from the inlet openings and cause a reduction in indoor air motion. These elements should not be planted at a distance of about 8 m from the building because the induced air motion is reduced to minimum in that case. However, air motion in the leeward part of the building can be enhanced by planting a low hedge at a distance of 2 m from the building;

cc) Trees with large foliage mass having trunk bare of branches up to the top level of window, deflect the outdoor wind downwards and promotes air motion in the leeward portion of buildings;

dd) Ventilation conditions indoors can be ameliorated by constructing buildings on earth mound having a slant surface with a slope of 10° on upstream side;

ee) In case of industrial buildings, the window height should be about 1.6 m and width about two-third of wall width. These should be located at a height of 1.1 m above the floor. In addition to this, openings around 0.9 m high should be provided over two-third length of the glazed area in the roof lights;

ff) Height of industrial buildings, although determined by the requirements of industrial processes involved, are generally kept large enough to protect the workers against hot stagnant air below the ceiling as also to dilute the concentration of contaminant inside. However, if high level openings in roof or walls are provided, building height can be reduced to 4 m without in any way impairing the ventilation performance; and

gg) The maximum width up to which buildings of height usually found in factories, being effectively ventilated by natural means by wind action, is 30 m, beyond which sufficient reliance cannot be placed on prevailing winds. Approximately half the ventilating area of openings should be between floor level and a height of 2.25 m from the floor.

NOTE — For data on outdoor wind speeds at a place, reference may be made to 'The Climatic Data Handbook prepared by Central Building Research Institute, Roorkee, 1999'.

5.4.3.2 *By stack effect*

Natural ventilation by stack effect occurs when air inside a building is at a different temperature than air outside. Thus, in heated buildings or in buildings wherein hot processes are carried on and in ordinary buildings during summer nights and during pre-monsoon periods, the inside temperature is higher than that of outside, cool outside air will tend to enter through openings at low level and warm air will tend to leave through openings at high level. It would, therefore, be advantageous to provide ventilators as close to ceilings as possible. Ventilators can also be provided in roofs as, for example, cowl, vent pipe, covered roof and ridge vent.

5.4.4 *Design Charts for Natural Ventilation*

Openings for natural ventilation can be sized without the need for complex and expensive computer simulation methods using analytical techniques. The design charts (DCs) provided hereunder can be used to assist in the sizing of ventilation openings to deliver natural ventilation.

The design charts are derived from analytical techniques. They provide either the geometrical free area (A_f) of openings to deliver a recommended air flow rate, or the achieved flow rate for a given free area.

Based on information for inside-outside air temperature difference (ΔT), wind speed (U) and wind pressure co-efficient (ΔC_p), the DCs are applicable for a wide range of weather conditions and parameters appropriate for residential buildings located in the selected Indian climatic zones.

These are considered to be the most common configurations encountered in practice in Indian residences. The corresponding DCs are:

a) DC-01 — Buoyancy-driven flow; single-sided ventilation with one opening (Fig. 10A and Fig. 11);

b) DC-02 — Buoyancy-driven flow; cross-ventilation with multiple openings (Fig. 10B and Fig. 12);

c) DC-03 — Wind-driven flow; single-sided ventilation with one opening (Fig. 10C and Fig. 13); and

d) DC-04 — Wind-driven flow; cross-ventilation with multiple openings (Fig. 10D and Fig. 14).

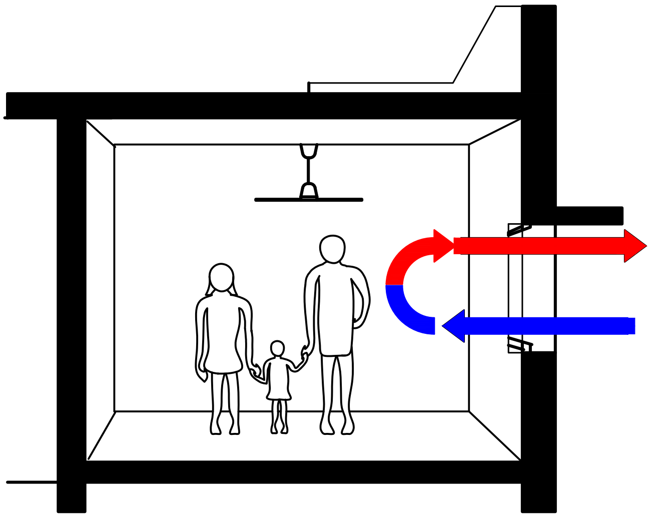

FIG. 10A DC-01

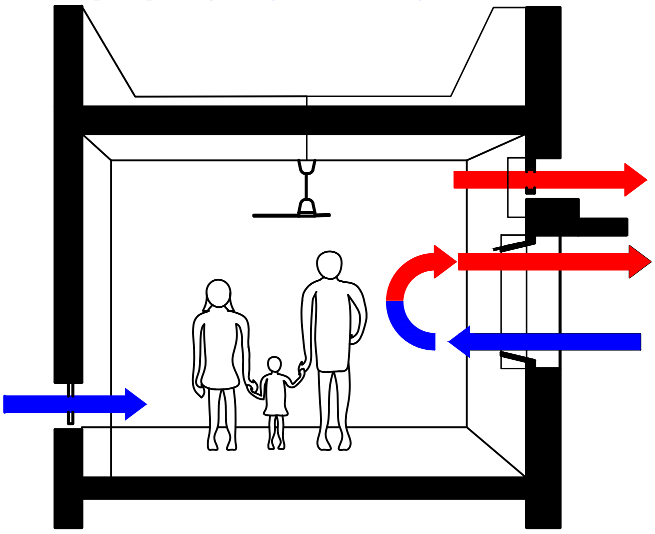

FIG. 10B DC-02

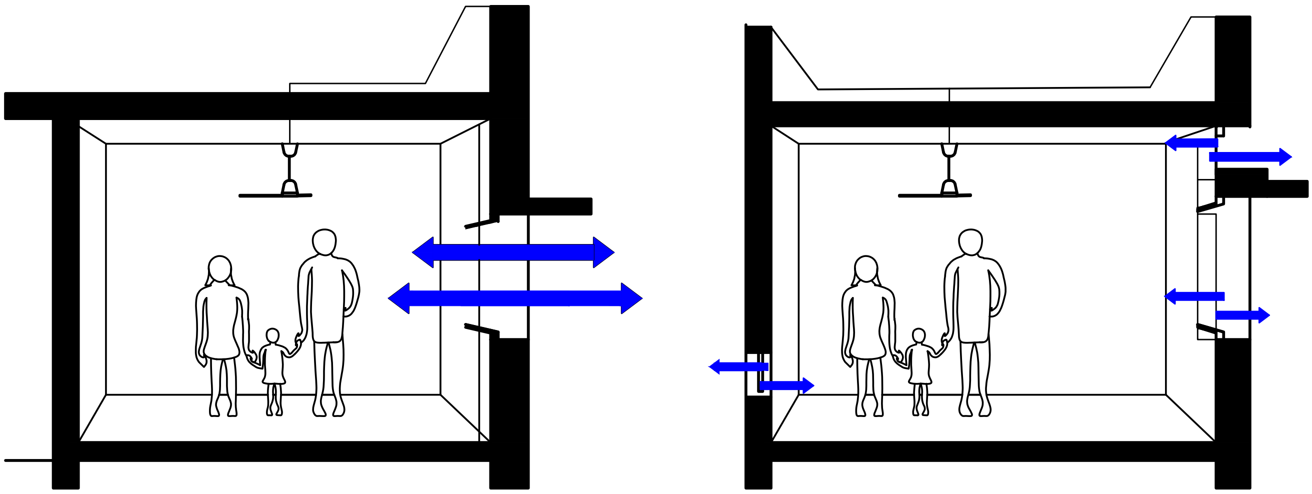

FIG. 10C DC-03 FIG. 10D DC-04

FIG. 10 CROSS-SECTION SKETCHES OF THE DRIVING FORCES FOR THE NATURAL VENTILATION SYSTEMS PRESENTED IN THE FOUR DESIGN CHARTS

5.4.4.1 *Design charts for natural ventilation — by stack effect*

a) DC-01 — Buoyancy-driven flow; single-sided ventilation with one opening;

The DC-01 is derived from the equation below (*see also* Fig. 11). For single opening, the value for C_d adopted is 0.25:

$$A_f = \frac{q_{rec}}{C_d}\sqrt{\frac{(T_{inside}+273)}{g\,h_a\Delta T_{inside\text{-}outside}}}$$ (*see also* **C-1.2.1**)

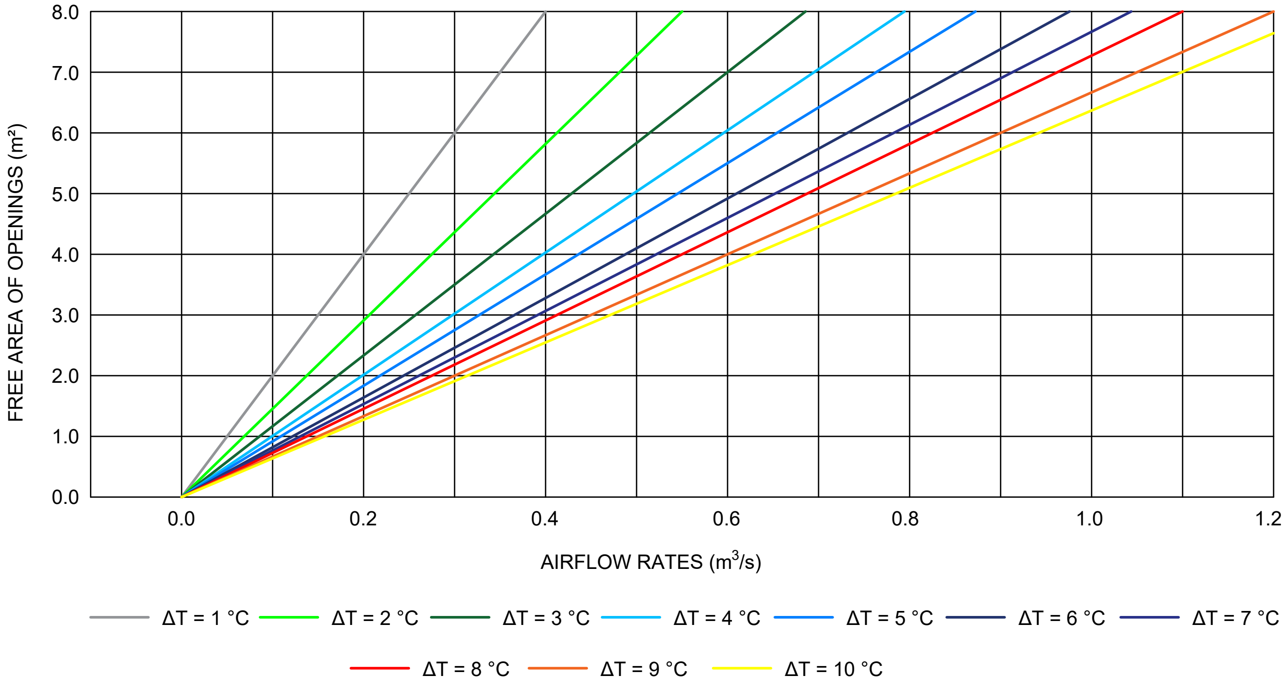

FIG. 11 DESIGN CHART DC-01 FOR SINGLE-SIDED SINGLE OPENING BUOYANCY DRIVEN FLOW

b) DC-02 — buoyancy-driven flow; cross-ventilation;

The DC-02 is also derived from the equation below (*see also* Fig. 12). Conversely, for multiple openings, the value for C_d adopted is 0.61:

$$V_z = V_{ref}\ k\ z^{\alpha}(m/s)$$ (*see also* **C-1.2.3.1**)

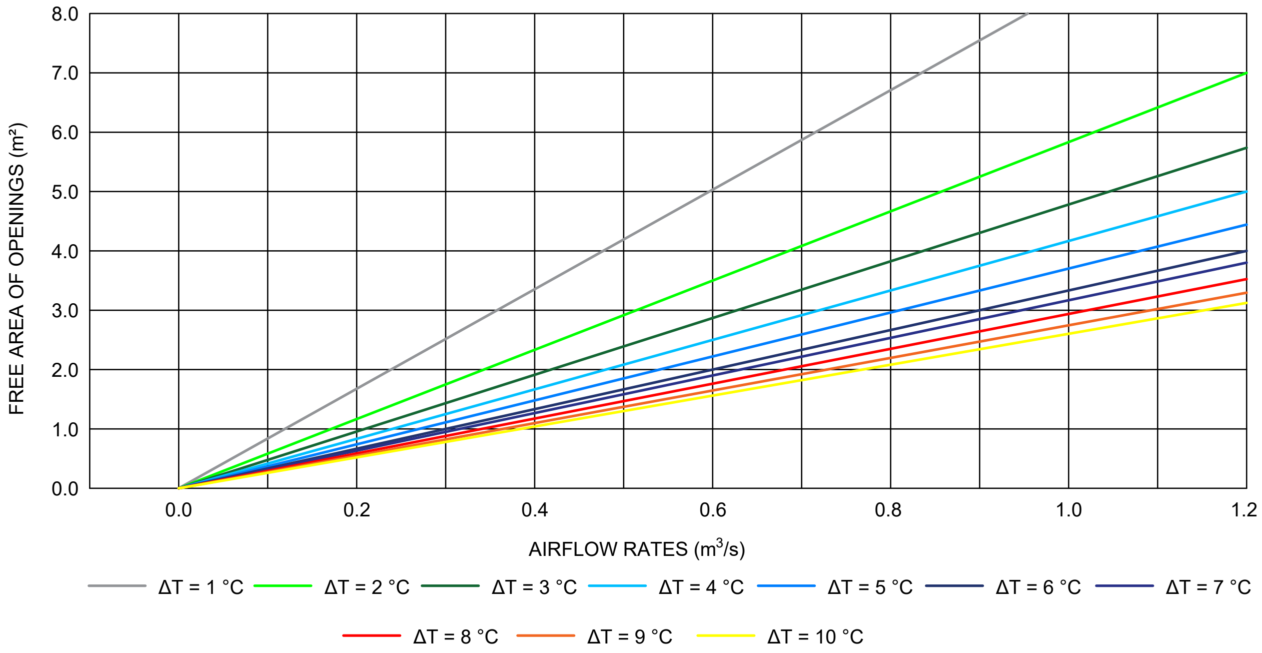

FIG. 12 DESIGN CHART DC-02 FOR MULTIPLE OPENINGS AND BUOYANCY-DRIVEN FLOW

5.4.4.2 *Design charts for natural ventilation — by wind effect*

a) DC-03 — Wind-driven flow; single-sided ventilation with one opening;

The DC-03 is derived from the following equation (*see also* Fig. 13):

$$A_f = {}^{q_{rec}}/_{C\,V_z}$$ (*see also* **C-1.2.3**)

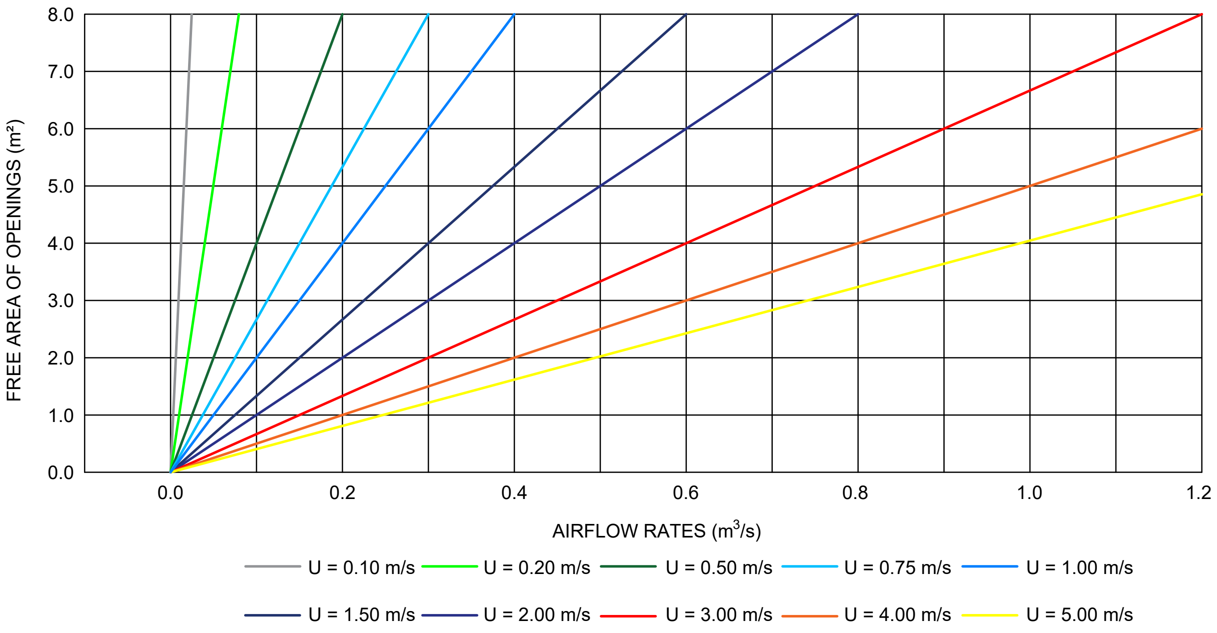

FIG. 13 DESIGN CHART DC-03 FOR SINGLE-SIDED SINGLE OPENINGS AND WIND-DRIVEN FLOW

b) DC-04 — Wind-driven flow; cross-ventilation with multiple openings;

The DC-04 is derived from the following equation (*see also* Fig. 14):

$$A_f = q_{ref}\left(C_d V_z \sqrt{\frac{\Delta C_p}{2}}\right)^{-1}$$ (*see also* **C-1.2.4**)

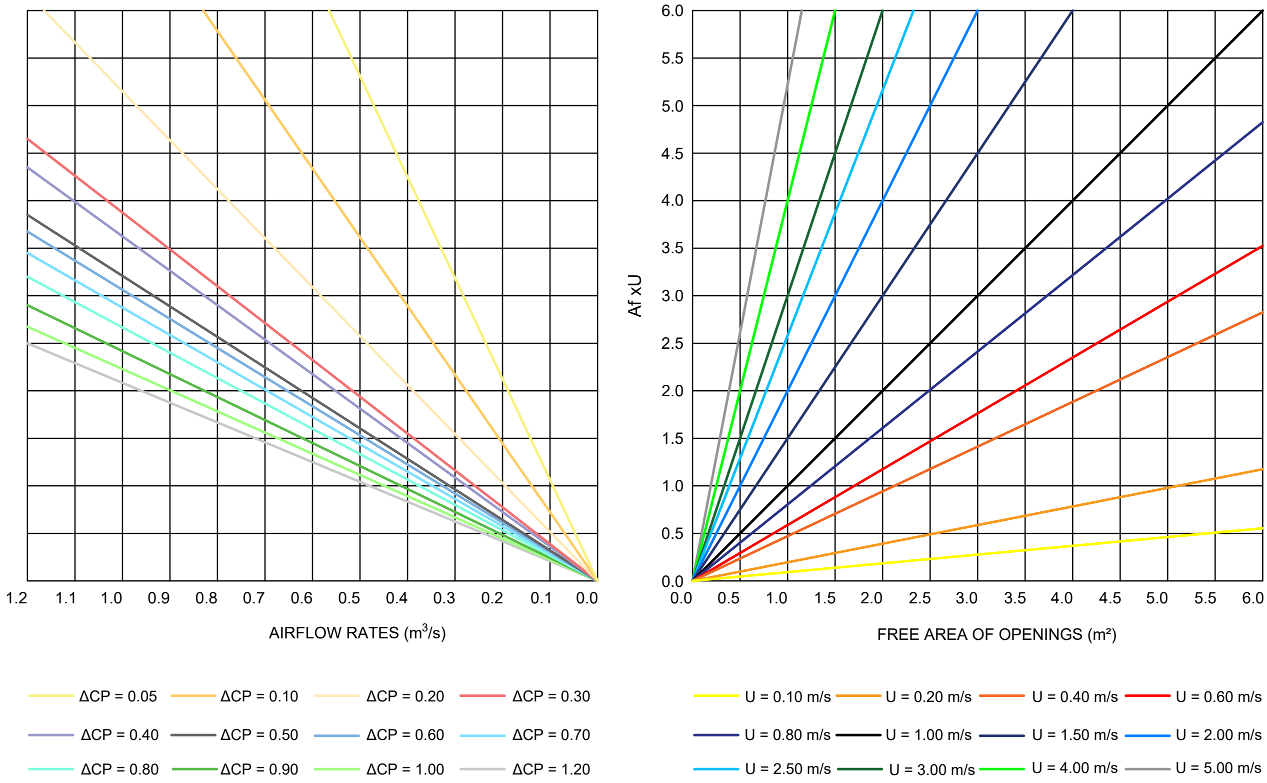

FIG. 14 DESIGN CHART DC-04 FOR MULTIPLE OPENINGS AND WIND-DRIVEN FLOW

5.4.4.3 For detailed application and use of the design charts for natural ventilation, reference may be made to Annex C.

5.5 Mechanical Ventilation

The requirements of mechanical ventilation should be in accordance with Part D ‘Building Services, Section 3 Air Conditioning, Heating and Mechanical Ventilation’ of this NBCS.

5.6 Determining Rate of Ventilation

5.6.1 *Natural Ventilation*

This is difficult to measure as it varies from time to time. The amount of outside air through windows and other openings depends on the direction and velocity of wind outside (wind action) and/or convection effects arising from temperature or vapour pressure differences (or both) between inside and outside of the building (stack effect).

5.6.1.1 *Wind action*

For determining the rate of ventilation based on wind action the wind may be assumed to come from any direction within 45° of the direction of prevailing wind. Ventilation due to external wind is given by the following formula:

$$Q_w = K \times A \times V$$

where

Q_w = rate of air flow, in m^3/h;

K = coefficient of effectiveness, which may be taken as 0.6 for wind perpendicular to openings and 0.3 for wind at an angle less than 45° to the openings;

A = free area of inlet openings, in m^2; and

V = wind speed, in m/h.

NOTE — For wind data at a place, the local Meteorological Department may be consulted.

5.6.1.2 *Stack effect* (*thermal action*)

Ventilation due to convection effects arising from temperature difference between inside and outside is given by:

$$Q_T = 7.0\,A\sqrt{h\,(t_r - t_o)}$$

where

Q_T = rate of air flow, in m^3/h;

A = free area of inlet openings, in m^2;

h = vertical distance between inlets and outlets, in m;

t_r = average temperature of indoor air at height h, in °C; and

t_o = temperature of outdoor air, in °C.

NOTE — The equation is based on 0.65 times the effectiveness of openings. This should be reduced to 0.50 if conditions are not favourable.

5.6.1.3 When areas of inlet and outlet openings are unequal, the value of A may be calculated using the equation:

$$\frac{2}{A^2} = \frac{1}{A^2_{\text{inlet}}} + \frac{1}{A^2_{\text{outlet}}}$$

5.6.1.4 *Combined effect of wind and thermal action*

When both forces (wind and thermal) act together in the same direction, even without interference, the resulting air flow is not equal to the two flows estimated separately.

When acting simultaneously, the rate of air flow through the building may be computed by the following equation:

$$Q^2 = {Q_w}^2 + {Q_t}^2$$

where

Q = resultant volume of air flow, in m^3/min;

Q_w = volume of air flow due to wind force, in m^3/min; and

Q_t = volume of air flow due to thermal force, in m^3/min.

Wind velocity and direction, outdoor temperature, and indoor distribution cannot be predicted with certainty, and refinement in calculation is not justified. A simple method is to calculate the sum of the flows produced by each force separately. Then using the ratio of the flow produced by thermal forces to the aforementioned sum, the actual flow due to the combined forces can be approximated from Fig. 15. When the two flows are equal, the actual flow is about 30 percent greater than the flow caused by either force acting independently (*see* Fig. 15).

Judgment is necessary for proper location of openings in a building specially in the roof, where heat, smoke and fumes are to be removed. Usually, windward monitor openings should be closed, but if wind is so slight that temperature head can overcome it, all openings may be opened.

5.6.1.5 For method for determining the rate of ventilation based on probable indoor wind speed with typical illustrative example for residential building, reference may be made to **A-4** of good practice [D-1(9)].

5.6.2 *Mechanical Ventilation*

The determination of rate of ventilation in case of mechanical ventilation shall be done in accordance with Part D 'Building Services, Section 3 Air Conditioning, Heating and Mechanical Ventilation' of this NBCS.

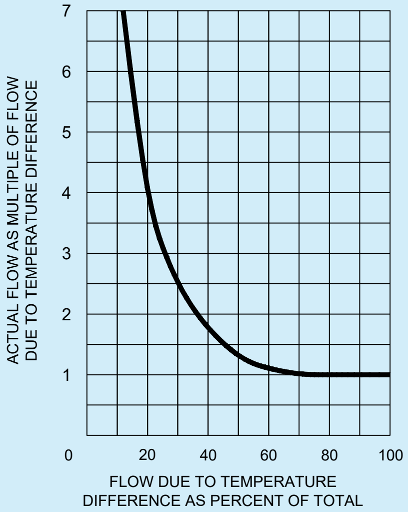

FIG. 15 DETERMINATION OF FLOW CAUSED BY COMBINED FORCES OF WIND AND TEMPERATURE DIFFERENCE

5.6.3 *Combined effect of Different Methods of Ventilation*

When combination of two or more methods of general ventilation is used, the total rate of ventilation shall be reckoned as the highest of the following three, and this rule shall be followed until an exact formula is established by research:

a) 1.25 times the rate of natural ventilation;

b) Rate of positive ventilation; and

c) Rate of exhaust of air.

5.6.4 *Measurement of Air Movement*

The rate of air movement of turbulent type at the working zone shall be measured either with a Kata thermometer (dry silvered type) or heated thermometer or properly calibrated thermocouple anemometer. Whereas anemometer gives the air velocity directly, the Kata thermometer and heated thermometer give cooling power of air and the rate of air movement is found by reference to a suitable nomogram using the ambient temperature.

5.7 Energy Conservation in Ventilation System

5.7.1 Maximum possible use should be made of wind induced natural ventilation. This may be accomplished by following the design guidelines given in 5.7.1.1.

5.7.1.1 Adequate number of circulating fans should be installed to serve all interior working areas during summer months in the hot dry and warm humid regions to provide necessary air movement at times when ventilation due to wind action alone does not afford sufficient relief.

5.7.1.1.1 The capacity of a ceiling fan to meet the requirement of a room with the longer dimension *D* metre should be about 55 D m^3/min.

5.7.1.1.2 The height of fan blades above the floor should be $(3H + W)/4$, where H is the height of the room and W is the height of work plane.

5.7.1.1.3 The minimum distance between fan blades and the ceiling should be about 0.3 m.

5.7.2 Electronic regulators should be used instead of resistance type regulators for controlling the speed of fans.

5.7.3 When actual ventilated zone does not cover the entire room area, then optimum size of ceiling fan should be chosen based on the actual usable area of room, rather than the total floor area of the room. Thus, smaller size of fan can be employed and energy saving could be achieved.

5.7.4 Power consumption by larger fans is obviously higher, but their power consumption per square metre of floor area is less and service value higher. Evidently, improper use of fans irrespective of the rooms' dimensions is likely to result in higher power consumption. From the point of view of energy consumption, the number of fans and the optimum sizes for rooms of different dimensions are given in Table 17.

Table 17 Optimum Size and Number of Fans for Rooms of Different Sizes

5.7.5 *Acceptable Air Temperature with the Increase in the Air Speed*

The natural ventilation (NV) – mixed mode (MM) solutions combine designed openings for natural ventilation with the simultaneous use of mechanical ceiling fans to deliver thermal comfort with minimal use of energy. The air movement induced by the fan allows a rise in the acceptable operative temperature which is proportional to the increase in the air speed. This combination will be referred to as NV-MM solutions for 'enhanced natural ventilation (NV+).

The total number of hours of the year for which the outdoor conditions are feasible for natural ventilation, calculated as per the adaptive thermal comfort model for India-mixed mode building, and estimated with the NV-MM solutions for NV+, are shown in Fig. 16 for each of the eight Indian cities. This estimation utilizes the values for the corresponding rise in the acceptable air temperature with the increase in the air speed shown in Table 18 for the scenario with $T_{\text{radiant}} = T_{\text{air}}$ (as in specialist literature) and applies to clothing insulation values (in clo) ranging from 0.50 clo to 0.70 clo and to metabolic rates (in met) ranging from 1.00 met ranging from 0.50 clo to 0.70 clo and to metabolic rates (in met) ranging from 1.00 met to 1.30 met.

NOTE — Specialist literature may be ASHRAE 2010.

This scenario is considered likely to occur in a typical residential environment during daytime and in summer season, with NV operating and without any mechanical cooling source (a radiant cooling panel). This scenario yields more conservative values than the scenario when occupants have some control over the local environment (as per specialist literature).

NOTE — Specialist literature may be ASHRAE 2017.

v)	IV	1.5	2.50	3.60	4.00

5.7.6 *Mixed-Mode Principles*

Buildings that are designed with a mixed-mode ventilation strategy rely on natural ventilation for much of the occupied hours but also have integrated mechanical ventilation and cooling systems that are used in certain climatic or internal heat gain conditions. Mixed-Mode (MM) systems include naturally ventilated buildings that are designed using one of the following approaches:

a) Concurrent mixed-mode (*see* Fig. 17A) — Where both systems operate at the same space at the same time. The mechanical system operates as supplementary ventilation or cooling while the occupants are free to operate the windows based on their personal preference. This strategy is the most common form of mixed mode ventilation strategy typically employed for open-plan offices and residential buildings;

b) Change-over mixed-mode (*see* Fig. 17B and Fig. 17C) — Where the mechanical systems and natural ventilation operate in the same space at different times of the day or year. This approach requires an automated control system to determine which mode should be used at a particular point in time. The selection is based on a variety of input parameters such as outdoor conditions and occupancy. The system operating as change-over MM in a residence can either run automatically or inform the occupants to open or close the windows and switch on/off HVAC systems; and

c) Zoned mixed-mode (*see* Fig. 17D) — Where the mechanical cooling and natural ventilation operate at the same time but in different spaces of the building. This ventilation strategy is suitable for large office buildings where some offices could use natural ventilation by operating the windows whereas other rooms such as conference rooms may require a mechanical system for fresh air distribution.

Mixed-mode ventilation presents an energy efficient alternative to full air conditioning by capitalizing on the potential for natural ventilation when conditions permit.

METHOD OF CALCULATING SOLAR LOAD ON VERTICAL SURFACES OF DIFFERENT ORIENTATION

A-1 DETAILS OF CALCULATION

A-1.1 The solar energy above the earth's atmosphere is constant and the amount incident on unit area normal to sun's rays is called solar constant (1.360 8 kWm^{-2} or 2 cal/cm^2/min). This energy, in reaching the earth's surface, is depleted in, the atmosphere due to scattering by air molecules, water vapour, dust particles, and absorption by water vapour and ozone. The depletion varies with varying atmospheric conditions. Another important cause of depletion is the length of path traversed by sun's rays through the atmosphere. This path is the shortest when sun is at the zenith and, as the altitude of the sun decreases, the length of path in the atmosphere increases. Fig. 18 gives the computed incident solar energy/hour on unit surface area normal to the rays under standard atmospheric conditions (*see* Note below) for different altitudes of the sun.

NOTE — The standard atmospheric conditions assumed for this computation are: cloud-free, 300 dust particles per cm^3, 15 mm of precipitable water, 2.5 mm of ozone, at sea level.

A-1.2 In order to calculate the solar energy on any surface other than normal to the rays, the altitude of the sun at that time should be known. The corresponding value of direct solar radiation (I_N) should then be found with the help of Fig. 19. The solar radiation incident on any surface (I_S) is given by:

$$I_S = I_N \left(\sin\beta \sin\phi + \cos\beta \cos\alpha \cos\phi\right)$$

where

β = solar altitude;

ϕ = angle tilt of the surface from the vertical (*see* Fig. 19); and

α = wall solar azimuth angle.

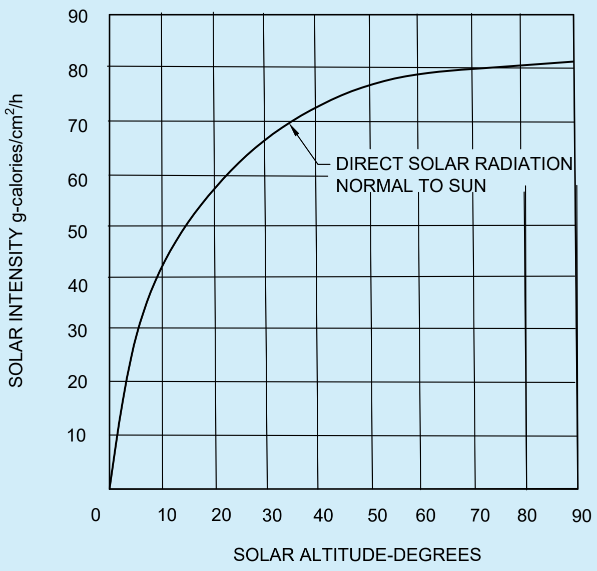

FIG. 18 DIRECT SOLAR INTENSITIES NORMAL TO SUN AT SEA LEVEL FOR STANDARD CONDITION (COMPUTED)

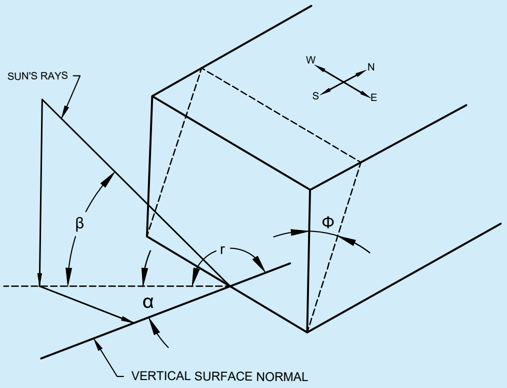

FIG. 19 DEFINITION OF SOLAR ANGLES

A-2 EXAMPLE TO FIND OUT ORIENTATION ON THE BASIS OF SOLAR LOAD

A-2.1 Example

A-2.1.1 As an example, a simple building with flat roof, 10 m × 20 m and 4 m high is dealt with below. For the sake of generalization, no shading device or verandah is taken.

A-2.1.2 As the roof is horizontal, it will receive the same solar heat in any orientation.

A-2.1.3 The area of the vertical surfaces are 4 m × 10 m = A (say) and 4 m × 20 m = $2A$. Since, the external wall surfaces are not in shade except when the sun is not shining on them, the total solar load in a day on a surface can be obtained by multiplying the total load per unit area per day (*see* Table 3) by the area of the surface. For four principal orientations of the building, the total solar load on the building is worked out in Table 19.

A-2.1.4 From Table 19, it can be seen that for the above type of building, orientation 3 (longer surface facing North and South) is appropriate as it affords maximum solar heat gain in winter and in summer. This is true for all places of India from the point of solar heat gain. By further increasing the length to breadth ratio, the advantage of this orientation will be more pronounced. It may also be noted that in higher altitudes, the relative merit of this orientation is more.

A-2.1.5 It is also seen that the total solar heat on the building is the same for orientation 2 and 4. But if the site considerations require a choice between these two, orientation 2 should be preferred at places north of latitude 23° N and orientation 4 at southern places. This is so because the total solar load per unit area in summer on the north western wall decreases with the increase in latitude and that on the south western wall increases. It would, therefore, be advantageous to face only smaller surface of the building to greater solar load in the summer afternoons, when the air temperature also is higher.

A-2.1.6 At hill stations, winter season cause more discomfort and so sole criterion for optimum orientation should be based on receiving maximum solar energy on building in winter.

Table 19 Solar Heat Gained Due to Orientation of Buildings

SKY COMPONENT TABLES

B-1 DESCRIPTION OF TABLES

B-1.1 The three sky component tables are as given below:

a) Table 20 — Percentage sky components on the horizontal plane due to a vertical rectangular opening for the clear design sky;

b) Table 21 — Percentage sky components on the vertical plane perpendicular to a vertical rectangular opening for the clear design sky; and

c) Table 22 — Percentage sky components on the vertical plane parallel to a vertical rectangular opening for the clear design sky.

B-1.2 All the Table 20, Table 21 and Table 22 are for an unglazed opening illuminated by the clear design sky.

B-1.3 The values tabulated are the components at a point *P* distant from the opening on a line perpendicular to the plane of the opening through one of its lower corners, and *l* and *h* are the width and height respectively of the rectangular opening (*see* Fig. 20).

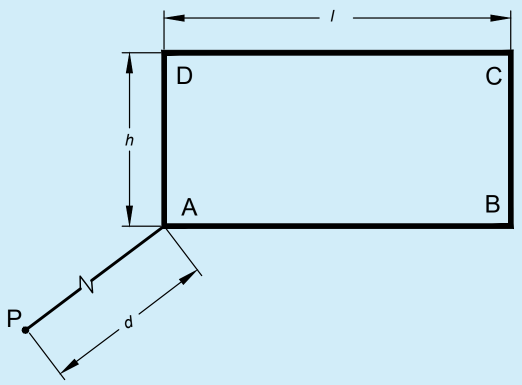

FIG. 20 DEPICTION OF OBSERVATIN POINT ' P '

B-1.4 Sky component for different *h*/*d* and *l*/*d* values are tabulated, that is, for windows of different size and for different distances of the point *P* from the window.

B-1.5 By suitable combination of the values obtained from the Table 20, Table 21 and Table 22, for a given point for a given window, the sky component in any plane passing through the point may be obtained.

B-1.6 Method of Using the Tables

B-1.6.1 Method of using the Table 20, Table 21 and Table 22 to get the sky component at given point is explained with help of the following example.

B-1.6.2 *Example*

It is desired to calculate the sky component (F) due to a vertical window ABCD with width 1.8 m and height 1.5 m at a point P on a horizontal plane 3.0 m from the window wall located as shown in the Fig. 21. Foot of the perpendicular N is 0.6 m below the sill and 0.9 m to the left of AD.

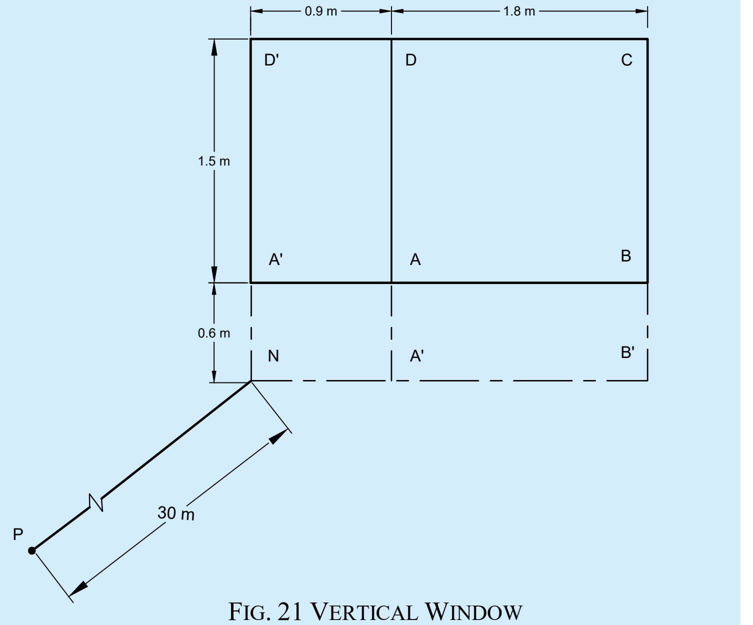

FIG. 21 VERTICAL WINDOW

Consider ABCD extended to NB'CD'

a) For NB'CD'

$l/d = (1.8 + 0.9)/3 = 0.9$

$h/d = (1.5 + 0.6)/3 = 0.7$

$F_1 = 5.708$ percent (from Table 20)

b) For NA'DD'

$l/d = 0.9/3 = 0.3$

$h/d = (1.5 + 0.6)/3 = 0.7$

$F_2 = 2.441$ percent (from Table 20)

c) For NB'BA'

$l/d = (1.8 + 0.9)/3 = 0.9$

$h/d = 0.6/3 = 0.2$

$F_3 = 0.878$ percent (from Table 20)

d) For NA'AA'

$l/d = 0.9/3 = 0.3$

$h/d = 0.6/3 = 0.2$

F_4 = 0.40 3 percent (from Table 20)

Since ABCD = NB’CD’ – NA’DD’ – NB’BA’ + NA’AA’

Sky component, F = $F_1 - F_2 - F_3 + F_4$
= 5.708 – 2.441 – 0.878 + 0.403
= 2.792

B-2 GENERAL INSTRUCTIONS

B-2.1 For irregular obstructions like row of trees parallel to the plane of the window, equivalent straight boundaries horizontal and vertical, maybe drawn.

B-2.2 Waldram diagrams are an effective early-stage design tool for planning daylight and direct solar illuminance for extremely irregular obstructions or obstructions not in a plane parallel to the window. Fig. 22 and Fig. 23 show two possible massing schemes for a site located at 17° N latitude, while Fig. 24 and Fig. 25 illustrate the corresponding Waldram diagrams drawn from the central open area of the site. The white area above the shadow silhouettes in Fig. 24 and Fig. 25 indicate unobstructed sky (48 percent sky view in case of Fig. 24 and 65 percent sky view in case of Fig. 25). The yellow lines in Fig. 24 and Fig. 25 indicate the annual sun path as seen from the middle of the central open area of the site, aiding in evaluating sky visibility and optimizing site layouts for improved daylight performance.

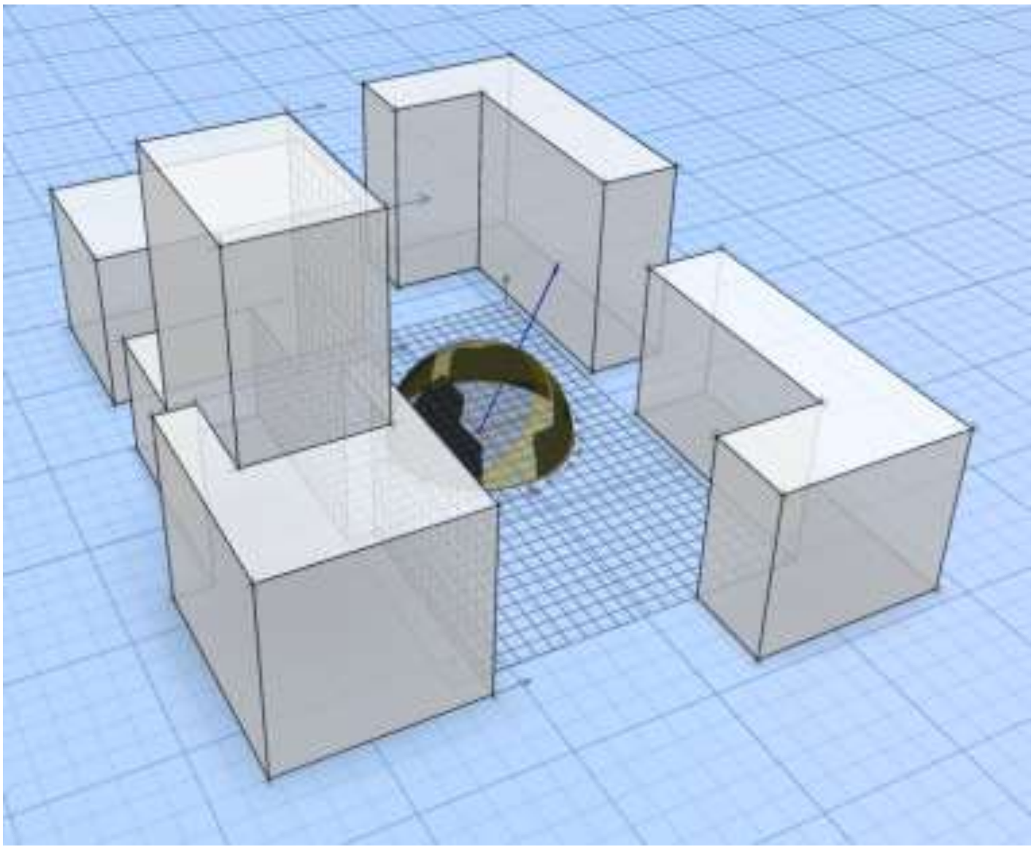

FIG. 22 MASSING SCHEME A

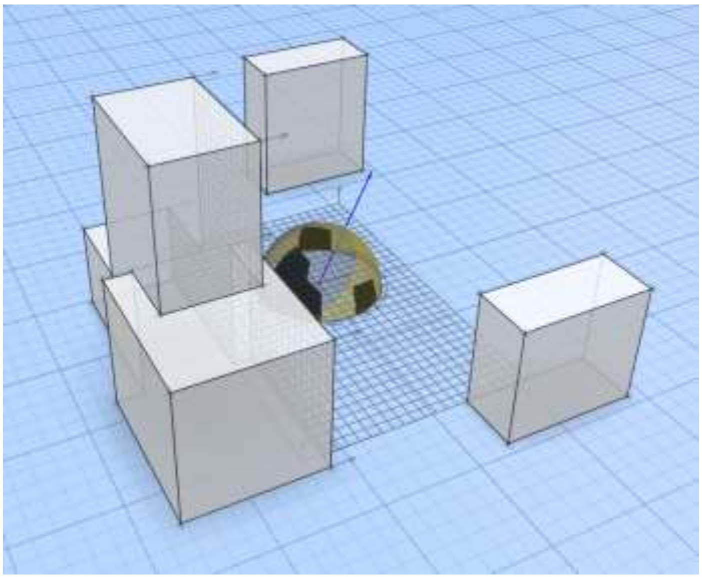

FIG. 23 MASSING SCHEME B

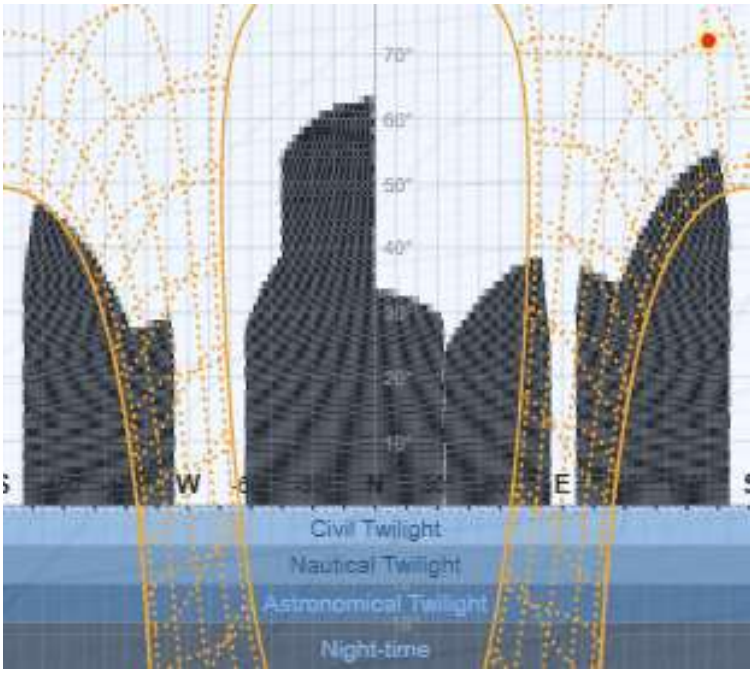

FIG. 24 WALDRAM DIAGRAM A

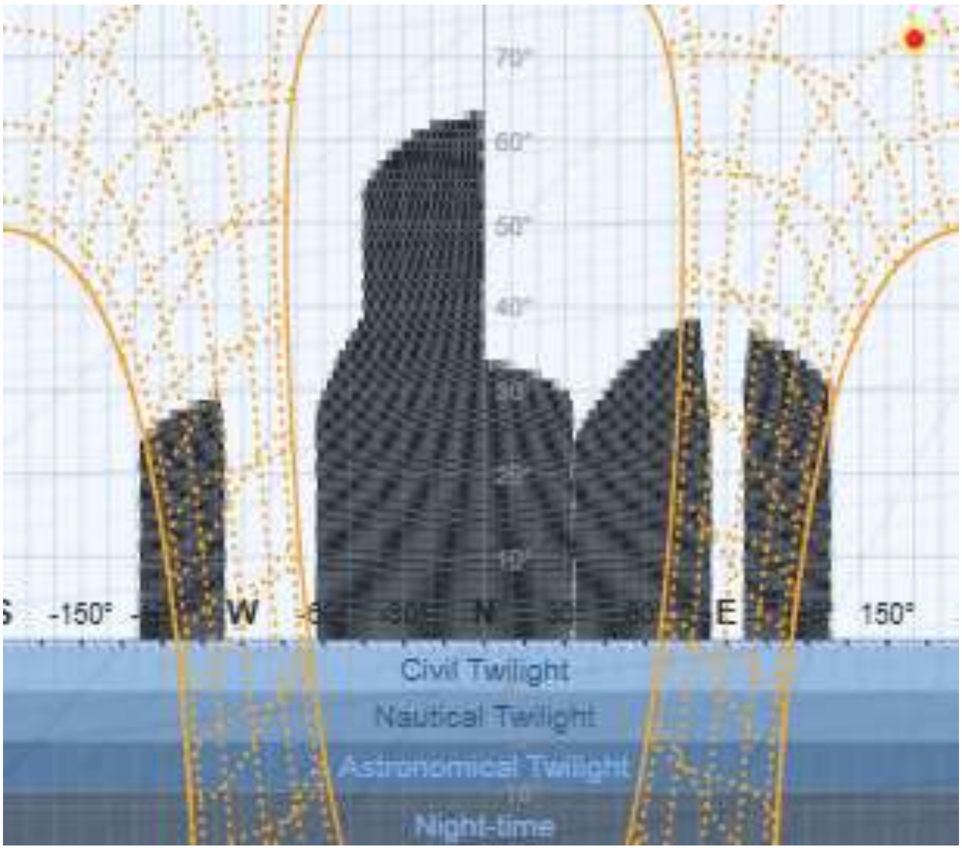

FIG. 25 WALDRAM DIAGRAM B

B-2.3 For bay windows, dormer windows or corner windows the effective dimensions of window opening computed should be taken when using the Table 20, Table 21 and Table 22 to find the sky components.

B-3 CALCULATION OF INTERNAL REFLECTED COMPONENT

B-3.1 The internal reflected component (IRC) is a variable quantity which varies from point to point in a room depending upon the interior finish. IRC value is maximum at the centre of the room and decreases elsewhere in all directions. For processing calculations of IRC at any given point of the room, special techniques have to be made out. The internal reflected component may be calculated by using the formula:

$$IRC = \frac{0.85W}{A(1\text{-R})} \left(CR_{\text{fw}} + 10R_{\text{cw}}\right)$$

where

W = window area;

C = constant of value 78 when there is no external obstruction but it has different values as shown in the following table when there are obstructions;

R_{fw} = average reflection factor of the floor and those parts of the wall below the plane of the mid-height of the window (excluding the window wall);

R_{cw} = average reflection factor of the ceiling and those parts of the wall above the plane of the mid-height of the window (excluding the window wall);

A = area of all the surfaces in the room (ceiling walls, floor and windows); and

R = average reflection factor of all surfaces in the room (ceiling, walls, floor and windows) expressed as a decimal part of unity.

Sl No. (1)	*Angle of Obstruction* Degree (2)	*Sky + External Obstruction* C (3)
i)	5	68.9
ii)	15	50.6
iii)	25	36.2
iv)	35	26.7
v)	45	20.1
vi)	55	15.8
vii)	65	12.9
viii)	75	11.1
ix)	85	10.36

B-3.2 Example

Consider two rooms of dimensions:

Room X = 6 m (l) × 5 m (w) × 3 m (ht)

Room Y = 3.7 m × 3 m × 3 m

Let the window area be 15 percent of the floor area and be glazed.

Window size in room X = 2.5 m × 1.8 m

Window size in room Y = 3.7 m × 3 m

The windows are on the 6 m × 3 m side in room X and 3.7 m × 3 m side in room Y, and the sill heights are 0.9 m from floor level.

Reflection coefficients of:

walls and ceiling = 70 percent
floor = 20 percent
glazing = 15 percent

a) Value of IRC in room X:

1) Total interior area, $A = 2\,(30 + 18 + 15) = 126\ \text{m}^2$;

2) Average reflection factor of interior:

$$R = \frac{(61.5 \times 0.7) + (30 \times 0.7) + (30 \times 0.2) + (4.5 \times 0.15)}{(61.5 + 30 + 30 + 4.5)} = 0.56$$

3) $1 - R = 0.44$;

4) Mid-height of window is 1.83 m from floor, average reflection factor of room below 1.83 m level excluding the wall containing the window:

$$R_{\text{fw}} = \frac{(29.28 \times 0.7) + (30 \times 0.2)}{(29.28 + 30)} = 0.45$$

5) Average reflection factor of room above 1.83 m level excluding the wall containing the window:

$$R_{\mathrm{cw}} = \frac{(18.72 \times 0.7) + (30 \times 0.7)}{(18.72 + 30)} = 0.7$$

6) IRC = $\frac{0.85 \times 4.5}{126 \times 0.44}$ [(78 × 0.45) + (10 × 0.7)] = 2.904.

b) Value of IRC in room Y:

1) Total interior area:

$$A = 2[(3.7 \times 3) + (3.7 \times 3) + (3 \times 3)] = 62.4 \text{ m}^2$$

2) Average reflection factor:

$$R = \frac{(38 \times 55 \times 0.7 \times 3 \times 0.7) + (3.7\times 3 \times 0.2) + (1.5 \times 1.1 \times 0.15)}{(38.55 + 11.1 + 11.1 + 1.65)} = 0.596$$

3) Mid-height of window from floor = 1.46 m;

4) Average reflection factor below 1.46 m level:

$$R_{\mathrm{fw}} = \frac{(3.7 \times 3 \times 0.7) + (1.54 \times 9.7 \times 0.7)}{(11.1 + 14.94)} = 0.48$$

5) Average reflection factor above 1.46 m level:

$$R_{\mathrm{cw}} = \frac{(3.7 \times 3 \times 0.7) + (1.54 \times 9.7 \times 0.7)}{(11.1 + 14.94)} = 0.7$$

6) IRC = $\frac{0.85 \times 1.65}{62.4 \times 0.404}$ [(78 × 0.48) +(10 × 0.7)] = 2.472.

B-4 GENERAL NOTE ON DAYLIGHTING OF BUILDING

B-4.1 The main aim of day lighting design is how to admit enough light for good visibility without setting up uncomfortable glare. No simple solution may be given as the sky varies so much in its brightness from hour to hour, and from season to season.

B-4.2 Different visual tasks need differing amounts of lights for the same visual efficiency. The correct amount of light for any task is determined by the following:

a) *Characteristics of the tasks* — Size of significant detail, contrast of detail with background and how close it is to the eyes;

b) *Sight of the worker* — For example, old people need more light;

c) Speed and accuracy necessary in the performance of work. If no errors are permissible, much more light is needed; and

d) *Ease and comfort of working* — Long and sustained tasks should be done easily whereas workers can make a special effort for tasks of very short duration.

These factors have been made the subject of careful analysis as a result of which tables of necessary levels of illumination have been draw up.

B-4.3 Levels of lighting determined analytically shall be translated into levels of daylight and then into size of window opening or vice versa for checking the size of window assumed for required levels of daylight.

B-4.4 One of the many important factors involved in the translation is the lightness of the room surface. The illumination levels in a given room with a finite window will be higher when the walls are light coloured than when these are dark coloured. It is necessary, therefore, at an early stage to consider the colouring of the rooms of the building and not to leave this until later. Lighting is not merely a matter of window openings and quite half the eventual level of lighting may be dependent on the decoration in the room. Whatever may be the colour the occupant wants to use, it is most desirable to maintain proper values of reflectance factors for ceiling, wall and floors so that the level of daylight illumination is maintained.

ANNEX C

(*Clauses* 4.2.6 *and* 5.4.4.3)

USE OF DESIGN CHARTS FOR NATURAL VENTILATION

C-1 APPLICATION OF THE DESIGN CHARTS

C-1.1 The application of the design charts for natural ventilation (NV) is demonstrated here. The openings for the master-bedroom of the apartment two BHK case in Fig. 26 are sized to deliver the recommended airflow rates for two scenarios of input parameters.

C-1.2 The input parameters used for the demonstration of the design charts are shown in Table 23. The demonstration is shown for DC-01 in Fig. 26, for DC-02 in Fig. 27, for DC-03 in Fig. 28 and for DC-04 in Fig. 29. The free area for the openings A_f calculated with the DCs are shown in Table 25.

C-1.2.1 *DC*-01 — *Buoyancy-Driven Flow*; *Single-Sided Ventilation with One Opening*

$$A_\mathrm{f} = \frac{q_\mathrm{rec}}{C_\mathrm{d}} \sqrt{\frac{(T_\mathrm{inside} + 273)}{g\, h_\mathrm{a} \Delta T_\mathrm{inside\text{-}outside}}}$$

where

A_f = free area of the openings for NV, m^2;

C_d = discharge coefficient [-];

q_{rec} = ventilation rate achieved, m^3/s;

T_{inside} = temperature inside, °C;

g = acceleration due to gravity, m/s^2;

h_a = vertical distance between the centres of the openings, m; and

$\Delta T_{inside\text{-}outside}$ = [temperature inside (°C) - temperature outside (°C)].

DC-01 is derived from the equation given in **C-1.2.1**. For single openings, the value for C_d adopted is 0.25. The demonstration of the application of this DC for two scenarios (a set of values) and for the input parameters as per Table 23 is shown in Fig. 27.

C-1.2.2 *DC*-02 — *Buoyancy-Driven Flow*; *Cross-Ventilation with Multiple Openings Shown in Fig. 28*

The DC-02 is also derived from the equation given in **C-1.2.3.1**. Conversely, for multiple openings, the value for C_d adopted is 0.61. The demonstration of the application of this DC for two scenarios (a set of values) and for the input parameters shown in Table 23 is shown in Fig. 28.

C-1.2.3 *DC*-03 — *Wind-Driven Flow*; *Single-Sided Ventilation with One Opening Shown in Fig. 29*

DC-03 is derived from the following equation:

$$A_f = q_{rec}/CV_z$$

where

A_f = free area of the openings for NV, m^2;

q_{rec} = ventilation rate achieved, m^3/s;

C = opening shape coefficient, [-]; and

V_z = wind speed at height 'Z', m/s.

C-1.2.3.1 The wind speed is calculated based on the height of the opening and the wind profile adjusted according to the terrain roughness. The equation below defines the wind speed (V_z) at height 'Z' based on the mean wind velocity at 10 m height (V_{ref}) and the characteristics of the roughness of the terrain, employed as an exponent of this power law. For this demonstration 'city terrain' is adopted in the calculations of V_z (input parameters and calculated values are shown in Table 23 and Table 24).

$$V_z = V_{ref}\, k\, z^{\alpha} (\text{m/s})$$

where

V_z = wind speed at height 'Z', m/s;

V_{ref} = mean wind velocity, m/s;

k = terrain-roughness coefficient;

z = height above ground level, m; and

α = terrain roughness exponent.

iv)	City	0.33	0.21

C-1.2.3.2 The demonstration of the application of this DC for both scenarios of Indian cities and for the input parameters shown in Table 23 is shown in Fig. 29.

C-1.2.4 *DC-*04 — *Wind-Driven Flow*; *Cross-Ventilation with Multiple Openings is Derived from the Equation:*

$$A_f = q_{rec}\left(C_d V_z \sqrt{\frac{\Delta C_p}{2}}\right)^{-1}$$

C-1.2.4.1 For orthogonal wind and for the floor plan presented in Fig. 26 for the two bedroom, kitchen and hall, apartment block a pressure coefficient difference (ΔC_p) between inlets and outlets of 0.36 is adopted for this application demonstration (*see* Table 23).

C-1.2.5 The free areas of the openings calculated utilizing the four design charts provided in this design guide for the recommended airflow rates presented in Table 23 and for two scenarios of Indian cities, are given in Table 25.

LIST OF STANDARDS

The following list records those standards which are acceptable as 'good practice' and 'accepted standards' in the fulfilment of the requirements of this NBCS. The latest version of a standard shall be adopted at the time of enforcement of this NBCS. The standards listed may be used as a guide in conformance with the requirements of the referred clauses in this NBCS.

National Building Code Sectional Committee, CED 46

FOREWORD

This NBCS (Part D/Section 2) covers the general requirements for electrical and allied installations in buildings. For more details, it is essential to refer to the relevant Indian Standards on the subject.

This Section was first published in 1970 as part of the National Building Code of India and was subsequently revised in 1983, 2005 and 2016. In the first revision in 1983, general guidance for electrical wiring installation in industrial location where voltage supply normally exceeds 650 V was included. This Section was also updated based on the existing version of the Indian Standards. The importance of pre-planning and exchange of information among all concerned agencies from the earlier stages of building work was emphasized.

In the second revision of 2005, the title of this Section was modified from the erstwhile 'Electrical Installations' to 'Electrical and Allied Installations' to reflect the provisions included on certain allied installations. The significant changes incorporated in this revision included, thorough change in the risk assessment procedure for lightning including some other changes in the provision of lightning protection of building; alignment of some of the provisions of wiring with the practices prevalent at that time; modification of definitions in line with terminologies used at national and international levels and addition of some new definitions; incorporation of provisions on installation of distribution transformer inside the multistoreyed buildings; introduction of concept of energy conservation in lighting and introduction of concept of various types of earthing in building installations.

In the third revision in 2016, various updates were made including: location and other requirements relating to layout, environmental and safety aspects for different substation apparatus/equipment and generating sets were reviewed and updated; location of compact substations was included; requirements for electrical supply system for life and safety services were included; provisions relating to reception and distribution of supply and wiring installations were updated; installation best practices of energy meters were updated; discrimination, cascading and limitation concepts for the coordination of protective devices in electrical circuits were introduced; socket outlets with suitable circuit breakers, conforming to Indian Standards were recommended for industrial and commercial applications, either indoors or outdoors; provisions relating to earthing/grounding were substantially revised and updated; provisions relating to lightning protection of buildings were revamped based on the national and international developments then; provisions relating to renewable energy sources for building, such as solar PV system, aviation obstacle lights, electrical supply for electric vehicle charging and car park management, etc, were included; provisions relating to electrical installations for construction sites and demolition sites were included; provisions relating to protection of human beings from electrical hazards and protection against fire in the building due to leakage current were included; typical formats for checklists for handing over and commissioning of substation equipment and earthing pit were included; and the terminologies updated.

In this revision, the publication has been renamed as National Building Construction Standards (NBCS).

All electrical installations in India come under the purview of *The Indian Electricity Act*, 2003 and the rules and regulations framed thereunder. In the context of the buildings, both buildings (the structure itself) and the building services (not just the electrical services, but all other services that use electricity or have an interface with the electrical system) are required to follow these. The erstwhile *Indian Electricity Rules*, 1956 were modified by various Central Electricity Authority Regulations. While revising the provisions of this Section of the NBCS, care has been taken to align the same with the provisions of the relevant regulations, particularly, *Central Electricity Authority* (*Measures Relating to Safety and Electric Supply*) *Regulations*, 2023. In this revision, in addition to above, the following major modifications have been incorporated:

a) Various terms and their definitions have been reviewed based on current developments at national and international level. In addition, few more definitions have been added for more clarity and better understanding;

b) Voltage categorization for building has been made considering revision in voltage norms by CEA, Indian Standards and various State Electricity Boards;

c) Provisions relating to location and other requirements relating to layout, environmental and safety aspects for different substation apparatus/equipment and generating sets have been reviewed and updated;

d) Requirements for electrical supply system for life and safety services have been reviewed;

e) Provisions relating to reception and distribution of supply and wiring installations have been updated with due cognizance to Indian Standards formulated for various wiring systems;

f) Provisions relating to installation of energy meters have been updated;

g) Discrimination, cascading and limitation concepts for the coordination of protective devices in electrical circuits have been updated;

h) Socket-outlets with suitable circuit breakers, conforming to IS 1293 : 2019 'Plugs and socket-outlets for household and similar purposes of rated voltage up to and including 250 V and rated current up to and including 16 A — Specification (*fourth revision*)' have been recommended for industrial and commercial applications, either indoors or outdoors.

j) Provisions relating to earthing/grounding have been substantially revised and updated;

k) Provisions relating to lightning protection of buildings have been reviewed and updated based on the current national and international developments;

m) Provisions relating to renewable energy sources for building, such as rooftop solar photovoltaic (PV) system has been updated and building integrated photovoltaic (BIPV) system and solar water heating system have been included;

n) Provisions relating to electrical installations for construction sites and demolition sites have been reviewed and updated;

p) Provisions related to electric vehicles (EV) charging have been updated as per present norms;

q) Provisions relating to protection of human beings from electrical hazards and protection against fire in the building due to leakage current have been reviewed and updated;

r) Provisions on building management systems (BMS) have been updated in **10.4**; and

s) Provisions on power fence (electrical fence) system has been included in **10.11**.

This Section has to be read together with Part D 'Building Services, Section 1 Lighting and Natural Ventilation' of this NBCS for making provision for the desired levels of illumination as well as ventilation for different locations in different occupancies; Part D 'Building Services, Section 6 Information and Communication Enabled Installations'; Part F 'Fire and Life Safety' of this NBCS for list of emergency fire and life safety services and other sections of Part D 'Building Services' and Part E 'Plumbing Services' for electricity related requirements and integration thereof. Utmost importance should be given in the installation of electrical wiring to prevent short circuiting and the hazards associated therewith.

Notwithstanding the provisions given in this Section and the National Electrical Code 2023, the provisions of the *Central Electrical Authority* regulations framed under the *Indian Electricity Act*, 2003 as amended up to date have to be necessarily complied with.

The information contained in this section is largely based on the following Indian Standards/Special Publications:

IS 732 : 2019	Code of practice for electrical wiring installations (*fourth revision*)
IS 3043 : 2018	Code of practice for earthing (*second revision*)
IS 4648 : 1968	Guide for electrical layout in residential buildings
IS 19127 : 2025	Graphical symbols for diagrams in the field of electrotechnology
IS/IEC 62305-1 : 2010	Protection against lightning: Part 1 General principles
IS/IEC 62305-2 : 2010	Protection against lightning: Part 2 Risk management
IS/IEC 62305-3 : 2010	Protection against lightning: Part 3 Physical damage to structures and life hazard

IS/IEC 62305-4 : 2010	Protection against lightning: Part 4 Electrical and electronic systems within structures
IS 17017-1 : 2018	Electric vehicle conductive charging system: Part 1 General requirement
IS 17017-2 : 2020	Electric vehicle conductive charging system: Part 2 Plugs, socket-outlets, vehicle connectors, and vehicle inlets (*all sections*)
IS 18925 : 2025 (Parts 1 to 8)	Lightning protection system components
SP 30 : 2023	National Electrical Code of India, 2023 (*second revision*)

It may be noted that some of the above standards are currently under revision. The revised version when available should be referred.

Considerable assistance has also been drawn from following International Standards while formulating this Section:

IEC 62305 : 2024	Protection against lightning:
(Part 1) : 2024	General principles
(Part 2) : 2024	Risk management
(Part 3) : 2024	Physical damage to structures and life hazard
(Part 4) : 2024	Electrical and electronic systems within structures
IEC 60335-2-76 : 2018	Household and similar electrical appliances — Safety — Part 2-76: Particular requirements for electric fence energizers
IEC 60364-4-41 : 2005	Low-voltage electrical installations — Part 4-41: Protection for safety — Protection against electric shock
IEC 60364-4-43 : 2023	Low-voltage electrical installations — Part 4-43: Protection for safety — Protection against overcurrent
IEC 60364-4-44 : 2007	Low-voltage electrical installations — Part 4-44: Protection for safety — Protection against voltage disturbances and electromagnetic disturbances
IEC 60364-5-51 : 2005	Electrical installations of buildings — Part 5-51: Selection and erection of electrical equipment – Common rules
IEC 60364-5-54 : 2011	Low-voltage electrical installations — Part 5-54: Selection and erection of electrical equipment — Earthing arrangements and protective conductors
IEC 60364-7 series	Low-voltage electrical installations — Part 7: Requirements for special installations or locations
IEC 61439-1 : 2020	Low-voltage switchgear and controlgear assemblies — Part 1: General rules
IEC 61439-2 : 2020	Low-voltage switchgear and controlgear assemblies — Part 2: Power switchgear and controlgear assemblies
IEC 61439-6 : 2012	Low-voltage switchgear and controlgear assemblies — Part 6: Busbar trunking systems (busways)

All standards, whether given herein above or cross-referred to in the main text of this Section, are subject to revision. The parties to agreement based on this Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

As the regulation of land development and buildings is a State subject and is dealt by the States and local bodies such as urban local bodies within their jurisdiction through building regulatory documents like building regulations, building byelaws, and fire regulations, this document is voluntary in nature and is non-binding. The implementation depends on adoption by concerned parties or stipulations in a contract or by appropriate adoption by the concerned authorities.

For the purpose of deciding whether a particular requirement of this Section is complied with, the final value, observed or calculated, expressing the result of a test or analysis, shall be rounded off in accordance with IS 2 : 2022 ‘Rules for rounding off numerical values (*second revision*)’. The number of significant places retained in the rounded off value should be the same as that of the specified value in this Section of the NBCS.

This Page has been Intentionally left blank

Important Explanatory Note for Users of this NBCS

In any Part/Section of this NBCS, where reference is made to **'good practice'** in relation to design, constructional procedures or other related information, and where reference is made to **'accepted standard'** in relation to material specification, testing, or other related information, the Indian Standards listed at the end of the Part/Section shall be used as a guide to the interpretation.

At the time of publication, the editions indicated in the standards were valid. All standards are subject to revision and parties to agreements based on any Part/Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

In the list of standards given at the end of a Part/Section, the number appearing within parentheses in the first column indicates the number of the reference of the standard in the Part/Section. For example:

a) Good practice [D-2(1)] refers to the Indian Standard/Special Publication given at serial number (1) of the List of Standards given at the end of this Part D/Section 2, that is, SP 30 : 2023, 'National Electrical Code of India, 2023 (*second revision*)'

NATIONAL BUILDING COSTRUCTION STANDARDS

PART D BUILDING SERVICES

SECTION 2 ELECTRICAL AND ALLIED INSTALLATIONS

1 SCOPE

This NBCS (Part D/Section 2) covers the essential requirements for electrical installations in buildings to ensure efficient use of electricity including safety from fire and shock, reliability and sustainability. This Section also includes general requirements relating to renewable energy sources, EV charging, lightning protection of buildings and brief provisions on allied installations.

2 TERMINOLOGY AND CONVENTIONAL SYMBOLS

2.1 For the purpose of this Section, the following definitions shall apply. For definition of other terms, reference may be made to good practice [D-2(1)] and accepted standard [D-2(2)].

2.1.1 *Accessory* — A device, other than current using equipment, associated with such equipment or with the wiring of an installation.

2.1.2 *Apparatus* — Electrical apparatus including all machines, appliances and fittings in which conductors are used or of which they form a part.

2.1.3 *Appliance* — An item of current using equipment other than a luminaire or an independent motor.

2.1.4 *Back-up Protection* — Protection which is intended to operate when a system fault is not cleared or abnormal condition not detected in the required time, because of failure or inability of other protection to operate or failure of appropriate circuit-breaker to trip.

2.1.5 *Barrier* — A part providing a defined degree of protection against contact with live parts, from any usual direction of access.

2.1.6 *Basic Protection* — Protection against electric shock under fault-free condition.

NOTE — For low voltage installations, systems and equipment, basic protection generally corresponds to protection against direct contact that is ‘contact of persons or live parts’.

2.1.7 *Battery Energy Storage System* (*BESS*) — Electrical energy storage system with an accumulation subsystem based on batteries fitted with secondary cells.

2.1.8 *Bonding Conductor* — A protective conductor providing equipotential bonding.

2.1.9 *Bonding Ring Conductor* (*BRC*) — A bus earthing conductor in the form of a closed ring.

NOTE — Normally the bonding ring conductor, as part of the bonding network, has multiple connections to the common bonding network (CBN) that improves its performance.

2.1.10 *Branch Switch* — A miniature circuit breaker that protects a specific branch circuit within a larger power distribution circuit, such as a house or building. It acts as a safety device, automatically interrupting the flow of electricity in the event of an overload or short circuit, preventing damage to wiring and appliances.

2.1.11 *Bunched* — Cables are said to be ‘bunched’ when two or more are contained within a single conduit, duct, ducting, or trunking, or, if not enclosed, are not separated from each other.

2.1.12 *Buried Direct* — A cable laid in the ground in intimate contact with the soil.

2.1.13 *Busbar Trunking System* — A type-tested assembly, in the form of an enclosed conductor system of comprising solid conductors separated by insulating materials. The assembly may consist of units such as:

a) Busbar trunking units, with or without tap-off facilities;

b) Tap-off units where applicable; and

c) Phase-transposition, expansion, building-movement, flexible, end-feeder and adaptor units.

2.1.14 *Bypass Equipotential Bonding Conductor* — Bonding conductor connected in parallel with the screens of cables.

2.1.15 *Cable* — A length of single-insulated conductor (solid or stranded), or two or more such conductors, each provided with its own insulation, which are laid up together. The insulated conductor or conductors may or may not be provided with an overall mechanical protective covering.

2.1.16 *Cable*, *Fire Survival* — A cable which continues to function and maintain the circuit integrity under circumstances of fire (against a specified temperature and period of the test) {*see* accepted standards [D-2(3)]}.

2.1.17 *Cable, Flame Retardant* (*FR*) — A cable which is flame retardant as per the accepted standard [D-2(4)].

2.1.18 *Cable*, *Flame Retardant Low Smoke and Halogen* (FR-LSH) — A cable which is flame retardant and emits low smoke and halogen as per the accepted standard [D-2(5)].

2.1.19 *Cable*, *Flexible* — A cable containing one or more cores, each formed of a group of wires, the diameters of the cores and of the wires being sufficiently small to afford flexibility.

2.1.20 *Cable*, *Metal-Sheathed* — An insulated cable with a metal sheath.

2.1.21 *Cable*, *PVC Sheathed-Insulated* — A cable in which the insulation of the conductor is a polyvinylchloride (PVC) compound; with PVC sheath also providing mechanical protection to the conductor core or cores in the cable.

2.1.22 *Cable*, *Weatherproof* — A cable so constructed that when installed in uncovered locations, it will withstand all kinds of weather variations (*see* **2.1.195** for definition of weatherproof).

2.1.23 *Cable*, *XLPE* — A cable in which the insulation of the conductor is cross-linked polythene and the mechanical protection is provided for the core or cores by a sheath of a polyvinyl chloride compound.

2.1.24 *Cable Armoured* — A cable provided with a wrapping of metal (usually in the form of tape or wire) serving as a mechanical protection.

2.1.25 *Cable Bracket* — A cable support consisting of single devices fixed to elements of building or plant construction.

2.1.26 *Cable Channel* — An enclosure situated above or in the ground, open or ventilated or closed, and having dimensions which do not permit the access of persons but allow access to the conductor and/or cables throughout their length during and after installation.

NOTE — A cable channel may or may not form part of the building construction.

2.1.27 *Cable Cleat* — A component of a support system which consists of elements spread at intervals along the length of the cable or conduits and which mechanically retains the cable or conduit.

2.1.28 *Cable Coupler* — A means enabling the connection, at will, of two flexible cables. It consists of a connector and a plug.

2.1.29 *Cable Ducting* — A manufactured enclosure of metal or insulating material, other than conduit or cable trunking, intended for the protection of cables which are drawn-in after erection of the ducting, but which is not specifically intended to form part of a building structure.

2.1.30 *Cable Ladder* — A cable support occupying less than 10 percent of the plan area and consisting of a series of supporting elements rigidly fixed to each other or to a main supporting member or members.

2.1.31 *Cable Raceways* — An enclosed channel of metal or non-metallic materials designed expressly for holding wires, cables or busbars, with openable/maintainable construction having provision of ventilation. These include electrical non-metallic tubing, electrical metallic tubing, underfloor raceways, cellular concrete floor raceways, cellular metal floor raceways, surface raceways and wireways.

2.1.32 *Cable Support and Fixing Materials* (*Fire Survival*) — Supports and fixing materials for supporting fire survival cable (*see* **2.1.16**), which continues in service after exposure to fire for a specified duration.

2.1.33 *Cable Tray* — A cable support consisting of a continuous base with raised edges and no covering. The classification and perforation of cable tray shall be as per accepted standard [D-2(6)].

2.1.34 *Cable Trunking* — A factory made closed support and protection system into which conductors and/or cables are laid after removal of the cover.

2.1.35 *Cable Tunnel* — An enclosure (corridor) containing supporting structures for conductors and/or cables and joints and whose dimensions allow free access to persons throughout the entire length.

2.1.36 *Cartridge Fuse Link* — A device comprising a fuse element or several fuse elements connected in parallel enclosed in a cartridge usually filled with an arc-extinguishing medium and connected to terminations. The fuse link is the part of a fuse which requires replacing after the fuse has operated.

2.1.37 *Ceiling Rose* — A fitting (usually used to attach to the ceiling) designed for the connection between the electrical installation wiring and a flexible cord (which is in turn connected to a lamp holder).

2.1.38 *Circuit* — An assembly of electrical equipment supplied from the same origin and protected against overcurrent by the same protective device(s). Circuits are categorized as follows:

a) *Category* 1 *circuit* — A circuit (other than a fire alarm annunciation or emergency lighting circuit and other circuits required to work during fire in a building) operating at low voltage and supplied directly from a mains supply system;

b) *Category* 2 *circuit* — With the exception of Category 3 circuits, any circuit for extra low-voltage (ELV)/telecommunication [for example, radio, telephone, sound distribution, building management system (BMS), public address system (PAS), intruder alarm, bell and call and data transmission circuits] which is supplied from a safety source; and

c) *Category* 3 *circuit* — A fire alarm circuit or an emergency lighting circuit and other circuits required to work during fire in a building.

2.1.39 *Circuit Breaker* — A mechanical switching device, capable of making, carrying and breaking currents under normal circuit conditions and also of making, carrying for a specified time, and breaking currents under specified abnormal circuit conditions such as those of short circuit.

NOTE — A circuit breaker is usually intended to operate infrequently, although some types are suitable for frequent operation.

2.1.39.1 *Miniature circuit breaker* (*MCB*) — A compact mechanical switching device capable of making, carrying and breaking currents under normal circuit conditions and also making and carrying currents for specified times and automatically breaking currents under specified abnormal circuit conditions, such as those of overload and short circuits.

2.1.39.2 *Circuit breaker*, *linked* — A circuit breaker, the contacts of which are so arranged as to make or break all poles simultaneously or in a definite sequence.

2.1.39.3 *Moulded case circuit breaker* (*MCCB*) — A circuit breaker having a supporting housing of moulded insulating material forming an integral part of the circuit breaker.

2.1.39.4 *Air circuit breaker* (*ACB*) — A circuit breaker in which the contacts open and close in air at atmospheric pressure.

2.1.40 *Circuit*, *Final Sub* — An outgoing circuit connected to one-way distribution board and intended to supply electrical energy at one or more points to current, using appliances without the intervention of a further distribution board other than a one-way board. It includes all branches and extensions derived from that particular way in the board.

2.1.41 *Compact Substation or Prefabricated Substation* — Prefabricated and type-tested assembly which can to be operated from inside (walk-in type) or outside (non-walk-in type) comprising components such as power transformer, high-voltage switchgear and controlgear, low-voltage switchgear and controlgear, corresponding interconnections (cable, busbar or other) and auxiliary equipment and circuits located next to each other, maintaining segregation and integrity of each compartment in which they are located along with external interconnecting cables, earthing, protections, etc. The components shall be enclosed by either a common enclosure or by an assembly of enclosures.

NOTE — *See* accepted standard [D-2(7)] for requirements of prefabricated substation.

2.1.42 *Conductor, Aerial* — Any conductor which is supported by insulators above the ground and is directly exposed to the weather.

NOTE — Following four classes of aerial conductors are recognized:

a) Bare aerial conductors;

b) Covered aerial conductors;

c) Insulated aerial conductors; and

d) Weatherproof neutral-screened cable.

2.1.43 *Conductor*, *Bare* — A conductor not covered with insulating material.

2.1.44 *Conductor, Earthed* — A conductor with no provision for its insulation from earth.

2.1.45 *Conductor*, *Insulated* — A conductor adequately covered with insulating material of such quality and thickness as to prevent danger.

2.1.46 *Conductor of a Cable or Core* — The conducting portion consisting of a single wire or group of wires, assembled together and in contact with each other or connected in parallel.

2.1.47 *Conduit* — A part of a closed wiring system, a circular or non-circular cross section for conductors and/or cables in electrical installations, allowing them to be drawn in and/or replaced. Conduits should be sufficiently closed-jointed so that the conductors can only be drawn in and not inserted laterally.

2.1.48 *Connector* — The part of a cable coupler or of an appliance coupler which is provided with female contact and is intended to be attached to the flexible cable connected to the supply.

2.1.49 *Connector Box or Joint Box* — A box forming a part of wiring installation, provided to contain joints in the conductors of cables of the installations.

2.1.50 *Connector for Portable Appliances* — A combination of a plug and socket arranged for attachment to a portable electrical appliance or to a flexible cord.

2.1.51 *Consumer's Terminals* — The ends of the electrical conductors situated upon any consumer's premises and belonging to him, at which the supply of energy is delivered from the service line.

2.1.52 *Continuous Operating Voltage* (U_c) — Maximum rms voltage which may be continuously applied to a surge protection device's mode of protection. This is equal to rated voltage.

2.1.53 *Cord, Flexible* — A flexible cable having a large number of strands of conductors of small cross-sectional area. Two flexible cords twisted together are known as twin ‘flexible cord’.

NOTE — Large number of fine strands of wires for each conductor makes the conductor capable of withstanding frequent bends thereby improving their flexibility.

2.1.54 *Core of a Cable* — A single conductor of a cable with its insulation but not including any mechanical protective covering.

2.1.55 *Current Carrying Capacity of a Conductor* — The maximum current which can be carried by a conductor under specified conditions without its steady state temperature exceeding a specified value.

2.1.56 *Current Using Equipment* — Equipment which converts electrical energy in to another form of energy, such as light, heat, or motive power.

2.1.57 *Cut-out* — Any appliance for automatically interrupting the transmission of energy through any conductor when the current rises above a pre-determined amount.

2.1.58 *Damp Situation* — A situation in which moisture is either permanently present or intermittently present to such an extent as likely to impair the effectiveness of an installation conforming to the requirements for ordinary situations.

2.1.59 *Danger* — Danger to health or danger to life or limb from shock, burn or injury from mechanical movement to persons (and livestock where present), or from fire attendant upon the use of electrical energy.

2.1.60 *Datacentre* — A structure, or group of structures, dedicated to the centralized accommodation, interconnection and operation of information technology and network telecommunications equipment providing data storage and processing with the necessary levels of resilience and security required to provide the desired service availability.

2.1.61 *Dead* — A portion of an electrical circuit (normally expected to carry a voltage) at or near earth potential or apparently disconnected from any live system. A circuit apparently disconnected from all sources is expected to be at earth potential; but capacitive storage of charge in cables, capacitors, etc, can keep the electric circuit at a significant voltage (and often dangerous voltages from aspects of shock). Such circuits with storage components will be dead only on connection to earth.

2.1.62 *Design Current* (*of a Circuit*) — The magnitude of the current intended to be carried by the circuit in normal service.

2.1.63 *Direct Contact* — Contact of persons or live stock with live parts which may result in electric shock.

2.1.64 *Discrimination* (*Selectivity-Over-Current Discrimination*) — Coordination of the operating characteristics of two or more over-current protective devices should be such that, on the incidence of over-currents within stated limits, the device intended to operate would be the device closest to the point of fault or abnormality, and if proper discrimination is achieved within these limits, only that device closest should operate, while the other circuit breakers upstream do not operate, thereby ensuring that there is minimum area of power supply which is interrupted.

NOTES

1 Protective devices should have discrimination so that only the affected part (minimum section) of the circuit is isolated, even though a number of protective devices may be in the path of the overcurrent.

2 The electrical network requires the discrimination for all the fault circuits, including overload, short-circuit, etc. The downstream device should take care of the fault up to the level of ultimate short-circuit breaking capacity (*I*cu) of the downstream breaker which should be equal to the bus which is connected.

3 Distinction is made between series discrimination involving different over-current protective devices passing substantially the same over-current and network discrimination involving identical protective devices passing different proportions of the over-current.

4 Different types of protective devices may have to be used to ensure effective discrimination in circuits where proper and effective discrimination is necessary. Apart from the built-in sensors and actuators in circuit breakers, external relays operating on different parameters, and comparison of parameters between two or more points will have to be used for complex installations.

5 *See also* relevant parts of the accepted standard [D-2(8)].

2.1.65 *Disconnector* — A mechanical switching device which, in the open position, complies with the requirements specified for the isolation function.

NOTES

1 A disconnector is otherwise known as isolator.

2 A disconnector is capable of opening and closing a circuit when either a negligible current is broken or made, or when no significant change in the voltage across the terminals of each pole of the disconnector occurs. It is also capable of carrying currents under normal circuit conditions and carrying for a specified time, current under abnormal conditions, such as those of short-circuit.

2.1.66 *Distance Area or Resistance Area* (*for an Earth Electrode Only*) — The surface area of ground (around an earth electrode) on which a significant voltage gradient may exist.

2.1.67 *Diversity Factor* — A measure of the probability that a particular piece of equipment will turn on coincidentally to another piece of equipment. For aggregate systems it is defined as the ratio of the sum of the individual non-coincident maximum loads of various subdivisions of the system to the maximum demand of the complete system.

2.1.68 *Duct* — A closed passage way formed underground or in a structure and intended to receive one or more cables which may be drawn in.

2.1.69 *Ducting — See* **2.1.29**.

2.1.70 *Earth* — The conductive mass of the earth, whose electric potential at any point is conventionally taken as zero.

2.1.71 *Earth Continuity Conductor* — The conductor, including any clamp, connecting to the earthing lead or to each other, those parts of an installation which are required to be earthed. It may be in whole or in part, the metal conduit or the metal sheath or armour of the cables, or the special continuity conductor of a cable or flexible cord incorporating such a conductor.

2.1.72 *Earthed Concentric Wiring* — A wiring system in which one or more insulated conductors are completely surrounded throughout their length by a conductor, for example a sheath, which acts as a PEN conductor.

2.1.73 *Earth Electrode* — A conductor or group of conductors in intimate contact with the ground to provide a low resistance path for flow of current to earth.

2.1.74 *Earth Electrode Network* — Part of an earthing arrangement comprising of only the earth electrodes and their interconnections.

2.1.75 *Earth Electrode Resistance* — The resistance of an earth electrode to earth.

2.1.76 *Earth Fault* — An unintended and undesirable connection of phase/neutral conductor to earth. When the impedance is negligible, the connection is called a dead earth fault.

2.1.77 *Earth Fault Current* — A current resulting from a fault of negligible impedance between a line conductor and an exposed conductive part or a protective conductor.

2.1.78 *Earth Fault Loop Impedance* (Z_s) — The total impedance of the path that a fault current would take during an earth fault, starting at the point of the fault and returning to the supply's neutral point.

2.1.79 *Earthing* — Connection of the exposed conductive parts of an installation to the main earthing terminal of that installation.

2.1.80 *Earthing Conductor* — A protective conductor connecting the main earth terminal (or equipotential bonding conductor of an installation when there is no earth bus) to an earth electrode or to other means of earthing.

2.1.81 *Earthing Lead* — The final conductor by which the connection to the earth electrode is made.

2.1.82 *Earth Leakage Current* — A current which flows to earth, or to extraneous conductive parts, in a circuit which is electrically sound.

NOTE — This current may have a capacitive component including that resulting from the deliberate use of capacitors.

2.1.83 *Earthing Resistance*, *Total* — The resistance between the main earthing terminal and the earth.

2.1.84 *Electrical Equipment* (*abb: Equipment*) — Any item for such purposes as generation, conversion, transmission, distribution or utilization of electrical energy, such as machines, transformers, apparatus, measuring instruments, protective devices, wiring materials, accessories, and appliances.

2.1.85 *Electrically Independent Earth Electrodes* — Earth electrodes located at such a distance from one another that the maximum current likely to flow through one of them does not significantly affect the potential of the other(s).

2.1.86 *Electrical Supply System for Life and Safety Services* — A supply system intended to maintain the operation of essential parts of an electrical installation and equipment:

a) for health and safety of persons and livestock; and
b) to avoid damage to the environment and to other equipment.

NOTES

1 The supply system includes the source and the circuit(s) up to the terminals of the electrical equipment.

2 *See also* Part F 'Fire and Life Safety' of this NBCS regarding emergency fire and life safety services.

2.1.87 *Electric Shock* — A dangerous patho-physiological effect resulting from the passing of an electric current through a human body or an animal.

2.1.88 *Electric Vehicle* (*EV*) — A vehicle that is propelled by one or more electric motors, using electrical energy stored in rechargeable batteries offering various benefits, including reduced emissions, lower running costs and potentially quieter operation compared to traditional gasoline-powered vehicles.

2.1.89 *EV Connector* — Different types of EV charging connectors, also called plugs, that works with different vehicles, charging speeds and locations.

2.1.90 *Electric Vehicle Supply Equipment* (*EVSE*) — Equipment or a combination of equipment, providing dedicated functions to supply electric energy from a fixed electrical installation or supply network to an EV for the purpose of charging.

2.1.91 *Emergency Switching* — Rapid cutting off of electrical energy to remove any hazard to persons, livestock, or property which may occur unexpectedly.

2.1.92 *Enclosure* — A part providing protection of equipment against certain external influences and, in any direction, protection against direct contact.

2.1.93 *Enclosed Distribution Board* — An enclosure containing busbars with one or more control and protected devices for the purpose of protecting, controlling or connecting more than one outgoing circuits fed from one or more incoming circuits.

2.1.94 *Equipotential Bonding* — Electrical connection putting various exposed conductive parts and extraneous conductive parts at a substantially equal potential.

NOTE — In a building installation equipotential bonding conductors shall interconnect the following conductive parts:

a) Protective conductor;
b) Earth continuity conductor; and
c) Risers of air conditioning system and heating systems (if any).

2.1.95 *Exothermic Welding* — A welding process that uses a chemical reaction to generate intense heat, typically reaching temperatures of around 1 400 °C. This heat is used to melt metal and create a permanent, high-quality weld without the need for an external heat or power source. The process is particularly useful for joining conductors, such as in earthing and lightning protection systems, and can be used to weld dissimilar metals.

2.1.96 *Exposed Conductive Part* — A conductive part of electrical equipment, which can be touched and which is not normally live, but which may become live under fault conditions.

2.1.97 *Exposed Metal* — All metal parts of an installation which are easily accessible other than:

a) parts separated from live parts by double insulation;

b) metal name-plates, screw heads, covers, or plates, which are supported on, or attached, or connected to substantial non-conducting material only in such a manner that they do not become alive in the event of failure of insulation of live parts and whose means of fixing do not come in contact with any internal metal; and

c) parts which are separated from live parts by other metal parts which are themselves earthed or have double insulation.

2.1.98 *External Influence* — Any influence external to an electrical installation which affects the design and safe operation of that installation.

2.1.99 *Extraneous Conductive Part* — A conductive part not forming part of the electrical installation and liable to introduce a potential, generally the earth potential.

2.1.100 *Fault* — A circuit condition in which current flows through an abnormal or unintended path. This may result from an insulation failure or a bridging of insulation. Conventionally the impedance between live conductors or between live conductors and exposed or extraneous conductive parts at the fault position is considered negligible.

2.1.101 *Fault Current* — A current resulting from a fault.

2.1.102 *Fault Protection* — Protection against electric shock under single fault conditions.

NOTE — For low voltage installation, system's and equipment's fault protection generally corresponds to protection against indirect contact, mainly with regards to failure of basic insulation. Indirect contact is 'contact of persons or livestock with exposed-conductive parts which have become live under fault conditions'.

2.1.103 *Final Circuit* — A circuit connected directly to current using equipment, or to socket-outlets or other outlet points for the connection of such equipment.

2.1.104 *Fire Survival Distribution Board* — A distribution board which continues in service after exposure to fire to the required system rating.

2.1.105 *Fish Wire* — A draw wire to pull electrical wires or other cables through concealed spaces like conduits in ceilings/walls/floors.

2.1.106 *Fitting, Lighting* — A device for supporting or containing a lamp or lamps [for example, fluorescent or incandescent or halogen or compact fluorescent lamp (CFL) or light-emitting diode (LED)] together with any holder, shade, or reflector, for example, a bracket, a pendant with ceiling rose, an electrolier, or a portable unit.

2.1.107 *Fixed Equipment* — Equipment fastened to a support or otherwise secured.

2.1.108 *Flameproof Enclosure* — An enclosure which will withstand without injury any explosion of inflammable gas that may occur within it under practical conditions of operation within the rating of the apparatus (and recognized overloads, if any, associated therewith) and will prevent the transmission of flame which may ignite any inflammable gas that may be present in the surrounding atmosphere.

NOTES

1 Hazardous areas are classified into different zones, depending upon the extent to which an explosive atmosphere may exist at that place. In such areas, flame proof switchgear, fittings, accessories have to be used/installed in flameproof enclosure.

2 An electrical apparatus is not considered as flameproof unless it complies with the appropriate statutory regulations.

3 Other types of fittings are also in vogue in wiring installations, for example, 'increased safety'.

2.1.109 *Functional Earthing* — Connection to earth necessary for proper functioning of electrical equipment.

2.1.110 *Hand-Held Equipment* — Portable equipment intended to be held in the hand during normal use, in which the motor, if any, forms an integral part of the equipment.

NOTE — A hand held equipment is an item of equipment, the functioning of which requires constant manual support or guidance.

2.1.111 *Harmonics* (*Current and Voltage*) — All alternating current which is not absolutely sinusoidal is made up of a fundamental and a certain number of current and voltage harmonics [multiples of 50 Hz (basic frequency)] which are the cause of its deformation (distortion) when compared to the theoretical sine-wave.

2.1.112 *Hazardous Live-Part* — A live part which can give, under certain condition of external influence, an electric shock.

2.1.113 *Impulse Current* — A parameter used for the classification test for SPDs (*see* **2.1.177**); it is defined by three elements, a current peak value, a charge Q and a specific energy W/R.

2.1.114 *Impulse Withstand Voltage* — The highest peak value of impulse voltage of prescribed form and polarity which does not cause breakdown of insulation under specified condition.

2.1.115 *Indirect Contact* — Contact of persons or livestock with exposed conductive parts made live by a fault and which may result in electric shock.

2.1.116 *Industrial Plugs and Sockets* — Plugs and socket-outlets, cable couplers and appliance couplers, primarily intended for industrial use, either indoors or outdoors.

NOTE — For the purpose of this NBCS, industrial plugs and sockets conforming to accepted standards [D-2(9)] shall be used for industrial purpose.

2.1.117 *Inflammable Material* — A material capable of being easily ignited.

2.1.118 *Installation* (*Electrical*) — An assembly of associated electrical equipment to fulfil a specific purpose or purposes and having coordinated characteristics.

2.1.119 *Insulated* — Insulated shall mean separated from adjacent conducting material or protected from personal contact by a non-conducting substance or an air space, in either case offering permanently sufficient resistance to the passage of current or to disruptive discharges through or over the surface of the substance or space, to obviate danger or shock or injurious leakage of current.

2.1.120 *Insulation* — Suitable non-conducting material, enclosing, surrounding or supporting a conductor.

2.1.120.1 *Insulation*, *basic* — Insulation applied to live parts to provide basic protection against electric shock and which does not necessarily include insulation used exclusively for functional purposes.

2.1.120.2 *Insulation*, *double* — Insulation comprising both basic and supplementary insulation.

NOTE — Double insulation for small hand held equipment allows them to be used without a safety earth connection, without shock risk of such hand held equipment.

2.1.120.3 *Insulation*, *reinforced* — Single insulation applied to live parts, which provides a degree of protection against electric shock equivalent to double insulation under the conditions specified in the relevant standard.

NOTE — The term ‘single insulation’ does not imply that the insulation is a homogeneous piece. It may comprise several layers which cannot be tested singly as supplementary or basic insulation.

2.1.120.4 *Insulation*, *supplementary* — Independent insulation applied in addition to basic insulation in order to provide protection against electric shock in the event of a failure of basic insulation.

2.1.121 *Inverter* — Electric energy converter that changes direct electric current to single-phase or polyphase alternating currents.

2.1.122 *Isolation* — Cutting off an electrical installation, a circuit, or an item of equipment from every source of electrical energy.

2.1.123 *Isolator* — A mechanical switching device which, in the open position, complies with the requirements specified for the isolating function. An isolator is otherwise known as a disconnector.

2.1.124 *Junction Box* — A box forming a part of wiring installation, intended to conceal electrical connections and joints of conductors/cables in order to protect the connection from external influences such as direct contact, dust, water, moisture, UV radiation, etc depending upon the protection requirement of the space or utility.

2.1.125 *Leakage Current* — Electric current in an unwanted conductive path under normal operating conditions.

2.1.126 *LEMP Protection Measures* (*SPM*) — Measures taken to protect internal systems against the effects of LEMP.

2.1.127 *Lightning Electromagnetic Impulse* (*LEMP*) — All electromagnetic effects of lightning current *via* resistive, inductive and capacitive coupling that create surges and radiated electromagnetic fields.

2.1.128 *Lightning Protection* — Complete system for protection of structures against lightning, including their internal systems and contents, as well as persons, in general consisting of an LPS and SPM.

2.1.129 *Lightning Protection Level* (*LPL*) — A number related to a set of lightning current parameters values relevant to the probability that the associated maximum and minimum design values will not be exceeded in naturally occurring lightning.

NOTE — Lightning protection level is used to design protection measures according to the relevant set of lightning current parameters.

2.1.130 *Lightning Protection System* (*LPS*) — Complete system used to reduce physical damage due to lightning flashes to a structure.

2.1.130.1 *Lightning protection system*, *External* — Part of the LPS consisting of an air-termination system, a down-conductor system and an earth-termination system.

2.1.130.2 *Lightning protection system, Internal* — Part of the LPS consisting of lightning equipotential bonding and/or electrical insulation of external LPS.

2.1.131 *Lightning Protection Zone* — Zone where the lightning electromagnetic environment is defined.

2.1.132 *Line Conductor* — A conductor of an a.c. system for the transmission of electrical energy other than a neutral conductor or a PEN conductor. This also means the equivalent conductor of a d.c. system unless otherwise specified in this NBCS.

2.1.133 *Live Part* — A conductor or conductive part intended to be energised in normal use including a neutral conductor but, by convention, not a PEN conductor.

2.1.134 *Live or Alive* — Electrically charged so as to have a potential different from that of earth.

2.1.135 *Locations*, *Industrial* — Locations where tools and machinery requiring electrical wiring are installed for manufacture or repair.

2.1.136 *Locations*, *Non-Industrial* — Locations other than industrial locations, and shall include residences, offices, shops, showrooms, stores and similar premises requiring electrical wiring for lighting, or similar purposes.

2.1.137 *Low-Voltage Switchgear and Controlgear Assembly* — A combination of one or more low voltage switching devices together with associated control, measuring, signalling, protective, regulating equipment, etc, completely assembled under the responsibility of the manufacturer with all the internal electrical and mechanical interconnections and structural parts. The components of the assembly may be electromechanical or electronic.

2.1.138 *Luminaire* — Equipment which distributes, filters or transforms the light from one or more lamps and which includes any parts necessary for supporting, fixing and protecting the lamps, but not the lamps themselves, and, where necessary, circuit auxiliaries together with the means for connecting them to the supply.

NOTE — For the purposes of this NBCS a batten lamp holder, or a lamp holder suspended by flexible cord, is a luminaire.

2.1.139 *Main Earthing Terminal* — The terminal or bar which is the equipotential bonding conductor of protective conductors and conductors for functional earthing, if any, to the means of earthing.

2.1.140 *Meshed Bonding Network* (*MESH-BN*) — Bonding network in which all associated equipment frames, racks and cabinets and usually the d.c. power return conductor are bonded together as well as at multiple points to the CBN and may have the form of a mesh.

2.1.141 *Mobile Equipment* — Electrical equipment which is moved while in operation or which can be easily moved from one place to another while connected to the supply.

2.1.142 *Monitoring* — Observation of the operation of a system or part of a system to verify correct functioning or detect incorrect functioning by measuring system variables and comparing the measured value with the specified value.

2.1.143 *Multiple Earthed Neutral System* — A system of earthing in which the parts of an installation specified to be earthed are connected to the general mass of earth and, in addition, are connected within the installation to the neutral conductor of the supply system.

2.1.144 *Neutral Conductor* — Includes the conductor of a three-phase four-wire system; the conductor of a single-phase or d.c. installation, which is earthed by the supply undertaking (or otherwise at the source of the supply), and the middle wire or common return conductor of a three-wire d.c. or single-phase a.c. system.

2.1.145 *Origin of an Electrical Installation* — The point at which electrical energy is delivered to an installation.

NOTE — An electrical installation may have more than one origin.

2.1.146 *Overcurrent* — A current exceeding the rated value. For conductors the rated value is the current carrying capacity.

2.1.147 *Overload Current* (*of a Circuit*) — An overcurrent occurring in a circuit in the absence of an electrical fault.

2.1.148 *PEN Conductor* — A conductor combining the functions of both protective conductor and neutral conductor.

2.1.149 *Phase Conductor* — *See* **2.1.132**.

2.1.150 *Plug* — A device, provided with contact pins, which is intended to be attached to a flexible cable and which can be engaged with a socket-outlet or with a connector.

2.1.151 *Point* (*in Wiring*) — A termination of the fixed wiring intended for the connection of current using equipment.

2.1.152 *Portable Equipment* — Equipment which is moved while in operation or which can easily be moved from one place to another while connected to the supply.

2.1.153 *Protection*, *Ingress* — The degree of protection against intrusions (body parts such as hands and fingers), dust, accidental contact and water.

NOTE — The classification of degrees of ingress protection provided by enclosures for electrical equipment shall be as per the accepted standard [D-2(10)].

2.1.154 *Protection*, *Mechanical Impact* — The degrees of protection provided by enclosures for electrical equipment against external mechanical impacts.

NOTE — The classification of degrees of protection against mechanical impact provided by enclosures for electrical equipment shall be as per accepted standard [D-2(10)]

2.1.155 *Prospective Fault Current* (I_{pf}) — The value of overcurrent at a given point in a circuit resulting from a fault of negligible impedance between live conductor having a difference of potential under normal operating conditions, or between a live conductor and an exposed-conductive part.

2.1.156 *Protective Conductor* — A conductor used for some measures of protection against electric shock and intended for connecting together any of the following parts:

a) Exposed conductive parts;

b) Extraneous conductive parts;

c) Main earthing terminal; and

d) Earthed point of the source, or an artificial neutral.

2.1.157 *Protective Conductor Current* — Electric current appearing in a protective conductor, such as leakage current or electric current resulting from an insulation fault.

2.1.158 *Protective Earthing* — Earthing of a point or points in a system or in equivalent, for the purpose of safety.

2.1.159 *Protective Separation* — Separation of one electric circuit from another by means of:

a) double insulation;

b) basic insulation and electrically protective screening (shielding); or

c) reinforced insulation.

2.1.160 *Rated Current* — Value of current used for specification purposes, established for a specified set of operating conditions of a component, device, equipment or system.

2.1.161 *Rated Impulse Withstand Voltage Level* (U_w) — The level of impulse withstand voltage assigned by the manufacturer to the equipment, or to part of it, characterizing the specified withstand capability of its insulation against overvoltage.

2.1.162 *Residual Current* — The algebraic sum of the instantaneous values of current flowing through all live conductors of a circuit at a point of the electrical installation.

2.1.163 *Residual Current Device* (*RCD*) — Mechanical switching device or association of devices designed to make, carry and break currents under normal service conditions and to cause the opening of the contacts when the residual current attains a given value under specified conditions.

2.1.164 *Residual Current Operated Circuit Breaker with Integral Overcurrent Protection* (*RCBO*) — A residual current operated circuit breaker designed to perform the functions of protection against overload and/or short-circuit.

2.1.165 *Residual Current Operated Circuit-Breaker without Integral Overcurrent Protection* (*RCCB*) — A residual current operated circuit breaker not designed to perform the functions of protection against overload and/or short-circuits.

2.1.166 *Residual Operating Current* — Residual current which causes the residual current device to operate under specified conditions.

2.1.167 *Service* — The conductors and equipment required for delivering energy from the electric supply system to the wiring system of the premises served.

2.1.168 *Shock Current* — A current passing through the body of a person or an animal and having characteristics likely to cause dangerous patho-physiological effects.

2.1.169 *Short-Circuit Current* — An overcurrent resulting from a fault of negligible impedance between live conductors having a difference in potential under normal operating conditions.

2.1.170 *Space Factor* — The ratio (expressed as a percentage) of the sum of the overall cross-sectional areas of cables (including insulation and sheath) to the internal cross-sectional area of the conduit or other cable enclosure in which they are installed. The effective overall cross-sectional area of a non-circular cable is taken as that of a circle of diameter equal to the major axis of the cable.

2.1.171 *Standby Supply System* — A system intended to maintain supply to the installation or part thereof, in case of interruption of the normal supply, for reasons other than safety of persons.

NOTE — Standby supplies are necessary, for example, to avoid interruption of continuous industrial processes or data processing.

2.1.172 *Stationary Equipment* — Either fixed equipment or equipment not provided with a carrying handle and having such a mass that it cannot easily be moved.

2.1.173 *Step Voltage* — The potential difference between two points on the earth's surface, separated by distance of one pace, that will be assumed to be one metre in the direction of maximum potential gradient.

2.1.174 *Socket-Outlet* — A device, provided with female contacts, which is intended to be installed with the fixed wiring and intended to receive a plug.

NOTE — A luminaire track system is not regarded as a socket-outlet system.

2.1.175 *Substation* — A facility containing power/distribution transformers interconnecting two or more networks of different voltages.

2.1.176 *Surge* — A transient created by LEMP (*see* **2.1.127**) that appears as an overvoltage and/or an overcurrent.

2.1.177 *Surge Protective Devices* (*SPD*) — A device intended to limit transient overvoltages and divert surge currents. It contains at least one non-linear component. Types of SPDs are as follows:

a) *Type* 1 *SPDs* (*Surge Arresters*) — For protection of high-energy surges, caused by direct lightning strikes or switching surges from utility grid, installed at the service entrance near the main distribution board;

b) *Type* 2 *SPDs* (*Transient Voltage Surge Suppressors or TVSS*) — For protection against secondary surges caused by utility grid switching or internal electrical faults. Installed in electrical distribution panel/sub-distribution board; and

c) *Type* 3 *SPDs* (*Plug-in Surge Protectors*) — For providing localized protection for sensitive electronic equipment like computers and TVs installed near the point of use.

2.1.178 *Sustainability* — Under electrical this refers to the generation of electricity using renewable sources such as solar, wind, hydro, geothermal and bioenergy that are naturally replenished and have minimal negative impact on the environment and to meet present energy needs without compromising the ability of future generations to meet their own, promoting long-term energy security and environmental protection.

2.1.179 *Switch* — A mechanical switching device capable of making, carrying and breaking current under normal circuit conditions, which may include specified operating overload conditions; and also of carrying for a specified time currents under specified abnormal circuit conditions, such as those of short circuit.

NOTE — A switch may also be capable of making, but not breaking, short-circuit currents.

2.1.180 *Switchboard* — An assembly of switchgear with or without instruments, but the term does not apply to a group of local switches in a final circuit.

NOTE — The term 'switchboard' includes a distribution board.

2.1.181 *Switch Disconnector* — A switch which, in the open position, satisfies the isolating requirements specified for a disconnector.

NOTE — A switch disconnector is otherwise known as an isolating switch.

2.1.182 *Switch Disconnector Fuse* — A composite unit, comprising a switch with the fuse contained in or mounted on the moving member of the switch.

2.1.183 *Switch*, *Linked* — A switch, the contacts of which are so arranged as to make or break all poles simultaneously or in a definite sequence.

2.1.184 *Switchgear* — An assembly of main and auxiliary switching apparatus for operation, regulation, protection or other control of electrical installations.

2.1.185 *Systems*, *Earthing* — An electrical system consisting of a single source or multiple sources running in parallel of electrical energy and an installation. Types of system are identified as follows, depending upon the relationship of the source and of exposed-conductive parts of the installation, to earth:

a) *TN system* — A system having one or more points of the source of energy directly earthed, the exposed conductive-parts of the installation being connected to that point by protective conductors;

b) *TN-C system* — A system in which neutral and protective conductor functions are combined in a single conductor throughout the system;

c) *TN-S system* — A system having separate protective conductor throughout the system;

d) *TN-C-S system* — A system in which neutral and protective conductor functions are combined in a single conductor in part of the system;

e) *TT system* — A system having one point of the source of energy directly earthed, the exposed-conductive-parts of the installation being connected to the earth electrodes electrically independent of the earth electrodes of the source. This is also known as direct earthing system; and

f) *IT system* — A system in which all live parts are isolated from earth or one point connected to earth through an impedance. The exposed-conductive-parts of the electrical installation are earthed independently or collectively or to the earthing of the system.

NOTE — The types of systems depending upon the relationship to the source and of the exposed conductive parts of the insulations to earth are defined in good practice [D-2(11)].

2.1.186 *Thermal Runaway* — An unstable condition arising during constant voltage charging in which the rate of heat generation exceeds the heat dissipation capability, causing a continuous temperature increase and a further rise in charging current, which can lead to battery destruction.

2.1.187 *Touch Voltage* — The potential difference between the ground potential rise (GPR) of a grounded metallic structure and the surface potential at the point where a person could be standing while at the same time having a hand in contact with the grounded metallic structure. Touch voltage measurements can be 'open circuit' (without the equivalent body resistance included in the measurement circuit) or 'closed circuit' (with the equivalent body resistance included in the measurement circuit) voltage by which an installation or part of an installation is designated.

2.1.188 *Usable Wall Space* — All portions of a wall, except that occupied by a door in its normal open position, or occupied by a fire place opening, but excluding wall spaces which are less than 1 m in extent measured along the wall at the floor line.

2.1.189 *Utility Building* — A standalone separate single or two storied service building structure outside the main building structure meant for only accommodating services' spaces, such as electric substation, diesel generator plant room, a.c. plant room, plumbing plant room, sewerage treatment plant, medical gases, electrical and mechanical maintenance rooms. Such buildings do not have any permanent occupancy other than by personnel on duty.

2.1.190 *Voltage Nominal* (*of an Installation*) — Voltage by which an installation or part of an installation is designated.

2.1.191 *Voltage*, *Extra Low* (*ELV*) — The voltage which does not normally exceed 50 V.

2.1.192 *Voltage*, *Low* (*LV*) — The voltage which normally exceeds 50 V but does not normally exceed 1 000 V in a.c. (alternating current) and 1 500 V in d.c. (direct current).

2.1.193 *Voltage*, *High* (*HV*) — The voltage which normally exceeds 1 000 V a.c. but less than or equal to 33 kV.

2.1.194 *Voltage*, *Extra High* (*EHV*) — The voltage, which normally exceeds 33 kV.

NOTE – The Central Electricity Authority and the Bureau of Indian Standards introduced norms for different voltages during 2017-2018, which have been adopted in good practice [D-2(1)]. These norms may differ from those adopted by various State Governments in India. In buildings across India over the past 75 years, 11 kV and 33 kV have been termed as high tension/high voltage. Electrical control switchgears available for 11 kV/33 kV are known as high voltage switchgears. Accordingly, the voltage norms specified in **2.1.191** to **2.1.194** are adopted for buildings in relation to this NBCS.

2.1.195 *Weatherproof* — Accessories, lighting fittings, current-using appliances and cables are said to be of the weatherproof type with ingress protection according to the application, if they are so constructed that when installed in open situation they will withstand the effects of rain, snow, dust and temperature variations.

2.2 Conventional Symbols

The architectural symbols that are to be used in all drawings, wiring plans, etc, for electrical installations in buildings shall be as given in Annex A.

For other graphical symbols used in electrotechnology, reference may be made to good practice [D-2(1)].

3 GENERAL REQUIREMENTS

3.1 Statutory Requirements

All electrical installations that are in use/being executed shall conform to *The Indian Electricity Act*, 2003 and *Central Electricity Authority* (*Measures Relating to Safety and Electric Supply*) *Regulations*, 2023 as amended up to date; and rules if any made there under. This NBCS covers brief information about the statutory requirements.

NOTE — After India's independence, India formulated *The IE Rules*, 1956 based on *The IE Act*, 1910. Thereafter in 2003, Government of India adopted *The Electricity Act*, 2003 and nominated CEA to adopt necessary regulations for electrical supply, safety, generation and distribution. Based on these directions, CEA issued *Central Electricity Authority* (*Measures Relating to Safety and Electric Supply*) *Regulations* in 2010 which is superseded with *CEA Regulations*, 2023. Consequent to this, *The IE Act*, 1910 and *IE Rules*, 1956 have been repealed. The norms for voltages under regulations were established by CEA during 2017-18 and based on the same good practice [D-2(12)] was issued in 2018 which has been adopted by good practice [D-2(1)]. Under this, good practice [D-2(1)] has categorized up to 33 kV as medium voltage. However, all State Electricity Boards have fixed voltage norms which are different from CEA/NEC norms. It has been the practice for over 75 years to refer to 11 kV and 33 kV as high tension or high voltage in buildings. Hence, it has been decided to give separate voltage norms for buildings in this NBCS.

3.1.1 *The Electricity Act*, 2003

Section 53 of *The Electricity Act*, 2003, states requirements relating to 'Provisions relating to safety and electrical supply'. Some of the important points included in this NBCS are protecting the public from the dangers arising out of electricity, reducing the risk of personal injury, and damage to property. In accordance, Central Electricity

Authority under Section 70 of the Act, has been empowered to specify suitable measures. Such measures are updated and notified from time to time in the form of regulations. It may be noted that any failure to comply with any order, or any attempt or abetment that contravenes the rules and regulations framed under the act, may attract appropriate action as per the provisions therein.

NOTE — It may be noted that any failure to comply with any order, or any attempt or abetment that contravenes the rules and regulations framed under the Act, may attract appropriate action as per Section 146 of the Act. Section 149 decides responsibility and Section 150 stipulates that any act of abetment in relation to an offence may invite appropriate consequences. It means that the persons who is not directly involved in construction of electrical installation but indirectly relate to integrated part of electrical installation, such as architectural or civil construction, such as keeping provision of spaces, reserving routes, maintaining clearances, civil construction with required fire rating, etc come under the ambit of these sections. Accepted standard [D-2(13)] provides list of such stakeholders involved in electrical installation.

3.1.2 *Central Electricity Authority*

The Central Electricity Authority, formed under Section 70, is empowered to make regulations as directed under Section 53 and Section 177 of the *Indian Electricity Act*, 2003. In accordance, the following regulations have been notified and are in force. However, reference shall always be made to the latest versions/amendments.

3.1.2.1 *Central Electricity Authority* (*Measures relating to Safety and Electric Supply*) *Regulations*, 2023

These regulations state various requirements to be observed in the following activities:

a) Design;

b) Construction;

c) Verification and testing;

d) Maintenance;

e) Use;

f) Electric supply; and

g) Various activities integrated with the work of electrical installation.

NOTE — Regulation No. 14 (2) requires electrical installations to follow relevant standards, including this NBCS, the National Electrical Code of India, or the International Standards, where Indian Standards are unavailable. So, though the BIS Standards and Codes of practice are guidelines, their observance is no longer optional but mandatory when read with Section 146 of the Act.

3.1.2.2 *Central Electricity Authority* (*Technical Standards for the Construction of Electrical Plants and Electrical Lines*) *Regulations*, 2022

From the perspective of this NBCS, these regulations apply to transmission and distribution licensees. That is, whenever any electrical line, whether overhead or underground, passes through the plot area of the building/building-complex, observance of these provisions, which are in the scope of the respective owner of the line, may require verification.

NOTE — Important sections of the above regulations are given in Annex B.

3.2 Project Management of Electrical Works

3.2.1 From the perspective of project management, electrical work activities shall broadly be divided into the following stages:

a) Planning;

b) Designing;

c) Construction;

d) Verification and testing; and

e) Maintenance.

NOTE — For existing buildings, (a) to (c) may not apply unless there is a major change or complete renovation.

3.2.2 *Coordination*

At all work stages and the activities within these stages, different persons/agencies concerning planning, civil construction and building services are involved. Mutual coordination between the stakeholders involved, directly or indirectly, is very important to avoid conflicts.

3.3 Stakeholders and their Responsibility

The role of stakeholders is very important in streamlining electrical work. Accepted standard [D-2(13)] identifies stakeholders as below:

a) Owner/developer;

b) Architect;

c) Civil contractor;

d) Other service providers;

e) Electrical consultant;

f) Electrical contractor;

g) Electrical inspector; and

h) Electricity supplier.

The standard states the responsibility of each stakeholder as per the related statutory compliances, quoting the clauses from related regulations, standards and codes. While assuming responsibility, each stakeholder shall have the required qualifications and experience in the respective field as set out in rules, regulations, bylaws, or any government notification. Where such eligibility criteria are not mandated, it will be the responsibility of the employer to appoint a person with qualifications and experience comparable to similar/correlating tasks. In addition, the provisions given in accepted standard [D-2(13)] may also be complied with.

NOTE — Most of the time, the electrical contractor who executes the work follows the design received from the consultant. But, for an electrical consultant who plays a key role of electrical design, there are no set rules or regulations to determine eligibility or accreditation procedures. Under the circumstances, until such rules come into force, reference to **3.5** from accepted standard [D-2(13)] may be taken, or the qualification and experience of such a person may be considered on par with the Chartered Electrical Safety Engineer as stated in regulation 6 of the *CEA* (*Measures Relating to Safety and Electric Supply*) *Regulations*, 2023 (*see* Annex B).

It should be noted that appointing technical experts like consultants/contractors from respective fields and assigning them responsibility are inherent parts of project management and need to be observed at the planning stage.

3.4 Appointment of Technical Professionals Concerning Electrical Installation

In addition to the requirements stated in accepted standard [D-2(13)], an electrical engineer shall be appointed on site as a registered building professional to streamline, monitor and certify, jointly with the consultant and the electrical contractor, all works relating to electrical services.

3.5 Roles and Responsibilities of the Persons Appointed for Electrical Work

There shall be a written agreement between the developer and the appointee deciding the scope of work and the responsibilities to be undertaken. Such an agreement shall include a declaration concerning the work the appointee will undertake (*see* Annex G).

3.5.1 *Electrical Engineer on Site*

To monitor the coordination of work between all stakeholders, from planning to completion, the electrical engineer on site has an important role. In the team of technical persons often referred to as 'Registered building professional' or 'Licensed technical professional/person', with different nomenclature in various building rules/regulations/byelaws, the inclusion of an electrical engineer shall be treated as an important requirement for controlling and monitoring electrical work activities. His duties and functions shall be:

a) observe all regulatory requirements;

b) maintain coordination between all stakeholders;

c) check electrical requirements from the perspective of location and spaces in the architectural plans;

d) check the electrical design prepared by the design consultant;

e) check specifications related to material and method of construction;

f) participate in preparing the activities chart, considering the smooth and coordinated work progress;

g) monitor and maintain surveillance from planning to completion and handing over, with special attention to the work that will be concealed;

h) check and jointly sign certificates/declarations and checklists as recommended in accepted standard [D-2(13)];

j) check required NOCs/Permissions from respective authorities; and

k) maintain a record of all documents.

3.5.2 *Electrical Consultant*

To perform the desired role as an electrical consultant, he shall have the necessary qualifications and experience. Reference may be taken from the note under **3.3**. Such a person shall have an updated knowledge of all regulatory requirements, standards and codes of practice related to the design, construction, verification, testing, and maintenance of electrical work. He shall be responsible for preparing designs with drawings and specifications that adhere to quality standards. He shall consult the architect regarding necessary points to consider at the planning and construction stage. Table 1 from accepted standard [D-2(13)] provides a list of activities and responsibilities. Some important points in this regard are given below:

a) Identify the existing overhead and underground electrical lines on the proposed development plot and the mandatory requirements, compliances, and NOCs related to clearances;

b) Spaces, locations and routes of the distribution network required for electrical installation;

c) Specific requirements related to RCC structure (static/dynamic load of electrical equipment, requirement of recess within RCC structure to avoid core cutting, required height between finished floor level and soffit of the beam);

d) Specific requirement related to wall thickness to accommodate concealed electric boxes, raised floor (false flooring) to accommodate cable work below;

e) Specific requirements where an aluminium formwork system is used to cast concrete for building elements like walls, floors, columns, beams and slabs. Similar provisions have to be used in case of prefabricated concrete works;

f) Specific requirements related to ventilation and avoiding the accumulation of heat;

g) Assessment of electrical load including future expansion (while assessing load, other service providers shall be consulted for their requirements);

h) Space requirement for the electrical sub-station as per the assessment of the required load. *See* Annex D for suggested space provision as per the substation's capacity;

j) Consult with the electric supply company for load sanction and requirements, if any, such as space/room (*see* Note), etc;

NOTE — The supply company may state the requirement for space within the consumer's premises for substation/equipment. There may also be a case where there is no spare capacity or possibility to augment the existing electrical distribution. The consultant shall be well aware of the conditions of the Supply Code approved by the respective State Electricity Regulatory Commission and, in accordance, give the architect the requirements related to space. All related correspondence shall be documented.

k) Prepare drawings showing the electrical equipment locations and the electric supply distribution network on site plans. Supplier and consumer distribution networks shall be segregated;

m) Prepare drawings of electrical equipment rooms of substation, switch rooms and consult with the architect and civil engineer about the requirements related to technical specifications of civil construction like fire rating, ventilation facilities, doors/openings, ducts, floor level, clear ceiling height below beam soffit, access facility, dust-free areas, etc. Some of such requirements may be:

   1) *Transformer sub-station* — Oil draining arrangement, oil soak pit, curb to prevent the spread of spillage/leaked/drained oil, the required clearances around apparatus considering the type of transformer dry/oil-cooled (O class)/liquid-cooled (K class), adjacent structure whether combustible/non-combustible, provision of baffle wall, etc;

   2) *Standby power supply* — Genset, PUC norms, stack height and the building in the vicinity, safe location; and

   3) *Standby power supply* — UPS system, location and specific requirements related to battery storage.

n) Drawings showing proposed internal routes and layouts of cables (mains, sub-mains, circuit mains, light, fan power outlet points, distribution boxes, boards with electrical accessories, outlet points and the required clearances between other services, accessibility, etc;

   NOTE — Where aluminium formwork technology is used to cast concrete for building elements like walls, floors, columns, beams, and slabs, drawings showing precise locations of points and boxes are most important. Similar provisions have to be provided in case of prefabricated concrete works.

p) Design electrical installation with due consideration for general characteristics that adhere to protection for safety;

q) Consider the related requirements stated under the Energy Conservation Building Code to qualify buildings under a certain class;

r) Prepare specifications for the selection and erection of electrical equipment with due consideration to the factors of external influences;

s) State requirements relating to fire prevention, specific to electrical installation as given under CEA Regulations, for example, placement of extinguishers, PPE, automatic fire suppression system, etc;

t) State design requirements related EV charging stations and the clearances around;

u) State if there are any specific requirements relating to the access;

   NOTE — In the event, the electric control panel room is being located in the basement there shall be at least two independent access to the ground floor to avoid any one access getting blocked leading to a serious situation in accessing, operating and controlling the electric supply of critical services in case of fire.

w) Provide technical support and guidance to site engineers/contractors during project execution to ensure material and installation quality, and assist in resolving issues arising during installation, verification, and commissioning;

y) State requirements related to verifying and testing of electrical installations; and

z) Maintain respective checklists updated as required under the accepted standard [D-2(13)].

3.5.3 *Electrical Contractor**

Electrical contractor shall have a licence issued by the appropriate government. It shall be valid at the time of agreement and renewed when necessary. He shall be aware of the obligations mandated as per the rules and regulations. The supervisor(s) appointed by him shall have competency and updated technical knowledge of all regulatory requirements and the codes of practice. The contractor shall be responsible for:

a) Resolving differences regarding the design, drawings, and specifications provided by the consultant, if any, and carrying out work as per the final design. In case of unresolved points, maintain the record;

   *NOTE — Where the electrical contractor is also performing the job of electrical consultant, he shall also be responsible for observing requirements stated under **3.5.2**.

b) Before commencing work, get the drawing approvals from the respective authority, where applicable;

c) Employ electrical supervisor and the workmen having permits of the appropriate class or designated as per regulation 3 of the *CEA* (*Measures Relating to Safety and Electric Supply*) *Regulations*, 2023 to carry out work on/for the electrical installation (*see* Annex B);

d) Weatherproof lockable storage space for materials at site to be arranged by the electrical contractor;

e) Observe workplace safety in respect of:

    1) temporary electrical installation on site; and

    2) provision of adequate tools and personal protective equipment (PPE) to workmen.

f) Check that requirements related to civil construction concerning electrical installation are satisfied;

g) Observe the activity chart based on a time schedule, which is mutually agreed upon between all concerned service providers and plan the work in coordination;

    NOTE — Where an aluminium formwork is used to cast concrete for building elements like walls, floors, columns, beams and slabs, the coordination with civil work needs to be observed precisely. Similar provisions have to be ensured in case of prefabricated concrete works.

h) Carry out electrical installation according to the plans and finalised design by the consultant or, where applicable, the design approved by the authority (electrical inspector);

j) The execution shall be according to the approved methods of construction stated under the National or International codes of practice, where the NBCS has not set any parameters;

k) All work should be executed under the strict supervision of a competent person with the necessary permit issued by the government;

m) A record of hidden work shall be maintained with certificates of required compliance, which shall be jointly signed with the engineer on site before concealing;

n) Maintain electrical installation safety throughout the construction period and the defect liability period;

p) Get the installation verified and tested, preferably through a third party, at the following stages:

    1) During construction; and

    2) After completion, before certifying for its beneficial use.

q) Help the electrical engineer on site in maintaining updated checklists as required under the accepted standards [D-2(13)]; and

r) Prepare handing-over documents for the respective owner, stating details of the electrical installation as given the checklist.

3.6 Materials

All materials, fittings, appliances, etc used in electrical and allied installations, shall conform to Part B ‘Building Materials’ of this NBCS and other concerned Indian Standards.

3.7 Coordination with Local Supply Authority

a) In all cases, that is, whether the proposed electrical work is a new installation or extension of an existing one, or a modification involving major changes, the electricity supply undertaking shall be consulted about the feasibility, etc, at an early date. The wattage per square metre and permissible diversity consideration shall be defined as per the type of building (residential, commercial, mercantile, industrial, retail, convention, exhibition, hotel, hospital, institution, flatted factory, group housing, etc). The wattage per square metre (W/m^2) shall be defined considering probable loads as per city grading such that future loading into the development is accounted; and

b) *Addition to an installation* — An addition, temporary or permanent, shall not be made to the authorized load of an existing installation, until it has been definitely ascertained that the current carrying capacity and the condition of existing accessories, conductors, switches, etc, affected, including those of the supply authority are adequate for the increased load. The size of the cable/conductor shall be suitably selected on the basis of the ratings of the protective devices. Ratings of protective devices and their types shall be based on the installed load, switching characteristics and power factor.

Load assessment and application of suitable diversity factor to estimate the full load current shall be made as a first step. This should be done for every circuit, submain and feeder. Power factor, harmonics (*see* **5.3.6.6**) and efficiency of loads shall also be considered. Diversity factor assumed shall be based on one's own experience or as per table under **4.2.2.2**. Allowance should be made for about 15 percent to 20 percent for extension in near future. The wiring system should be adopted taking into account the environmental requirements and hazards, if any in the building. The sizes of wiring cables are decided not merely to carry the load currents, but also to withstand thermal effects of likely overcurrents, short circuit and ensure acceptance level of voltage drop.

3.8 Power Factor Improvement in Consumers' Installation

3.8.1 Conditions of supply of electricity boards or licensees stipulate the lower-limit of power factor which is generally 0.95 lag or better.

3.8.2 Principal causes of low power factor are many. For guidance to the consumers of electric energy who take supply at low and medium voltages for improvement of power factor, reference shall be made to good practice [D-2(1)] and accepted standard [D-2(14)].

3.9 Execution of Work

Unless otherwise exempted under the appropriate regulation of the *CEA* (*Measures relating to Safety and Electric Supply*) *Regulations*, 2023 as amended from time to time, the work of electrical installations shall be carried out by a licensed electrical contractor and under the direct supervision of a person holding a certificate of competency and by persons holding a valid permit issued and recognized by the State government.

3.10 Safety procedures and practices shall be kept in view during execution of the work in accordance with accepted standard [D-2(15)].

3.11 Safety provisions given in Part F 'Fire and Life Safety' of this NBCS should be followed.

4 PLANNING OF ELECTRICAL INSTALLATIONS

4.1 General

The design and planning of an electrical wiring installation involve consideration of all prevailing conditions and is usually influenced by the type and requirements of the consumer. Various utility services including EV charging, ELV systems namely intercom, data cabling (*see* Part D 'Building Services, Section 6 Information and Communication Enabled Installations' of this NBCS), CCTV, fire detection, etc shall also be taken into account with anticipated future requirements. A competent electrical design engineer should be involved at the planning stage with a view to providing for an installation that will prove adequate for its intended purpose and ensure safety, reliability and energy efficiency in its use. The information/requirements given in **3** shall also be kept into consideration while designing and planning an electrical wiring installation. With the proliferation of the use of electrical and electronic devices in buildings as well as the increase in the generation/distribution capacities of power systems, the hazards of energy feed to a fault or defect in the electrical installation has increased. Reliability of power supply and continued supply even under abnormal conditions are becoming very important not only for the operation of services and activities in a building, but also for the life safety of occupants. . Electricity is linked to all services and addition of standby and emergency power supply systems adds to the complexity requiring proper coordinated design. Generally, it is not difficult to provide proper pathways and equipment installation spaces, if an integrated approach is taken from the beginning. The designs should also have to keep the availability of optimum access to installations to ensure proper maintenance. Considering various utility services and to avoid conflict amongst them, it is most important to estimate space requirement for electrical work including LV systems, at planning stage and allocate it in consultation with architect/civil engineer.

4.1.1 The design and planning of an electrical wiring installation shall take into consideration the following:

a) Type of supply, building utility, occupancy, envisaged load and the earthing arrangement available;

b) Provisioning and designing of circuits (circuit length, voltage drop and other aspects), cabling, equipment loads, selection of switchgears, protective devices, fittings and accessories, earthing system, electrical panel rooms, etc complete;

c) Climatic condition, such as cooling air temperature, moisture or such other conditions which are likely to affect the installation adversely including provisioning of air conditioning systems for present and/or future expansion;

d) Provisions for lightning protection system (LPS) based on risk assessment including using building structure for the purpose;

e) Possible presence of inflammable or explosive dust, vapour or gas;

f) Degree of electrical and mechanical protection necessary;

g) Importance of continuity of service including the possible need for standby supply;

h) Probability of need for modification or future extension;

j) Probable operation and maintenance cost taking into account the electricity supply tariffs available;

k) Relative cost of various alternative methods;

m) Need for radio and telecommunication interference suppression;

n) Ease of maintenance;

p) Safety aspects;

q) Energy conservation;

r) Importance of proper discrimination between protective devices for continuity of supply and limited isolation of only the affected portion;

s) Reliability of power supply and redundancy (of sources and distribution paths) to cater to the needs for emergency power and standby power for continued operation of systems as well as integration of alternate sources of energy such as diesel generation, solar energy, wind power, etc; and

t) Integration of different types of energy sources such as (single or multi) grid power, DG set power backup, battery storage energy system, on grid solar PV power, on grid other renewable energy sources such as wind power, micro wind wheel, etc.

NOTE — The design and planning of electrical installations shall also comply with relevant provisions of good practice [D-2(1)].

4.1.2 All electrical apparatus shall be suitable for the services these are intended for and shall confirm to relevant Indian Standards.

4.1.3 *Coordination*

Proper coordination and collaboration among the architect, civil engineer, electrical engineer and mechanical engineer shall be ensured from the planning stage of the installation. The electrical engineer shall be conversant with the needs of the electrical supply provider for making electrical supply arrangement. Electrical supplier's installation, as per regulations, needs to be segregated from consumer's installation. Wherever required, prior approval of drawings shall be taken from concerned electrical supplier/electrical inspector. Further, depending on load and regulation provisions, consumer will need to submit to the electrical supplier the details regarding the accommodation of substation including transformers, switch-rooms, standby power, solar photovoltaic panels, lighting and ventilation scheme for the approval. Additional information sought by the Authority regarding details of electrical safety apparatus, fire safety apparatus, cable ducts, rising mains and distribution cables, sub-distribution boards, openings in floors and walls, etc for all electrical installations shall be provided. Provisions as-given in accepted standard [D-2(13)] shall also be complied.

4.1.4 While planning wiring and installation of fittings and accessories, information should be exchanged between the owner of the building/architect/consultant/electrical contractor and the local supply authority in respect of tariffs applicable, types of apparatus that may be connected under each tariff, requirement of space for installing meters, switches, etc, and for total load requirements of lights, fans and power. Consideration should also be taken for the anticipated increase in the use of electricity for lighting, general purpose socket-outlet, kitchen equipment, air conditioning, utility sockets, heating, etc.

4.1.5 It is essential that adequate provision should be made for all the services which may be required immediately and during the intended useful life of the building. If not provided, the user may be tempted to carry out extension of the installation himself or to rely upon use of multi-plug adaptors and long flexible cords, both of which are not recommended.

4.2 Substation and Switchrooms

4.2.1 *Location and Other Requirements*

The location and other requirements of a substation and switchrooms shall be as given below:

a) Availability of power lines nearby may be kept in view while deciding the location of the substation.

b) The substation should preferably be located near the load centre in a separate utility building adjacent to the generator room, if any. Location of substation in the basement should be avoided, as far as possible. If it is unavoidable, the floor level of substation shall be at least 0.6 m above the lowest point of the basement.

c) In case of more than 2 basements in a building/buildings, the substation/switchroom shall be provided in either first or second basement with floor of the substation not more than 10 m below the adjoining (site) ground level.

d) In places where flooding can occur and water level may go above 1 000 mm, the base substation may be located on one level above the ground level of a utility building or of main building. In such cases, only one feeder should feed ground level and levels below with automatic tripping of the feeder to avoid electrocution in case of live electricity coming in contact with water. Designers shall use their discretion in special cases depending on the degree of reliability, redundancy and the category of load and make suitable provisions.

NOTE — In cases, where the substation is located one level above ground level of utility building or main building, this should be after due evaluation of the other risks posed by such a location combined with the concurrence for such a decision from State Electricity Authority comprising the electrical inspectorate and the distribution licensee and the fire service. There should be direct access from outside the building for substation without entering building to substation.

e) Depending upon the topology of the area (in mountains/stepped terrain), location of substation and DG set should be such that flooding of the equipment area is avoided, with substation and DG set located at least 300 mm above maximum flood level with natural drainage of the substation/DG sets areas.

f) Ideal location for an electrical substation for a group of buildings will be at the electrical load centre. Generally, the load centre will be somewhere between the geometrical centre and the air conditioning plant room, as air conditioning plant room will normally be the largest load, if the building(s) are centrally air conditioned.

g) In order to prevent storm water entering the transformer and switch rooms, the floor level of the substation/switchroom shall be at least 300 mm above the highest flood water level that may be anticipated in the locality. Also, facility shall be provided for automatic removal of water.

h) Substation shall not be located immediately above or below plumbing water tanks or sewage treatment plant (STP) water tanks at the same location.

j) All door openings from substation, electrical rooms, etc, should open outwards. Vertical shutters (like fire rated rolling shutters) may also be acceptable provided they are combined with a single leaf door opening outwards for exit in case of emergency. For large substation room/electrical room having multiple equipment, two or more doors shall be provided which shall be remotely located from each other.

k) If substation is located at a height 1 000 m above MSL, then adequate derating of equipment shall be considered.

m) HV panel room and transformers should have direct access and located as near as possible. In case HV panel and transformers are located at different floors or at a distance of more than 20 m, HV isolator shall be provided nearer to the transformer.

n) In case transformer and main HV/LV panel room are located at different floors, the designer should also take care of the safety requirements caused by lack of direct visibility of the status of the controlling switch. To cater to the safety requirements under different conditions of operation as well as maintenance, it may be necessary to provide additional isolator or an emergency push button in the vicinity to trip the supply. Decision has to be taken based on the possible risks.

p) No services or ventilation shafts shall open into substation or switch room unless specific to substation or switch room.

q) *Oil-filled installation* — Substations with oil-filled equipment require great consideration for the fire detection, protection and suppression. Oil-filled transformers require a suitable soak pit with gravity flow to contain the oil in the event of the possibility of oil spillage from the transformer on its failure. Installation of oil-filled equipment shall meet the following requirements:

    1) Substations with oil-filled equipment/apparatus (transformers and high voltage panels) shall be either located in open or in a utility building. They shall not be located in any floor other than the ground floor or the first basement of a utility building. They shall not be located below first basement slab of utility building. They shall have direct access from outside the building for operation and maintenance of the equipment.

    2) Substations/utility buildings (where the substation or oil-filled transformer is located) shall be separated from the adjoining buildings including the main building by at least 6 m clear distance to allow passage of fire tender between the substation/utility building and adjoining building/main building.

    3) There shall be no interconnecting basement with the main building underneath the oil-filled transformers.

    4) Provisions for oil drainage to a tank (from which oil can be decanted and reused) at a lower level and separated by adequate fire barrier shall be provided. If there is a floor directly below the ground floor level or first basement where the oil-filled transformers and oil-filled circuit breakers are placed, then they should be separated by a fire barrier of appropriate fire rating as per Part F 'Fire and Life Safety' of this NBCS and proper oil drainage system shall be provided to avoid possible leakage of oil into the lower floor.

    5) Substation equipment having more than 2 000 of oil whether located indoors in the utility building or outdoors shall have baffle walls of 4 h fire rating between apparatus (*see also* Part F 'Fire and Life Safety' of this NBCS for fire safety related requirements).

    6) Provisions shall be made for suitable oil tank, and where use of more than 9 000 litre of oil in any one oil tank, receptacle or chamber is involved, provision shall be made for the draining away or removal of any oil which may leak or escape from the tank, receptacle or chamber containing the same. Special precautions shall be taken to prevent the spread of any fire resulting from the ignition of the oil from any cause and adequate provision shall be made for extinguishing any fire which may occur.

    7) Oil filled transformers/stabilizers/auto transformers (with oil capacity more than 50 litre) or any equivalent electrical equipment shall not be used within the buildings other than utility buildings. Utility building should not be used for any other activity other than services. In case of less than 50 litre equipment placed in building, it should be kept in naturally ventilated areas and fire segregated from occupied areas and other areas prone to accidental fires.

    8) Adequate fire barriers or deflectors shall be provided to avoid flames from the substation reaching or affecting the adjacent areas including upper floors (*see also* Part F 'Fire and Life Safety' of this NBCS).

    9) Transformer, HV panel, LV isolator shall not be kept one above the other in a way that in case of oil leakage or fire in an equipment the other becomes unapproachable. Stacking of electrical equipment should not be done.

    10) For transformers having large oil content (more than 2 000 litre), *Rule* 46(2) of the *Central Electricity Authority* (*MRSES*) *Regulations*, 2023 shall apply (*see* Annex B).

r) *Dry-type installation* — In case electric substation has to be located within the main multi-storeyed building itself for unavoidable reasons, it shall be a dry-type installation with very little combustible material, such as, a dry type transformer with vacuum breakers as HT switchgear and ACB or MCCB as low voltage (LV) switchgear. Such substations shall be located on the ground level or on first basement and shall have direct access from the outside of the building for operation and maintenance of the equipment.

Exceptionally, in case of functional buildings, such as air traffic control towers, high rise non – residential buildings, data centres and mixed use buildings of height more than 150 m having high electrical load requirement, dry-type installations/substations may also be provided at upper level without emergency backup systems requiring diesel or any inflammable material storage. This measure will decrease the current flow and short-circuit rating at various points, thereby reducing vulnerability to fire. In such cases, a base substation shall be located at ground floor/first basement to cater to the main HV/LV panel which feeds life and safety services loads as defined in **4.2.1**(h). The base substation shall be located in such a way to provide direct access to the firemen in case of any emergency. The power supply control to any substation or transformer located at upper floors shall be from the base substation so that in case of fire, the electrical supply can be easily disconnected to avoid additional losses.

s) The power supply HV cables voltage shall not be more than 36 kV and a separate dedicated and fire compartmented shaft should be provided for carrying such high voltage cables to upper floors in a building. These shall not be mixed with any other shaft and suitable fire detection and suppression measures shall be provided throughout the length of the cable on each floor.

t) The provision for installation and removal of substation equipment should be provided from inside or outside the building without disturbing the associate major equipment in the substation. In case of inside building path a designated elevator should be installed which is capable of handling weight and size of transformer parts being transported to designated floor for installation, maintenance and removal from the floor.

u) In case of compact substation {*see* accepted standard [D-2(7)]}, design and location of the substation shall ensure safety of the people around the compact substation installed along walkways, playgrounds, etc. Compact substation with incomer voltage of 12 kV or less, when located in open areas shall have fencing or barrier (of any metal based protection, such as wire mesh or chain link, which is duly earthed) against unauthorized contact possibility around it at a minimum distance of 750 mm around it with access for maintenance from all four sides. For incomer voltage more than 12 kV and less than 24 kV the fencing distance from substation may be 1 000 mm minimum. In case of more than 24 kV incomer, the distance may be further increased accordingly. The fencing design should take care of the servicing and maintenance requirements of the substation equipment.

w) In case of two transformers (dry type or transformers with cumulative oil quantity less than 2 000 litre) located next to each other without intermittent wall, the distance between the two shall be minimum 1 500 mm for 11 kV, minimum 2 000 mm for 22 kV and 33 kV. Beyond 33 kV, two transformers shall be separated by baffle wall of 4 h fire rating.

y) Horizontal routing of HT cable through functional/occupied areas should be avoided in view of safety.

z) If dry type transformer is used, it may be located adjacent to high voltage switchgear in the form of unit type substation. In such a case, no separate room or fire barrier for the transformer is required either between transformers or between transformer and the switchgear, thereby decreasing the room space requirement. however, minimum distances as specified in **4.2.1**(w) shall be maintained between the apparatus depending upon voltage ratings. Layout of equipment should take care of the need that any one piece of equipment or sub-assembly can be taken out of service and out of the installed location, while keeping the remaining system in service. Working space for access for maintenance of equipment, while keeping an adjoining section of the substation live to maintain power supply to essential loads, may require additional space between such sections of equipment.

aa) For acoustical enclosures/treatment, reference may be made to Part D 'Building Services, Section 4 Acoustics, Sound Insulation and Noise Control' of this NBCS and CPCB norms requirements.

bb) The minimum recommended spacing between the walls and the transformer periphery from the point of proper ventilation shall be in accordance with good practice [D-2(16)] (*see also* Fig. 1A). The actual spacing may be more than those given in the figure, depending on the circumstances, such as access to the accessories. Other requirements relating to installation of transformers shall also be in accordance with good practice [D-2(16)].

cc) *High voltage switch room/space* — The design should take care of HV equipment space and clearance required around for maintenance and personnel safety as given in **5.3.6.8**. This room may preferably have direct access from outside. In case of substation having one transformer and one source of supply, the owner shall provide one high voltage switch. In case of single point supply with two or more transformers, the number of switch required will be one for incoming supply and one for each transformer. Additional space may be provided keeping in mind future extension, if any. In case of dual supply, two switches shall be provided with mechanical/electrical inter locking arrangement. In case the number of incoming and outgoing switches exceed five, bus coupler of suitable capacity should invariably be provided.

dd) *Low voltage switch room/space* — The floor area required in respect of low voltage switchgear room may be determined keeping in view the number and type of incoming, outgoing, bus coupler switches including likely expansion in future, space requirement as given in **5.3.6.8**. The additional requirements of LV switchroom when located separate from the substation shall be as per **4.4**.

ee) Other requirements relating to installation of switchgears and controlgears as given in good practice [D-2(17)] shall also be complied with.

ff) The minimum height of substation room/HV switch room/LV switch room shall be arrived at considering 1 200 mm clearance requirement from top of the equipment to below the soffit of the beam (*see also* Annex C). In case cable entry/exit is from above the equipment (transformer, HV switchgear, LV switchgear), height of substation room/HV switch room/LV switch room shall also take into account requirement of space for turning radius of cable above the equipment height.

gg) All the rooms shall be provided with partitions up to the ceiling and shall have proper ventilation. Special care should be taken to dissipate transformer heat and where necessary fresh air louvers at lower level and exhaust fans at higher level shall be provided at suitable locations.

hh) In case of cable trench in substation/HV switch room/LV switch room, the same shall be adequately drained to ensure no water is stagnated at any time with live cables.

jj) *Power supply to emergency fire and life safety systems* — Emergency power supply of distribution system for critical requirement for functioning of fire and life safety system and equipment, shall be planned for efficient and reliable power and control supply to the following systems and equipment where provided:

  1) Fire pumps;
  2) Pressurization and smoke venting; including its ancillary systems such as dampers and actuators;
  3) Fireman's lifts (including all lifts).
  4) Exit signage lighting;
  5) Emergency lighting;
  6) Fire alarm system;
  7) Public address (PA) system (relating to emergency voice evacuation and annunciation);
  8) Magnetic door hold open devices; and
  9) Lighting in fire command control and security room.

Power supply to these systems and equipment shall be from normal and emergency (standby generator) power sources with change over facility. It shall be ensured that in case the power supply is from HT source/HT generation, transformers should be planned in stand-by capacity to ensure continuity of power to such systems. Wherever transformers are installed at higher levels in buildings and backup DG sets are of higher voltage rating, then dual redundant cables shall be taken to all transformers. The generator shall be capable of taking starting current of all the fire and life safety systems and equipment as above. Where parallel HV/LV supply from a separate substation fed from different grid is provided with appropriate transformer for emergency, the provision of generator may be waived in consultation with the Authority.

NOTE — Standby generator shall not be kept at upper levels, *see* **4.3.1**.

The power supply to the panel/distribution board of these fire and life safety systems shall be through fire proof enclosures or fire survival cables or through alternate route in the adjoining fire compartment to ensure that supply of power is reliable to these systems and equipment. It is to be ensured that the cabling from the adjoining fire compartment is to be protected within the compartment of vulnerability.

The location of the panel/distribution board feeding the fire and life safety system shall be in fire safe zone ensuring supply of power to these systems. The cable used shall as far as possible be fire survival cable as per the accepted standard [D-2(3)].

Cables for fire alarm and PA system shall be laid in metal conduits or armoured to provide physical segregation from the power cables.

NOTE — Fire control room to be located at or near the main entrance of the building which shall be treated as fire safe zone for all purposes.

kk) Other requirements as given in *Central Electricity Authority* (*Measures relating to Safety and Electric Supply*) *Regulations*, 2023 shall also be complied with. The fire safety requirements for substation and electrical rooms, including fire rating requirements of substations enclosure, that is, walls, floor, ceiling, openings, doors, etc, as given in Part F 'Fire and Life Safety' of this NBCS should also be complied with.

4.2.2 *Layout of Substation*

4.2.2.1 In allocating the area of substation, it is to be noted that the flow of electric power is from supply company's meter room to HV room, then to transformer and finally to the LV switchgear room. The layout of the room and trenches of required depth shall be in accordance with this flow, so as to optimize the cables, bus-trunking, etc. Visibility of equipment controlled from the operating point of the controlling switchgear is also a desirable feature, though it may not be achievable in case of large substations. Substations shall not be located at or across expansion joints. The rooms/spaces required in a substation shall be provided as below (*see also* Fig. 1):

a) *Supply company's meter room*, generally at the periphery of the premise with direct access from the road/outside;

b) *HV isolation room*, required in case the substation is away from the meter room and is planned adjacent to meter room for disconnecting supply in case of any repair required between meter room and substation;

c) *HV panel room/space*, located adjacent to transformer;

d) *Transformer room/space*, separate space in case of oil-filled transformer and combined space in case of dry type transformer;

e) *LV isolation room/space* required, in case LV panel is away from transformer or on a different level for isolating supply in case of any repair required between transformer and LV switchgear; and

f) *Main LV panel room/space*, required for distribution to different facility/utility in a building.

A typical layout of a substation is shown in Fig. 1B.

FIG. 1 TYPICAL LAYOUT OF SUBSTATION INCLUDING MINIMUM RECOMMENDED SPACING OF TRANSFORMER PERIPHERY FROM WALLS

4.2.2.2 *Capacity and size of substation*

The capacity of a substation depends upon the area of the building and its type. The capacity of substation may be determined based on the load requirements [*see also* 3.5.2 (g)]. The Annex F of **6.5.1** under Part 1 'General and Common Aspects, Section 9 Wiring Installations' of good practice [D-2(1)] gives broad values for different types of loads. Ratings of some electrical equipment are given in **6.1**. The Table given below provides broad values for different types of electrical loads. All these aspects shall be considered while calculating the load assessment for the building.

Sl No.	*Purpose of Final Circuit Fed from Conductors or Switchgear to which Diversity Applies*	*Typical Allowances for Diversity Based on*: *Type of Building*		
		Individual House-Hold Installations, Including Individual Dwelling of a Block	Small Shops, Stores, Offices and Business Premises	Small Hotels, Boarding Houses, etc
(1)	(2)	(3)	(4)	(5)
i)	Lighting and convenience power	66 percent of total current demand	90 percent of total current demand	75 percent of total current demand
ii)	Heating and power [*see also* Sl No. (iii) to (iv)]	100 percent of total current demand up to 10 A + 50 percent of any current demand in excess of 10 A	100 percent of full load of largest appliance + 75 percent of remaining appliances	100 percent of full load of largest appliance + 60 percent of second largest appliance + 40 percent of remaining appliances
iii)	Air-conditioning (non-centralized)	100 percent of connected AC load for spaces up to 100 m^2 and 60 percent to 75 percent of connected AC load beyond 100 m^2	100 percent of connected AC load for spaces up to 200 m^2 and 80 percent to 85 percent of connected AC load beyond 200 m^2	90 percent of full load for public spaces and FOTH/BOTH spaces + 60 percent – 75 percent of rooms
iv)	Air-conditioning (centralized)	70 percent of high side equipment and 80 percentage of low side equipment	80 percent of high side equipment and 90 percentage of low side equipment	80 percent of high side equipment and 90 percentage of low side equipment
v)	Cooking appliances	10 A + 30 percent full load of connected cooking appliances in excess of 10 A + 6 A if socket-outlet incorporated in the unit	100 percent of full load of largest appliance + 80 percent of full load of second largest appliance + 60 percent of full load of remaining appliances	70 percent to 60 percent of full load of kitchen equipment and its corresponding ventilation equipment
vi)	Laundry equipment’s	100 percent of full load of largest motor + 50 percent of full load of remaining motors	100 percent of full load of largest motor + 50 percent of full load of remaining motors	100 percent of full load of largest motor + 50 percent of full load of remaining motors
vii)	Motors (other than lift, escalators and travellators motors which are subject to special consideration)	100 percent of full load of largest motor + 50 percent of full load of remaining motors	100 percent of full load of largest motor + 80 percent of full load of second largest motor + 60 percent of full load of remaining motors	100 percent of full load of largest motor + 50 percent of full load of remaining motors

Table (*Concluded*)

Sl No.	*Purpose of Final Circuit Fed from Conductors or Switchgear to which Diversity Applies*	*Typical Allowances for Diversity Based on*: *Type of Building*		
		Individual House-Hold Installations, Including Individual Dwelling of a Block	Small Shops, Stores, Offices and Business Premises	Small Hotels, Boarding Houses, etc
(1)	(2)	(3)	(4)	(5)
viii)	Lift, escalators and travellators	100 percentage of cumulative loads	100 percentage of cumulative loads	100 percentage of cumulative loads
ix)	Water heater/heat pump (instantaneous type[1])	100 percent of full load of largest appliance + 100 percent of full load of second largest appliance + 25 percent of full load of remaining appliances	100 percent of full load of largest appliance + 100 percent of full load of second largest appliance + 25 percent of full load of remaining appliances	100 percent of full load of largest appliance + 100 percent of full load of second largest appliance + 25 percent of full load of remaining appliances
x)	Water heater (thermostatically controlled)	No diversity allowable[2]	–	–
xi)	Floor warming installations	No diversity allowable[2]	–	–
xii)	Water heaters thermal storage space heating installations	No diversity allowable[2]	–	–
xiii)	Standard arrangements of final circuits in accordance with good practice [D-2(18)]	100 percent of the current demand of the largest circuit + 40 percent of the current demand of every other circuit	100 percent of the current demand of the largest circuit + 50 percent of the current demand of every other circuit	100 percent of the current demand of the largest circuit + 40 percent of the current demand of every other circuit
xiv)	Socket-outlets other than those included in Sl No. (ix) and stationary equipment other than those listed above	100 percent of the current demand of the largest point + 40 percent of the current demand of every other point	100 percent of the current demand of the largest point + 75 percent of the current demand of every other point	100 percent of the current demand of the largest point + 75 percent of the current demand of every point in main rooms (dining rooms, etc) + 40 percent of the current demand of every other point

NOTE — Diversity may be considered if multiple units of water heater are there in an individual house-hold installation, including individual dwelling of a block.

---

[1] For the purpose of the table, an instantaneous water heater is deemed to be a water heater of any loading which heats water only while the tap is turned on and therefore uses electricity intermittently.

[2] It is important to ensure that the distribution boards are of sufficient rating to take the total load connected to them without the application of any diversity.

After calculating the electrical load on the above basis, an overall load factor of 50 percent to 90 percent is to be applied to arrive at the minimum capacity of substation. A future load may also be considered for substation sizing [*see* **3.5.2** (g)]. The area required for substation and transformer room for different capacities is given in Annex C for general guidance. For reliability, it is recommended to split the load into more than one transformer and also provide for standby transformer as well as multiple sources, bus-section, etc.

4.3 Emergency Power Backup System (DG Sets/Gas Generators)

4.3.1 *Location*

The emergency power supply (such as generating sets) should not be allowed to be installed above ground floor or below the first basement level of the building in case of multiple basements. However, if necessary DG set can be installed in first floor with dedicated approach and in separate fire compartment. In case of DG set located in basement, facilities for forced ventilation shall be provided such that there is minimum derating of the equipment. The generating set should preferably be housed adjacent to LV switchgear in the substation building to enable transfer of electrical load efficiently and also to avoid transfer of vibration and noise to the main building.

4.3.2 *Room for Emergency Power Backup System*

The capacity of standby generating set shall be chosen on the basis of essential light load, essential air conditioning load, essential life and safety services load [*see* **4.2.1**(jj)], essential equipment load and essential services load, such as minimum one lift out of the bank of lifts and minimum one or all water pumps. In certain cases, more than one generating set is provided based on the type of essential and sensitive loads that are to be operational during power breakdowns. Hence depending on the change over time, the connected switchgears/automatic mains failure (AMF) panels are to be selected. Having chosen the capacity and number of generating sets, required space may be provided for their installation (*see* Annex D for general guidance). There shall be provision of separate direct escape and entry from outside so that in case of fire, electrical supplies can be disconnected to avoid additional losses which may be caused due to electrical supply, present at the time of fire. The height of diesel generating (DG) set rooms shall however be not more than 3 000 mm above the DG set height, unless required due to DG room ventilation requirements. Adequate space shall be provided for storing of fuel. Facilities including space at appropriate positions, relative to the location of the installed equipment has to be kept in the layout design for removal of equipment or sub-assemblies for repair or maintenance. When it is located at a place, other than the ground level with direct equipment access, a hatch or ramp shall be provided.

4.3.3 *Installation and Other Requirements*

Following installation and other requirements shall also be complied with:

a) Day-oil tanks for the DG sets shall be in compliance with *The Petroleum Act*, 1934. It is desirable to have day oil tanks of capacity less than 1 000 litre of diesel/high speed diesel (HSD) with the DG set and not exceeding 1 500 litre of HSD in separate rooms adjacent to DG sets/DG room. Additional quantities required should be kept in underground tanks as per provisions of *The Petroleum Act*, 1934 after taking necessary license;

b) The emergency installation shall comply with the norms laid down by the Central Pollution Control Board (CPCB) and shall also be in compliance with *The Petroleum Act*, 1934 and guidelines of Oil Industry Safety Directorate (OISD). Compartmentation for fire protection with detection and first-aid protection measures is essential;

   NOTE — Different type of fire safety requirements exists for the DG set, for the oil storage area and for the switchgear (*see also* Part F 'Fire and Life Safety' of this NBCS).

c) Acoustic enclosure for DG sets/acoustic lining of the DG room and ventilation system for DG room shall be in line with the requirements of CPCB. If DG set is located outdoor, it shall be housed in acoustics enclosure as per the requirements of CPCB norms. For acoustical enclosures/treatment, reference shall also be made to Part D 'Building Services, Section 4 Acoustics, Sound Insulation and Noise Control' of this NBCS;

d) Vertical stacking of DG Sets should not be done to ensure at least one DG set is in operation when the other set is on fire or under maintenance. In case stacking of DG sets is unavoidable on ground, a proper fire barrier of 120 min fire rating between the two DG sets should be ensured. Both DG sets should be kept on free standing civil structure with independent access for each generating set and fire barriers in between, such that fire in one does not jump/drip to other. Also, both should be available independently for repair and maintenance. In case of horizontal stacking of DG sets not less than 1.2 m space between the DG sets shall be maintained. Proper ventilation arrangement within the space shall be provided where stacking of DG sets is done;

e) The DG set room should have proper ventilation for engine combustion requirements, heat produced by the body of DG set and the heat removal from radiator or cooling tower, etc to maintain ambient temperature inside the room. The other requirements given in Part F 'Fire and Life Safety' of this NBCS for room for emergency power backup system including DG set room should also be complied with;

f) Other environmental requirements under the provisions of *The Petroleum Act/Rules*, 2002 and norms laid down by CPCB, as amended from time to time, shall be taken into account particularly from the aspect of engine emissions including the height of exhaust pipe and permitted noise levels/controls; and

g) Provisions contained in the *CEA* (*Measures relating to Safety and Electric Supply*) *Regulations*, 2023, as amended up to date, good practice [D-2(1)] and relevant Indian Standards shall also be complied with.

4.4 Battery Storage Energy Power Backup System (Li-ion or Similar)

Bulk storage of batteries for power backup supply shall be allowed to be installed in rooms which are properly ventilated to avoid fire accidents (18 air changes per hour). The system shall comply with provisions under relevant IEC standards for storage batteries. There shall be proper space around the container having storage batteries. Necessary gas monitoring system with automatic ventilation arrangement shall be provided for the space. No other material shall be stored in the battery storage area. These batteries should be properly maintained and connected to avoid any sparking/flashing leading to fire. Protection measures shall be taken to avoid thermal runaway, short circuiting, overheating of connecting cables, etc. Container should be air-conditioned/air cooled/liquid cooled and kept as per OEM guidelines. All protection and safety measures as given in the relevant Indian Standards shall be complied. Only a.c. wiring should be taken out of the container for synchronizing with other emergency sources or feeding solar power to premise as individual supply.

4.5 Multiple Energy Sources

When multiple energy sources such as grid, DG set power backup with AMF panel, battery storage energy system, on grid solar PV power, on grid other renewable energy sources such as wind power, micro wind wheel, etc are to be used in the same project simultaneously, synchronization of voltage and frequency of each source is required for energies to be used optimally including setting priorities of source utilization. All protection and safety measures as given in the relevant Indian Standards for each of the energy sources shall also be complied with.

4.6 Location of LV Switch Room Other Than in Substation

In large installations other than where a substation is provided, a separate switch room shall be provided. This shall be located as close to the electrical load centre as possible, on the ground floor or on the first basement level of the building, preferably on the same floor as Transformers. In case LT panel and transformer and DG sets are on different floors then LT isolators shall be proposed adjacent to transformer and DG sets.

Suitable cable trays/busducts shall be laid with minimum number of bends from the points of entry of the main supply cable to the position of the main switchgear. The switch room shall also be placed in such a position that riser shafts may readily be provided therefrom to the upper floors of the building in one straight vertical run. In larger buildings, more than one riser shaft may be required and then horizontal cable trays/bus ducts may also be required for running cables from the switch room to the foot of each rising main. The support system shall be sufficient to take into account the load of the cables to be carried with seismic considerations.

Such cable trays shall either be reserved for specific voltage grades or provided with a means of segregation for low and extra low voltage installations, such as nurses call-bell systems in hospitals, intercom telephone installations, fire detection and alarm system, security systems, data cables and announcement or public address system. Cables/wires for emergency fire and life safety services and their routing should be in accordance with **4.2.1**(jj) and Part F 'Fire and Life Safety' of this NBCS so that these services are maintained even in the event of fire.

Clear space around panels should be kept for access and maintenance depending on circuit breaker type as required. In case of ACB/MCCB front and back access should be planned with all sides movement clearance with 1 000 mm access on back and sides and 2 000 mm access in front of panel. However, space of less than or up to 200 mm is permitted on the back of the panel where there is no access or sufficient space.

4.7 Location and Requirements of Distribution Panels

All distribution panels including switchgears shall be installed in readily accessible position. The electrical controlgear distribution panels and other apparatus, which are required on each floor may conveniently be mounted adjacent to the rising mains, and adequate space considering clearances required as per **5.3.6.8** shall be provided at each floor for this purpose.

4.8 Substation Safety

The owner and the operator of any substation shall be collectively and severally be responsible for any lapse or neglect leading to an accident or an incidence of an avoidable abnormality and shall take care of the following safety requirements:

a) Enclose the substation or similar equipment where necessary to prevent, so far as is reasonably practicable, danger of electric shock or unauthorized access.

b) All equipment, entry and exit shall be always kept accessible.

c) Substation should be a separate fire compartment and its ventilation should be independent of any other fire compartment.

d) All substation rooms shall have two doors at opposite ends. Distance between all equipment such that exit/entry of equipment is feasible without removing of any equipment, light, cable or bus duct, etc.

e) Any part of the substation which is open to the air shall be enclosed, with a fence (earthed efficiently at both ends) or wall at least 600 mm above the height of tallest equipment; to prevent, so far as is reasonably practicable, danger of electric shock or unauthorized access.

f) Transformers (oil filled) when placed in open shall have fencing/wall at least 600 mm above the height of transformer. If trees are there around the substation, then a temporary cover should be provided to avoid leaves falling on the terminals of HT/LT terminations.

g) It shall be ensured that the following are displayed at all times in the substation:

    1) Sufficient safety signs of such size and placed in such positions as are necessary to give due warning of such danger as is reasonably foreseeable in the circumstances;

    2) A notice which is placed in a conspicuous position and which gives the location or identification of the substation, the name of each owner/operator who owns or operates the substation equipment making up the substation and the telephone number where a suitably qualified person appointed for this purpose by the owner/operator will be in constant attendance; and

    3) Such other signs, which are of such size and placed in such positions, as are necessary to give due warning of danger having regard to the siting of, the nature of, and the measures taken to ensure the physical security of, the substation equipment;

h) All reasonable precautions are taken to minimize the risk of fire associated with the equipment.

j) In addition to provisions mentioned in (c), name and emergency telephone number of the authorized personnel shall also be displayed at the substation and instructions covering schematic diagram; requirements of switchgear interlocking, if any; and permission requirements, if any, for load limitations on (incoming) feeders; be also prominently displayed.

4.9 Overhead Lines, Wires and Cables

All erections/alterations having relation to overhead lines, wires and cables shall comply with *Central Electricity Authority* (*Measures relating to Safety and Electric Supply*) *Regulations*, 2023 with special reference to regulation number 62 and 63 and the following points. However, in case of any conflict, the regulations shall prevail (*see* Annex B).

4.9.1 *Height Requirement*

4.9.1.1 While overhead lines may not be relevant within buildings, regulations related to overhead lines are of concern from different angles as follows:

a) Overhead lines may be required in building complexes, though use of underground cables is the preferred alternative; and

b) Overhead lines may be passing through the site of a building. In such a case the safety aspects are important for the construction activity in the vicinity of the overhead line as well as portions of low height buildings that may have to be constructed below the overhead lines. Overhead lines running adjacent to buildings pose hazard from the aspect of certain maintenance activity (such as use of a ladder on external face of a building) causing temporary compromise of the minimum safety clearance.

4.9.1.2 If at any time subsequent to the erection of an overhead line, whether covered with insulating material or not, or underground cable, any person who proposes to erect a new building or structure or to raise any road level or to carry out any other type of work whether permanent or temporary or to make in or upon any building, or structure or road, any permanent or temporary addition or alteration, in proximity to an overhead line or underground cable, such person and the contractor whom he employs to carry out the erection, addition or alteration, shall give intimation in writing of his intention to do so to the supplier or owner and to the Electrical Inspector and shall furnish therewith a scale drawing showing the proposed building, structure, road or any addition or alteration and scaffolding thereof required during the construction. In this connection, Regulation 63 of *Central Electricity Authority* (*Measures relating to Safety and Electric Supply*) *Regulations*, 2023, shall also be complied with (*see* Annex B).

4.9.1.3 Any person responsible for erecting an overhead line will keep informed the authority(s) responsible for services in that area for telecommunication, gas distribution, water and sewage network; roads and so as to have proper coordination to ensure safety. He shall also publish the testing, energizing programme for the line in the interest of safety.

4.9.1.4 For minimum distance (vertical and horizontal) of electric lines/wires/cables from buildings, Regulations 60, 62, 63, and 67 of *Central Electricity Authority* (*Measures relating to Safety and Electric Supply*) *Regulations*, 2023, shall be complied with (*see* Annex B).

4.9.1.5 Regulation 66 of *Central Electricity Authority* (*Measures relating to Safety and Electric Supply*) *Regulations*, 2023, which govern conditions related to the storage of material including storage of construction material at a construction site, or other materials in a building in vicinity of overhead lines and underground cables, shall also be complied with (*see* Annex B).

4.9.2 *Position, Insulation and Protection of Overhead Lines*

4.9.2.1 Any part of an overhead line which is not connected with earth and which is not ordinarily accessible shall be supported on insulators or surrounded by insulation. Any part of an overhead line which is not connected with earth and which is ordinarily accessible shall be:

a) made dead; or

b) so insulated that it is protected, so far it is reasonably practicable, against mechanical damage or interference; or

c) adequately protected to prevent danger.

4.9.2.2 Any person responsible for erecting a building or structure which will cause any part of an overhead line which is not connected with earth to become ordinarily accessible shall give reasonable notice to the licensee or distributor who owns or operates the overhead line of his intention to erect that building or structure.

The expression ‘ordinarily accessible’ means the overhead line might be reachable by hand if any scaffolding, ladder or other construction was erected or placed on/in, against or near to a building or structure.

4.9.2.3 Any bare conductor not connected with earth, which is part of a low voltage overhead line, shall be situated throughout its length directly above a bare conductor which is connected with earth.

4.9.3 *Precautions against Access and Warnings of Dangers*

4.9.3.1 Every support carrying a high voltage overhead line shall be fitted with anti-climbing devices to prevent any unauthorized person from reaching a position at which any such line will be a source of danger. In this connection, Regulation 76 of *Central Electricity Authority* (*Measures Relating to Safety and Electric Supply*) *Regulations*, 2023, shall also be complied with (*see* Annex B).

4.9.3.2 Every support carrying a high voltage overhead line, and every support carrying a low voltage overhead line incorporating bare phase conductors, shall have attached to it sufficient safety signs and placed in such positions as are necessary to give due warning of such danger as is reasonably foreseeable in the circumstances.

4.9.3.3 Poles supporting overhead lines near the road junctions and turnings shall be protected by a masonry or earth fill structure or metal barricade, to prevent a vehicle from directly hitting the pole, so that the vehicle, if out of control, is restrained from causing total damage to the live conductor system and lead to a hazardous condition on the road or footpath or building.

4.9.4 *Fitting of Insulators to Stay Wires*

Every stay wire which forms part of, or is attached to, any support carrying an overhead line incorporating bare phase conductors (except where the support is a lattice steel structure or other structure entirely of metal and connected to earth) shall be fitted with an insulator, no part of which shall be less than 3 m above ground or above the normal height of any such line attached to that support.

4.10 Maps of Underground Networks

4.10.1 Any person or organization or authority laying cables shall contact the local authority in charge of that area and find out the layout of:

a) water distribution pipe lines in the area;
b) sewage distribution network;
c) telecommunication network;
d) gas pipeline network; and
e) existing power cable network;

and plan the cable network in such a manner that the system is compatible, safe and non-interfering either during its installation or during its operation and maintenance. Plan of the proposed cable installation shall be brought to the notice of the other authorities referred above.

4.10.2 Suitable cable markers and danger sign as will be appropriate for the safety of the workmen of any of the systems shall be installed along with the cable installation. Cable route markers shall be provided at every 20 m and also at turnings and/or crossings.

4.10.3 Notification of testing and energization of the system shall also be suitably publicized for ensuring safety.

4.10.4 Any person or organization or authority associated with the operation and maintenance of services in a complex is required to have a complete integrated diagram or drawings of all services with particular emphasis on the hidden pipes, cables, etc, duly kept up-to-date by frequent interaction with all agencies associated with the maintenance work.

Organization or agency responsible for laying cables shall have and, so far it is reasonably practicable, keep up-to-date, a map or series of maps indicating the position and depth below surface level of all networks or parts thereof which he owns or operates. Where adequate mapping has not been done and the excavation for cable laying reveals lines pertaining to any of the other services, three dimensional location should be marked and recorded. Even where mapping exists, it may be examined if the records have become obsolete due to change such as, in road level. Any map prepared or kept shall be available for inspection by any authority, such as municipality, water supply, sewage, service providers and general public, provided they have a reasonable cause for requiring reference to any part of the map.

4.10.5 Any agency working on any one or more service (occupying the underground space for service pipes, cables, etc) should keep the other agencies informed of the work so that an inadvertent action will not cause a disruption of service. Each agency should be responsible for keeping the latest information with the central authority of such records and should be responsible to ensure that the modifications, if any, are duly updated and notified among the other agencies.

5 DISTRIBUTION OF SUPPLY AND CABLING

5.1 General

5.1.1 In the planning and design of an electrical wiring installation, due consideration shall be made of all the prevailing conditions. It is recommended that advice of a competent electrical engineer be sought at the initial stage itself with a view to providing an installation that will prove adequate for its intended purpose, be reliable, safe and efficient.

While planning of routing of cables and bus trunking it shall be ensured to avoid passing of cables and bus trunking from lift lobbies, staircase lobbies and fire exits. Proper ventilations or air-changes shall be provided for heat rejected from bus trunking and cables.

5.1.2 A certain redundancy in the electrical system is necessary and has to be built in from the initial design stage itself. The extent of redundancy will depend on the type of load, its criticality, normal hours of use, quality of power supply in that area, coordination with the standby power supply, capacity to meet the starting current requirements of large motors, etc.

5.1.3 In modern building technology, following high demands are made of the power distribution system and its individual components:

a) long life and good service quality;

b) safe protection in the event of fire;

c) low fire load;

d) flexibility in load location and connection, but critical in design;

e) low space requirement; and

f) minimum effort involved in carrying out retrofits.

5.1.4 The high load density in modern large buildings and high-rise buildings demands compact and safe solution for the supply of power. The use of busbar trunking system is ideal for such applications. Busbar trunking can be installed in vertical riser’s shafts or horizontally in passages for transmission and distribution of power. They allow electrical installations to be planned in a simple and neat manner. In the building complexes, additional safety demands with respect to fire barriers and fire load can also be met with the use of busbar trunking. Busbar trunking system also reduces the combustible material near the area with high energy in comparison with other distribution systems such as cables and makes the building safe from the aspect of vulnerability to fire of electrical origin. In addition, unlike cable systems the reliability of a busbar trunking system is very high. These systems also require very little periodic maintenance. Choice of busbar trunking for distribution in buildings can be made on the basis of:

a) reduced fire load (drastically reduced in comparison to the cable system);

NOTE — Insulation materials of cables are required to be fire resistant and an essential performance requirement is that the insulation material may burn or melt and flow when directly exposed to a temperature (or fire) higher than what it is class designated, but should not continue to burn after the flame or the source of heat or fire is extinguished. Even if the above fire resistant property is exhibited by the cable insulation, a large collection of cables will make the cable insulation fail to exhibit this retardant property. While specific guidelines for limiting number of cable and bunching is not available and in such cases the switch over to a busbar trunking system is the proper alternative.

b) reduced maintenance over its entire lifetime;

c) longer service lifetime in comparison with a cable distribution; and

d) enhanced reliability due to rigid bolted joints and terminations and extremely low possibility of insulation failure.

NOTE — Provisions contained in electric supply and cabling shall also comply with the provisions relating to *the CEA* (*Measures relating to Safety and Electric Supply*) *Regulations*, 2023, good practice [D-2(1)] and relevant Indian Standards as amended up to date.

5.2 System of Supply

5.2.1 All electrical apparatus shall be suitable for the voltage and frequency of supply.

5.2.2 In case of connected load of 100 kVA and above, the relative advantage of high voltage three-phase supply may be considered. Though the use of high voltage supply entails the provisions of space and the capital cost of providing suitable transformer substation at the consumer's premises, the following advantages are gained:

a) advantage in tariff;

b) more effective earth fault protection for heavy current circuits;

c) elimination of interference with supplies to other consumers permitting the use of large size motors, welding plant, etc; and

d) better control of voltage regulation and more constant supply voltage.

NOTE — Additional safety precautions required to be observed in HV installations shall also be kept in view.

In many cases there may be no choice available to the consumer, as most of the licensees have formulated their policy of correlating the supply voltage with the connected load or the contract demand. Generally, the supply is at 240 V single phase up to 5 kVA, 415/240 V 3 phase from 5 kVA to 100 kVA, 11 kV (or 22 kV) for loads up to 5 MVA and 33 kV for consumers of connected load or contract demand more than 5 MVA.

In case of load exceeding 10 MVA at 33 kV for building complex, designer may explore option of having a combination of power transformers and distribution transformers to reduce the numbers and long lengths of power cables. 33 kV/11 kV power substation at site level/utility building for stepping down at 11 kV and then having 11 kV/415 Volt distribution substation at basement/ground/first floor/usage floors, near load centres to avoid long lengths of 415 volt cables.

5.2.3 In very large industrial buildings where heavy electric demands occur at scattered locations, the economics of electrical distribution at high voltage from the main substation to other subsidiary transformer substations or to certain items of plant, such as large motors and furnaces, should be considered. The relative economy attainable by use of high voltage distribution and high voltage equipment is a matter for expert judgment and individual assessment in the light of experience by a professionally qualified electrical engineer. *See also* good practice [D-2(1)] and accepted standard [D-2(19)].

5.2.4 In case of complex buildings/mixed use buildings where individual load of usage category (such as commercial, mercantile, residential, hotels, hospitals, storage, industry, etc has cumulative load of 1 000 kVA, then for EV charging requiring more than 100 kVA power should be proposed with independent distribution transformer(s) (200 kVA or more) with separate meter to avoid mixing of different type of loads, harmonics, etc.

5.2.5 As far as possible, EV charging arrangement shall be provided with independent transformer to ensure that harmonics created during EV charging do not interfere with power supply to other system. It shall be ensured that EV charging is not fed from diesel generator sets or gas generators or similar fuel based power generating systems (*see* **10.7** for more details).

5.3 Substation Equipment and Accessories

Substations require an approval from the Electrical Inspectorate. Such approval is mandatory before energizing the substation. Therefore, it is essential to get the approval for the general layout, schematic layout, protection plan, etc, before the start of the work from the Inspectorate. All substation equipment and accessories and materials, etc, shall conform to relevant Indian Standards, wherever they exist, otherwise the consumer (or his consultant) shall specify the standards to which the equipment to be supplied and that shall be approved by the authority. Manufacturers of equipment have to furnish certificate of conformity as well as type test certificates for record, in addition to specified test certificates for acceptance tests and installation related tests for earthing, earth continuity, load tests and tests for performance of protective gear. All works under this, shall comply with the requirements of relevant Indian Standards and provisions of **5.1** of Part 1 'General and Common Aspects, Section 9 Wiring Installations' of good practice [D-2(1)].

5.3.1 *Supply Company's High Voltage Meter Board*

In case of single point high voltage metering, energy meters shall be installed in building premise as per **4.2.2.1**, at such a place which is readily accessible/provides unobstructed access to the electric supply company. The supplier or owner of the installation shall provide at the point of commencement of supply a suitable isolating device fixed in a conspicuous position at not more than 1.7 m above the ground so as to completely isolate the supply to the building in case of emergency.

In case of multipoint metering, main energy meter and reference meters shall be installed in building premises as per **4.2.2.1**, at a place which is readily accessible to the owner/operator of the building and the authority. These should be accompanied with smart metering system (with dual source pre-paid meters).

In this connection, the *Central Electricity Authority* (*Installation and Operation of Meters*) *Regulations*, 2006, as amended from time-to-time shall also be complied with.

5.3.2 *High Voltage Switchgear*

5.3.2.1 The selection of the type of high voltage switchgear for any installation inter alia depends upon the following:

a) voltage of the supply system;

b) prospective short-circuit current at the point of supply;

c) size and layout of electrical installation;

d) availability of space; and

e) nature of installation.

Making and breaking capacity of switchgear shall be commensurate with short-circuit potentialities of the supply system and the supply authority shall be consulted on this subject. The HV switchgear and controlgear shall conform to the relevant Indian Standards. For details see accepted standard [D-2(7)].

5.3.2.2 Guidelines on various types of switchgear equipment and their choice for a particular application shall be in accordance with good practice [D-2(20)].

5.3.2.3 In extensive installations of switchgear (having more than four incoming supply or having more than 12 circuit breakers), banks of switchgears shall be segregated from each other in order to prevent spreading of the risk of damage by fire or explosion arising from switch failure. Where a bus-bar section switch is installed, it shall also be segregated from adjoining banks in the same way {*see* good practice [D-2(21)]}.

5.3.2.4 It should be possible to isolate any section from the rest of the switchboards such that work might be undertaken on this section without the necessity of making the switchboard dead. Isolating switches used for the interconnection of sections or for the purpose of isolating circuit-breakers of other apparatus, shall also be segregated within its compartment so that no live part is accessible when work in a neighbouring section is in progress.

5.3.2.5 In the case of double or ring main supply, switchgears with interlocking arrangement shall be provided to prevent simultaneous switching of two different supply sources. Electrical and/or mechanical interlocks may preferably be provided.

5.3.2.6 The selection and erection shall also comply with the provisions of accepted standard [D-2(22)].

5.3.3 *HV Cables*

5.3.3.1 The sizing of the cable shall depend upon the method of laying cable, current to be carried, permissible maximum temperature it shall withstand, voltage drop over the length of the cable, the prospective short-circuit current to which the cable may be subjected, the characteristics of the overload protection gear installed, load cycle, thermal resistivity of the soil and the operating voltage {*see also* good practice [D-2(23)]}.

5.3.3.2 All HV cables shall be installed in accordance with good practice [D-2(23)]. The HV cables shall either be laid on the cable rack/built-up concrete trenches/tunnel/basement or directly buried in the ground depending upon the specific requirement. When HV cable is hanging/running below the basement ceiling slab, the cable shall be laid in a fire rated enclosure/cable tray. The advice of the cable manufacturer with regard to installation, jointing and sealing should also be followed.

5.3.4 *High Voltage Busbar Trunking/Ducting*

HV busbar system is used for transporting power between HV generators, transformers and the infeed main switchgear of the main HV switchgear.

Generally, three types of bus ducts, namely non-segregated, segregated and isolated phase bus ducts are used. The non-segregated bus ducts consist of three phase busbars running in a common enclosure made of steel or aluminium. The enclosure shall provide safety for the operational personnel and shall reduce chances of faults. HV interconnecting busbar trunking for a.c. voltage above 1 kV up to and including 36 kV shall conform to accepted standard [D-2(24)]. The enclosures shall be effectively grounded.

Segregated phase bus ducts are similar to non-segregated phase duct except that metal or isolation barriers are provided between phase conductors to reduce chances of phase to phase faults. However, it is preferable to use metal barriers.

In the case of isolated bus ducts, each phase conductor shall be housed in a separate non-magnetic enclosure. The bus duct shall be made of sections which are assembled together at site to make complete assembly. The enclosure shall be of either round or square shape and welded construction. The enclosures of all phases in general should be supported on a common steel structure.

Seismic supports shall be provided for busbar trunking having continuous straight lengths of more than 24 m at a single stretch in horizontal formation and 12 m in vertical formation in accordance with relevant standards.

The bus duct system shall be coordinated with connecting switchgear so as to provide adequate protection.

When busbar trunking is crossing different fire compartments, they shall have fire barriers of same rating as that of the compartment (*see also* Part F 'Fire and Life Safety' of this NBCS).

5.3.5 *Transformers*

5.3.5.1 General design objective while selecting the transformer(s) for a substation should be to provide at least two or more transformers, so that a certain amount of redundancy is built in, even if a standby system is provided. With growing emphasis on energy conservation, the system design should be made for both extremes of loading. During the periods of lowest load in the system, it would be desirable to operate only one transformer and subsequently switching on the additional transformers as the load increases during the day. Total transformer capacity is generally selected on the basis of present load, possible future load, operation and maintenance cost and other system conditions. The selection of the maximum size (capacity) of the transformer is guided by the short-circuit making and breaking capacity of the switchgear used in the high voltage distribution system. Maximum size limitation is important from the aspect of feed to a downstream fault. The transformers shall conform to accepted standards [D-2(25)].

5.3.5.2 For reasons of reliability and redundancy it is normal practice to provide at least two transformers (especially where electrical load is beyond 1 500 kVA) for functional buildings, hospitals, hotels, institutes, etc. Providing distribution transformers beyond 1 600 kVA/2 000 kVA is not recommended. Interlinking by tie lines is an alternative to enhance reliability/redundancy in areas where there are a number of substations in close vicinity, such as a campus with three or four multi-storeyed blocks, each with a substation. Ring main type of distribution is preferred for complexes having a number of substations.

5.3.6 *Low Voltage Switchgear*, *Controlgear and their Assemblies*

5.3.6.1 The selection of the type of low voltage switchgear for any installation inter alia depends upon the following:

a) voltage of the distribution system;

b) prospective circuit current at the point at which the switchgear is proposed;

c) prospective short-circuit current at which the switchgear is proposed;

d) availability of space; and

e) nature of installation.

The switchgear, controlgear and their assemblies so selected, shall comply with the accepted standards [D-2(26)].

5.3.6.2 Switchgear (and its protective device) shall have breaking capacity not less than the anticipated fault level in the system at that point. System fault level at a point in distribution systems is predominantly dependent on the transformer size and its reactance. Parallel operation of transformers increases the fault level.

5.3.6.3 Where two or more transformers are to be installed in a substation to supply a low voltage distribution system, the distribution system shall be divided into separate sections each of which shall be normally fed from one transformer only unless the low voltage switchgear has the requisite short-circuit capacity. Provision may, however, be made to interconnect separate sections, through a bus coupler in the event of failure or disconnection of one transformer. *See* **4.2** for details of location and requirements of substation.

5.3.6.4 Isolation and controlling circuit breaker shall be interlocked so that the isolator cannot be operated unless the corresponding breaker is in open condition. The choice between alternative types of equipment may be influenced by the following considerations:

a) In certain installations supplied with electric power from remote transformer substations, it may be necessary to protect main circuits with circuit-breakers operated by earth fault, in order to ensure effective earth fault protection;

b) Where large electric motors, furnaces or other heavy electrical equipment is installed, the main circuits shall be protected from short-circuits by switch disconnector fuse or circuit breakers. For motor protection, the combination of contactor overload device and fuse or circuit breakers shall have total co-ordination at least for motor ratings up to 10 kW and for ratings above 10 kW, it shall be Type 2 co-ordination in accordance with relevant part of accepted standards [D-2(26)]. Wherever necessary, back up protection and earth fault protection shall be provided to the main circuit; and

c) Where means of isolating main circuits is separately required, switch disconnector fuse or switch disconnector may form part of main switchboards.

5.3.6.5 It shall be mandatory to provide power factor improvement at the substation bus with suitable capacity of inductor-capacitor combination and relative switchgear in consultation with the respective manufacturers depending upon the nature of electrical load anticipated on the system. Necessary switchgear/feeder circuit breaker shall be provided for controlling of inductor-capacitor bank.

Power factor of individual motor may be improved by connecting individual capacitor banks in parallel. For higher range of motors, which are running continuously without much variation in load, individual power factor correction at load end is advisable.

NOTE — Care should be taken in deciding the kVAr rating of the capacitor in relation to the magnetizing kVA of the motor. Over rating of the capacitor may cause injury to the motor and capacitor bank. The motor still rotating after disconnection from the supply, may act as generator by self-excitation and produce a voltage higher than supply voltage. If the motor is again switched on before the speed has fallen to about 80 percent of the normal running speed, the high voltage will be superimposed on the supply circuits and will damage both the motor and the capacitor.

As a general rule, the kVAr rating of the capacitor should not exceed the no-load magnetizing kVA of the motor.

Generally, it will be necessary to provide an automatic control for switching on the capacitors matching the load power factor and the bus voltage. Such a scheme will be necessary as capacitors permanently switched in the circuit may cause overvoltage at times of light load. Capacitor panel shall be provided with adequate ventilation facility.

With the wide spread use of thyristor and rectifier based loads, there is a necessity of providing a full size neutral; but this requirement is generally limited to the 3-phase 4-wire distribution generally in the 415 V.

5.3.6.6 Harmonics on the supply systems are becoming a greater problem due to the increasing use of electronic equipment, computer, fluorescent lamps, LEDs and CFLs (both types have control/driver circuits operating in switch mode), mercury vapour and sodium vapour lighting, TV, microwave ovens, latest air conditioners, refrigerators, controlled rectifier and inverters for variable speed drives, power electronics and other non-linear loads. Harmonics may lead to almost as much current in the neutral as in the phases. This current is almost third, fifth, seventh and ninth harmonic. In such cases, phase rectification devices may be considered at the planning stage itself for the limits of harmonic voltage distortion. Use of active filters in combination/independent use with capacitor banks should be proposed with either 3-phase 3-wire or 3-phase 4 wire depending upon the equipment for which electricity is utilized. The active filters along with capacitor panel should be proposed to be located in controlled environment.

5.3.6.7 Sufficient clearances as below shall be provided for isolating the switchboard to allow access for servicing, testing and maintenance (*see* Fig. 2):

a) A clear space of not less than 1 m in width shall be provided in front of the switchboard;

NOTE — In case the board has a shutter in the front for aesthetic reasons, the opening of the shutter shall satisfy the requirement of working/safety space of 1 m in front of the switchgear.

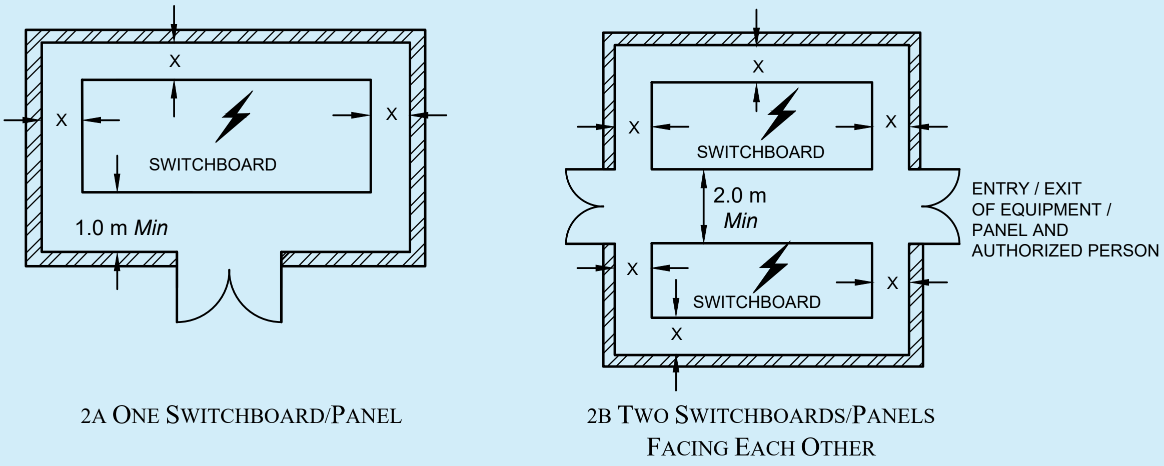
b) If access behind the switchboard is provided then it shall be either less than 200 mm or more than 750 mm in width, measured from the farthest protruding part of any attachment or conductor;

c) If the space behind the switchboard exceeds 750 mm in width, there shall be a passageway from either end of the switchboard, clear to a height of 1.8 m; and

d) If two switchboards are facing each other, a minimum distance of 2.0 m shall be maintained between them.

The connections between the switchgear mounting and the outgoing cable up to the wall shall be enclosed in a protection pipe.

There shall be a clear distance of not less than 250 mm between the board and the insulation cover, the distance being increased for larger boards in order that on closing of the cover, the insulation of the cables is not subjected to damage and no excessive twisting or bending in any case. The cable alley in the metal board should enable within prescribed limit, twisting or bending of cable such that insulation of the cables is not subjected to damage.



2A ONE SWITCHBOARD/PANEL

2B TWO SWITCHBOARDS/PANELS FACING EACH OTHER

X = LESS THAN 200 mm (IF SWITCHBOARD/PANEL IS NOT ACCESSIBLE FROM BEHIND)
= MORE THAN 750 mm (IF SWITCHBOARD/PANEL IS ACCESSIBLE FROM BEHIND)

NOTE — X TO BE MEASURED FROM THE FARTHEST PROTRUDING PART OF ANY ATTACHMENT OR CONDUCTOR.

FIG. 2 CLEARANCES AROUND SWITCHBOARD IN ENCLOSED ROOM

In this connection, for installation of voltages exceeding 250 V single phase, Regulation 37 of *Central Electricity Authority* (*Measures Relating to Safety and Electric Supply*) *Regulations*, 2023 shall also be complied with (*see* Annex B).

5.3.6.8 Sufficient additional space shall be allowed in substations and switch rooms to allow operation and maintenance. Sufficient additional space shall be allowed for temporary location and installation of standard servicing and testing equipment. Space should also be provided to allow for anticipated future extensions.

5.3.6.9 Panels in a room or cubicle, access to which is controlled by lock and key, shall be accessible to authorized persons only.

5.3.6.10 Except main LV panel, it will be preferable to locate the sub-panels/distribution boards/sub-meter boards near load centre. Further, it should be ensured that these panels are easily approachable. The panels should have clear access from common areas excluding staircase.

Where the switchboard is erected in a room of a building isolated from the source of supply or at a distance from it, adequate means of control and isolation shall be provided both near the boards and at the origin of supply. Sufficient clearances as per **5.3.6.8** shall be provided.

5.3.6.11 All switchboards shall be of metal clad totally enclosed type or any insulated enclosed pattern.

5.3.6.12 The selection and erection shall also comply with the provisions of accepted standard [D-2(22)].

5.3.7 *Medium/Low Voltage Cables*

5.3.7.1 The sizing of the cable shall depend upon the current to be carried, method of laying cable, permissible maximum temperature it shall withstand, voltage drop over the length of the cable, the prospective short-circuit current to which the cable may be subjected, the characteristics of the overload protection gear installed, load cycle, thermal resistivity of the soil and the operating voltage {*see also* good practice [D-2(18)]}.

It is desirable to use flame retardant/flame retardant low smoke and halogen free cables and wires in electrical distribution systems.

It is recommended to use four core cable in place of three and half core in respect of sizes below 50 mm^2 to minimize heating of neutral core due to harmonic content in the supply system and to also avoid overload failures. As far as possible, balancing of single phase system shall be done to ensure minimum unbalanced current in neutral of three phase system. Only four core cables shall be used for internal electrical installation. Also, all cable sizes up to 25 mm^2 shall be of copper conductor to prevent overheating and fire incidence in internal electrical installations and capacity/size considerations. All cables shall be installed in accordance with good practice [D-2(18)]. The advice of the cable manufacturer with regard to installation, jointing and sealing should also be followed.

5.3.7.2 *Colour identification of cores of non-flexible cables* {*see also* accepted standard [D-2(27)]}

The colour of cores of non-flexible cables shall be in accordance with the following:

Sl No. (1)	*Function* (2)	*Colour Identification of Core of Rubber of PVC Insulated Non-flexible Cable, or of Sleeve or Disc to be Applied to Conductor or Cable Code* (3)
i)	Protective or earthing	Green and yellow (*see* Note 1)
ii)	Phase of a.c. single-phase circuit	Red [or yellow or blue (*see* Note 2)]
iii)	Neutral of a.c. single or three-phase circuit	Black
iv)	Phase R of 3 phase a.c. circuit	Red
v)	Phase Y of 3 phase a.c. circuit	Yellow
vi)	Phase B of 3 phase a.c. circuit	Blue
vii)	Positive of d.c. 2 wire circuit	Red
viii)	Negative of d.c. 2 wire circuit	Black
ix)	Outer (positive or negative) of d.c. 2 wire circuit derived from 3 wire system	Red
x)	Positive of 3 wire system (positive of 3 wire d.c. circuit)	Red
xi)	Middle wire of 3 wire d.c. circuit	Black
xii)	Negative of 3 wire d.c. circuit	Blue
xiii)	Functional earth-telecommunication	Cream/grey

NOTES

1 Bare conductors are also used for earthing and earth continuity conductors. But it is preferable to use insulated conductors with green coloured insulation with yellow stripes.

2 As alternative to the use of red, if desired in large installations, up to the final distribution board.

3 For armoured PVC-insulated cables and paper-insulated cables, *see* relevant Indian Standard.

5.3.8 *LV Busbar Trunking/Rising Mains*

5.3.8.1 Where heavy loads and/or multiple distribution feeders are required to be supplied, busbar/rising main systems are preferred. The busbars are available for continuous run from point to point or with tap offs at standard intervals and have to be chosen as per specific requirement. Seismic supports shall be provided for busbar trunking having continuous straight lengths of more than 24 m at a single stretch in horizontal formation and 12 m in vertical formation in accordance with relevant standards. There are following two types of LV bus duct system for power distribution:

a) air insulated (conventional) type; and

b) compact and sandwich type.

5.3.8.1.1 *Air insulated* (*conventional*) *type bus duct*

These are used for large power handling between transformer and switchgear or between switchgear and large power loads such as compressor drive motor, etc. This type is generally used in plant rooms, riser shafts, substations, etc. These are generally air insulated with intermediate ceramic support insulators enclosed in a metallic enclosure, which should be earthed. They have the least amount of combustible material. However, when these are crossing different fire compartments, they shall have fire barriers of same rating as that of the compartment (*see also* Part F 'Fire and Life Safety' of this NBCS).

Air insulated (conventional) type bus ducts with non-metallic enclosures are also available. However, such bus ducts shall be used only if essential and with appropriate additional care.

5.3.8.1.2 *Compact and sandwich type bus duct*

Compact and sandwich type bus ducts are used within areas of the building which have space restrictions, functional reasons and for aesthetic considerations. The busbars shall be of copper considering the safety and longevity aspects. They may be used in false ceiling spaces or even in corridors and shafts for distribution without any false ceiling as they provide an aesthetically acceptable finish to merge with other building elements such as beams, ducts or pipes in functional buildings.

The insulation material in such ducts are generally glass fibre tape or epoxy encapsulation in combination with ceramic supports/spacers. These bus ducts should be duly enclosed by a metallic enclosure, which should be earthed.

5.3.8.1.3 The selection and erection shall also comply with the provisions of accepted standard [D-2(28)].

5.3.8.2 The bus duct system shall be coordinated with connecting switchgear so as to provide adequate protection.

5.3.8.3 When busbar trunking is crossing different fire compartments, they shall have fire barriers of same rating as that of the compartment (*see also* Part F 'Fire and Life Safety' of this NBCS).

5.3.8.4 The low voltage busbar trunking shall conform to accepted standard [D-2(28)].

5.4 Reception and Distribution of Main Supply (LV Connections)

5.4.1 *Control at Point of Commencement of Supply*

5.4.1.1 The supplier shall provide a suitable metering switchboard in which each meter units shall have its individual compartment housing meter, wiring, circuit breaker, etc within a consumer's premises, in an accessible position and such metering switchboard shall be contained within adequately enclosed fireproof receptacle. Where more than one consumer is supplied through a common service line, such consumer shall be provided with an independent metering unit in a switchboard housed in common area with an incoming breaker. Such meter switchboards should be housed in an enclosed and lockable space. Cables/wires from such switchboards connecting to individual consumers should terminate directly to consumer's distribution board without any interim termination or change of conductor. Such switchboards maybe located at ground floor or first basement, if building height is not exceeding 15 m. All metering panel/connection arrangements will have interconnection between circuit breakers, fuses, individual meters, etc should be using solid busbar instead of cables (where length of cables is less than 10 m).

However, for buildings above height of 15 m [Regulation 38 of the *Central Electricity Authority* (*Measures relating to Safety and Electric Supply*) *Regulations*, 2023] shall be having meters on individual floors. In case of commercial buildings/shopping malls/multi-use spaces where, combining of units maybe envisaged, meter switchboards should be placed on the floor where consumer unit is located (*see* Annex B).

In case of high rise buildings, the supplier or owner of the installation shall provide at the point of commencement of supply a suitable isolating device with cut-out or breaker to operate on all phases except neutral in the 3 phase, 4 wire circuit and fixed in a conspicuous position at not more than 1.7 m above the ground so as to completely isolate the supply to the building in case of emergency. In this connection, Regulation 38 of *Central Electricity Authority* (*Measures relating to Safety and Electric Supply*) *Regulations*, 2023 shall also be complied with (*see* Annex B).

The supplier in accordance with Regulation 18 of *Central Electricity Authority* (*Measures relating to Safety and Electric Supply*) *Regulations*, 2023 shall provide and maintain on the consumer's premises for the consumer's use, a suitable earth terminal in an accessible position or near the point of commencement of supply as per relevant standards (*see* Annex B).

No cut-out, link or switch other than a linked switch arranged to operate simultaneously on the earthed or earthed neutral conductor and live conductor shall be inserted or remain inserted in any earthed or earthed neutral conductor of a two wire-system or in any earthed or earthed neutral conductor of a multi-wire system or in any conductor connected thereto. This requirement shall however not apply in case of:

a) a link for testing purposes; or

b) a switch for use in controlling a generator or transformer.

In this connection, Regulation 17 (ii) of *Central Electricity Authority* (*Measures Relating to Safety and Electric Supply*) *Regulations*, 2023 shall also be complied with (*see* Annex B).

The neutral shall also be distinctly marked.

5.4.1.2 The main switch shall be easily accessible and situated as near as practicable to the termination of service line.

5.4.1.3 Where the conductors include an earthed conductor of a two-wire system or an earthed neutral conductor of a multi-wire system or a conductor which is to be connected thereto, an indication of a permanent nature shall be provided for identification in accordance with Regulation 17 (i) of *Central Electricity Authority* (*Measures Relating to Safety and Electric Supply*) *Regulations*, 2023 (*see* Annex B).

5.4.1.4 *Energy meters*

5.4.1.4.1 Energy meters conforming to accepted standards [D-2(29)] shall be installed in all buildings at such a place which is readily accessible to the owner/operator/occupant of the building and the Authority. Meters should not be located at an elevated area or a depressed area that does not have access by means of a stairway of normal rise. The height of meter display shall be between 750 mm and 1 800 mm. In case the meter is provided with a secondary display unit, this requirement applies to the secondary display unit only. A minimum clearance of 50 mm should be maintained around the meter itself for better inspection. This includes the space between two meters, between meter and the mounting box and between two mounting boxes as the case may be. The energy meters should either be provided with a protecting covering, enclosing it completely except the glass window through which the readings are noted or should be mounted inside a completely enclosed panel provided with hinged arrangement for locking. Additionally, for outdoor installations, the meters and associated accessories shall be protected by appropriate enclosure of level of protection IP 55 and ensuring compliance with above conditions.

In large multi-storeyed buildings, installation of a large number of energy meters at the ground floor (or first basement) switch-room for the convenience of the meter-reader poses high fire hazard. More than 24 energy meters on one switchboard is undesirable. In such cases, where number of energy meters to be installed for feeding exceeds 24, energy meters shall be installed at each floor and therefore, the rising main (bus trunking) with tapping point at individual floor shall be provided for meters.

The energy meters shall be protected by suitable circuit breaker. The provisions of 5.3.6.7 shall apply in case of energy meters installed in boards.

5.4.1.4.2 Main sources of energy, as given below shall be metered, as required at entry into the premises/ control panel:

a) utility grid points (high voltage/low voltage);

b) captive generator sets; and

c) on-site renewable energy system (if installed/operational) including net metering for grid connected system.

5.4.1.4.3 Testing, evaluation, installation and maintenance of energy meters shall be in accordance with the good practice [D-2(30)].

5.4.1.4.4 *Centralized metering system*

Smart metering and energy monitoring in a centralized metering system are used to monitor, measure and control the demand of electrical loads in a building. These systems are designed specifically for the control and monitoring of those facilities in a building which have significant electrical consumption, such as heating, ventilation, air conditioning, lifts, pumps and lighting installations at multiple locations in a campus. The scope may span from a single building to a group of buildings, such as residential apartments under common ownership, large multi-storeyed buildings, malls, university campuses, office buildings, retail store networks, factories, or any building with multi-tenanted occupancy. These systems provide metering, submetering and monitoring functions to allow facility and building managers to gather data and insight that allows them to make more informed decisions about demand management and demand control across their sites.

For such buildings with centralized metering, several main meters and sub-meters with following requirements should be provided:

a) Main meters should be digital energy meters with high accuracy, high sampling rates and power quality parameters, that is, harmonics, etc, for meters installed at incomer level;

b) Separate sub-meters should be provided for all energy end uses and functional areas that individually account for reasonable energy consumption in the building. These may include, but are not limited to, sub-meters for HVAC system; common area lighting, raw power, UPS, other common utility; lifts and escalators, pumps, external and internal lighting, individual units/flats/shops/offices; etc;

c) The sub-meters should be able to communicate data for monitoring. At a minimum, the sub-metering infrastructure should facilitate the aggregation of total energy use. For individual residential or commercial meters, if required it shall be controlled by the local electrical authority to take data for grid metering and later data be shared for emergency metering; and

d) Adequate smart metering and energy monitoring infrastructure should be installed in order to help monitor operational energy use and costs and to enable continuous energy performance improvement.

5.4.1.4.5 The *Central Electricity Authority* (*Installation and Operation of Meters*) *Regulations*, 2006, as amended from time-to-time shall also be complied with.

5.4.2 *Main Switches and Switchboard*

5.4.2.1 All main switches shall be either of metal-clad enclosed pattern or of any insulated enclosed pattern which shall be fixed at close proximity to the point of entry of supply. Every switch shall have suitable ingress protection level rating (IP), so that its operation is satisfactory and safe in the environment of the installation. All works under 5.4 shall comply with the provisions of relevant Indian Standards and good practice [D-2(1)].

NOTE — Woodwork shall not be used for the construction or mounting of switches and switch boards installed in a building.

5.4.2.2 *Location*

The main switchboard shall comply with the following requirements relating to its location:

a) The location of the main board should be such that it is easily accessible to fireman and other personnel to quickly disconnect the supply in case of emergencies. If the room is locked for security reasons, means of emergency access, by schemes such as break glass cupboard, shall be incorporated;

b) Main switch board shall be installed in rooms or fire safe cupboards so as to safeguard against operation by unauthorized personnel. Otherwise, the main switch board shall have lock and key facility for small installations in residences or other occupancies having sanctioned loads less than 5 kW;

c) Switchboards shall be placed only in dry situations and in ventilated rooms and they shall not be placed in the vicinity of storage batteries or exposed to chemical fumes;

d) In damp situation or where inflammable or explosive dust, gas or vapour is likely to be present, the switchboard shall be totally enclosed and shall have adequate degree of ingress protection (IP). In some cases, flameproof enclosure may be necessitated by particular circumstances {*see* accepted standard [D-2(31)]};

e) Switchboards shall not be erected above gas stoves or sinks, or within 2.5 m of any washing unit in the washing rooms or laundries, or in bathrooms, lavatories or toilets, or kitchens;

f) In case of switchboards unavoidably fixed in places likely to be located outdoor, exposed to weather, drip, or to abnormal moist temperature, the outer casing shall be weatherproof and shall be provided with glands or bushings or adopted to receive screwed conduit, according to the manner in which the cables are run. The casing as well as cable entries shall have suitable IP ratings according to the installation;

g) Adequate illumination shall be provided for all working spaces around the switchboards; and

h) Easy access to the enclosure around switchgear is essential to enable easy and safe operation and maintenance. The provisions as given in **5.3.6.7** including requirements for sufficient clearances shall be complied with.

5.4.2.3 Metal-clad switchgear shall be mounted on any of the following types of boards:

a) *Fixed-type metal boards* — These shall consist of an angle or channel iron frame fixed on the wall or on floor and supported on the wall at the top, if necessary;

   NOTE — Such type of boards is suitable for both small and large switchboards. They are particularly suitable for large switchboards for mounting number of switchgears or high capacity metal-clad switchgear or both in an arrangement which do not require rear access.

b) *Protected-type switchboards* — A protected switchboard is one where all of the switchgear and conductors are protected by metal or halogen free plastic enclosures. They may consist of a metal/plastic cubicle panel, or an iron frame upon which metal-clad switchgears are mounted. They usually consist of a main switch, busbars and circuit breakers or fuses controlling outgoing circuits; and

c) *Outdoor-type switchboards* — An outdoor-type switchboard is one which is totally enclosed and UV ray protected and having high ingress protection against dust and moisture and vermin-proof and high impact resistant (IP 55 or higher and IK 10). Such switchboards are of cubicle type and also provide high impact resistance. Cubicle type boards shall be with hinged doors interlocked with switch-operating mechanisms. The doors of these switchboards shall have facility to ensure that it is always in closed conditions. All such switches shall bear labels indicating their functions.

   NOTE — Such switchboards shall be located away from areas likely to be crowded by the public.

Open type switchboards, wherever existing in old buildings, shall be phased out and replaced with protected-type switchboards with suitable circuit breakers. Switchboards should be composite including incoming and outgoing circuit breakers, meters, cable alleys, bus-bars, accessories, etc.

5.4.2.4 *Recessing of boards*

Where so specified, the switchboards shall be recessed in the wall. Ample room shall be provided at the back for connection and at the front between the switchgear mountings.

5.4.2.5 *Marking of apparatus* {*see also* accepted standards [D-2(32)]}

Where a board is connected to voltage higher than 250 V, all the apparatus mounted on it shall be marked with the following colours to indicate the different poles or phases to which the apparatus or its different terminals may have been connected:

a) *Alternating current* (*three-phase*) *system*:

   Phase 1 – red, Phase 2 – yellow and Phase 3 – blue; and
   1 Neutral – black

b) *Direct current* (*three-wire system*):

   2 outer wire, Positive – red and Negative – blue; and
   1 Mid wire (Neutral) – black

Where four-wire three-phase wiring is done, the neutral shall be in one colour and the other three phase conductors in another colour (preferably red) or shall be suitably tagged or sleeved to ensure fool proof identification.

NOTE — Generally red colour identification is adopted for the phase conductors and black for neutral with additional tags or sleeves or coloured tapes at terminations.

Earth continuity conductor shall be marked with green colour or green with yellow line.

Where a board has more than one switchgear, each such switchgear shall be marked to indicate the section of the installation it controls. The main switchgear shall be marked as such. Where there is more than one main switchboard in the building, each such switchboard shall be marked to indicate the section of the installation and/or building it controls.

All markings shall be clear and permanent.

5.4.2.6 *Drawings*

Before proceeding with the actual construction, a proper drawing showing the detailed dimensions and design including the disposition of the mountings of the boards, which shall be symmetrically and neatly arranged for arriving at the overall dimensions, shall be prepared along the building drawing. Such drawings will show the mandatory clearance spaces if any, and clear height below the soffit of the beam required to satisfy regulations and safety considerations, so that other designers or installers do not get into such areas or spaces for their equipment.

5.4.3 *Distribution Boards*

A distribution board comprises of one or more protective devices against overcurrent and ensuring the distribution of electrical energy to the various circuits. Distribution board shall provide plenty of wiring space, to allow working as well as to allow keeping the extra length of connecting cables, likely to be required for maintenance.

5.4.3.1 Main distribution board shall be provided with a circuit breaker on each pole of each circuit, on the phase or live conductor and a link on the neutral or earthed conductor of each circuit. The switches shall always be linked.

All incomers should be provided with surge protection devices depending upon the current carrying capacity and fault level (*see* **11**). Surge protecting devices should be provided with backup circuit breaker/fuses, wherever required.

5.4.4 *Branch Distribution Boards*

5.4.4.1 Branch MCB distribution boards shall be provided, along with earth leakage protective device (RCCB/RCD) in the incoming, with a miniature circuit breaker of adequate rating/setting chosen on the live conductor of each sub-circuit and the neutral conductor shall be connected to a common link and be capable of being disconnected individually for testing purposes. At least one spare circuit of the same capacity shall be provided on each branch distribution board. Further, the individual branching circuits (outgoing) shall be protected against over-current with miniature circuit breaker of adequate rating. In residential/industrial lighting installations, the various circuits shall be separated and each circuit shall be individually protected so that in the event of fault, only the particular circuit gets disconnected. In order to provide protection against electric shock due to leakage current for human being, a 30 mA RCCB/RCD shall be installed at distribution board incomer of buildings, such as residential, schools and hospitals. For all other buildings, a 100 mA RCCB/RCD will suffice for protection against leakage current.

In case of phase segregated distribution boards, earth leakage protective device shall be provided in the sub-incomer to provide phase-wise earth fault protection. The provision of sub-incomer in distribution board shall be as per consumer requirement.

5.4.4.2 Common circuit shall be provided for installations at higher level (those in the ceiling and at higher levels, above 1 m, on the walls) and for installations at lower level but with separate switch control (sockets for portable or stationery plug in equipment). For devices consuming high power and which are to be supplied through supply cord and plug, separate wiring shall be done. For plug-in equipment provisions shall be made for providing RCCB/RCD protection in the distribution board. They shall be selected as per the type of load. The details of RCD classes are available in Part 1 'General and common aspects, Section 10 Protection for safety — Protection against electric shock' of good practice [D-2(1)].

5.4.4.3 It is preferable to have additional circuit for kitchen and bathrooms. Such sub-circuit shall not have more than a total of ten points of light, fans and 6 A socket-outlets. The load of such circuit shall be restricted to 800 W and the wiring with minimum 1.5 mm^2 copper conductor cable is recommended. If a dedicated circuit is planned for light fixtures, the load of such circuit shall be restricted to 800 W or 20 points whichever is less and the wiring with 1.5 mm^2 copper conductor cable is recommended. If a dedicated circuit is planned for 6 A sockets the load of such circuit shall be restricted to 800 W or a maximum of 8 numbers whichever is less, controlling MCB should be sized accordingly. The wiring shall be with 1.5 mm^2 copper conductor cable. If a separate fan circuit is provided, the number of fans in the circuit shall not exceed ten. Power sub-circuit shall be designed according to the load but in no case shall there be more than two 16A outlets on each sub-circuit which can be wired with 4 mm^2 copper conductor cable for miscellaneous socket loads and shall be with 4 mm^2 copper conductor cable for equipment consuming more than 1 kW. Power sockets complying with the accepted standards [D-2(33)] with current rated according to their starting load, wiring, MCB, etc, shall be designed for special equipment space heaters, air conditioners, heat pumps, VRF, etc.

For feeding final single phase domestic type of loads or general office loads it is advisable to introduce additional cables if required to allow lowering of short circuit rating of the switchgear required at user end so that use of hand held equipment, etc fed through flexible cords is safe.

5.4.4.4 The circuits for lighting of common area shall be separate. For large halls 3-wire control with individual control and master control installed near the entrance shall be provided for effective conservation of energy. Occupancy sensors, movement sensors, lux level sensors, etc, may also be considered as switching options for lights, fans, TV, etc, for different closed spaces [*see* also relevant guidelines/best practices (Handbook on 'Sustainability in Buildings')].

5.4.4.5 Where daylight is abundantly available, particularly in large halls, lighting in the area near the windows likely to receive daylight shall have separate controls for lights, so that they can be switched off/automatically reduce intensity selectively when daylight is adequate, while keeping the lights in the areas remote from the windows on [*see* also relevant guidelines/best practices (Handbook on 'Sustainability in Buildings')].

5.4.4.6 Circuits for socket-outlets may be kept separate from circuits feeding fans and lights. Normally, fans and lights may be wired on a common circuit. In large spaces, circuits for fans and lights may also be segregated. Lights may have group control in large halls and industrial areas. While providing group control, consideration may be given for the nature of use of the area lit by a group. Consideration has to be given for the daylight utilization, while grouping, so that a group feeding area near windows receiving daylight can be selectively switched off during daylight period.

5.4.4.7 The load on any low voltage sub-circuit shall not exceed 3 000 W. In case of a new installation, all circuits and sub-circuits shall be designed with an initial load of about 2 500 W, so as to allow a provision of 20 percent increase in load due to any future modification. Power sub-circuits shall be designed according to the load, where the circuit is meant for a specific equipment. Good practice is to limit a circuit to a maximum of three sockets, where it is expected that there will be diversity due to use of very few sockets in large spaces (example sockets for use of vacuum cleaner). General practice is to limit it to two sockets in a circuit, in both residential and non-residential buildings and to provide a single socket on a circuit for a known heavy load appliance such as air conditioner, cooking range, etc.

5.4.4.8 In wiring installations at special places like construction sites, stadia, shipyards, open yards in industrial plants, etc, where a large number of high wattage lamps may be required, there shall be no restriction of load on any circuit but conductors used in such circuits shall be of adequate size for the load and proper circuit protection shall be provided. The distribution boards (DBs) used in these areas shall be of UV resistant, double insulated type with IP 66 or higher degree of protection. Power tools and other temporary equipment connected to these DBs shall be sufficiently protected against electrical faults. Insulated IP 66 sockets complying with the accepted standards [D-2(28)] used in these DBs shall have interlocking facility in addition to protection to ensure safe plugging and unplugging of these equipment.

5.4.5 *Location of Distribution Boards*

a) The distribution boards shall be located as near as possible to the centre of the load they are intended to control;

b) These shall be fixed on suitable stanchion or wall and shall be accessible for replacement/reset of protective devices and shall not be more than 1.8 m from floor level;

c) These shall be of either metal-clad type, or polycarbonate enclosure of minimum IP 42. But, if exposed to weather or damp situations, these shall be of the weatherproof type conforming to IP 55 and, if installed where exposed to explosive dust, vapour or gas, these shall be of flameproof type in accordance with accepted standards [D-2(34)]. In corrosive atmospheres, these shall be treated with anti-corrosive preservative or covered with suitable plastic compound;

d) Where two and/or more distribution boards feeding low voltage circuits are fed from a supply of low voltage, the metal case shall be marked 'Danger 415 Volts' and identified with proper phase marking and danger marks;

e) Each shall be provided with a circuit list giving diagram of each circuit which it controls and the current rating of the circuit and capacity of MCB;

f) In wiring branch distribution board, total load of connecting devices shall be divided as far as possible evenly between the number of ways in the board leaving spare circuits for future extension;

g) Distribution board shall not be located at structural expansion joints of the building;

h) Distribution board/other electrical outlets shall have a minimum calculated separation distance from lightning protection down-conductors to avoid flash over in case of lightning; and

j) Walls with flushed distribution boards shall have adequate support behind and surrounding so that there is no physical weight of the distribution board on the civil structure around. Electrical switch sockets, etc shall also be avoided to be mounted behind the distribution board to avoid touching the board from behind.

5.4.6 *Protection of Circuits*

a) Appropriate protection shall be provided at switchboards, distribution boards and at all levels of panels for all circuits and sub-circuits against short circuit, over-current and other parameters as required. The protective device shall be capable of interrupting maximum short circuit current and the prospective earth fault current that may occur, without danger. The ratings and settings of the protective devices such as MCB shall be coordinated so as to afford selectivity in operation and in accordance with accepted standards [D-2(35)];

b) Where circuit-breakers are used for protection of a main circuit and of the sub-circuits derived therefrom, discrimination in operation may be achieved by adjusting the protective devices of the sub-main circuit-breakers to operate at lower current settings and shorter time-lag than the main circuit-breaker;

c) Where HRC type fuses are used for back-up protection of circuit-breakers, or where HRC fuses are used for protection of main circuits and circuit-breakers for the protection of sub-circuits derived there from, in the event of short-circuits protection exceeding the capacity of the circuit-breakers, the HRC fuses shall operate earlier than the circuit-breakers; but for smaller overloads within the short-circuit capacity of the circuit-breakers, the circuit-breakers shall operate earlier than the HRC fuse blows;

d) The current rating of a circuit breaker shall not exceed the current rating of the smallest cable in the circuit protected by it; and

e) All distribution board or panel incomer may be protected by a surge protection device, if found necessary (*see* **11**). Separate CB with proper enclosure may be required in series with the surge protection device with main incomer. Back-up CB shall be of the capacity not lower than that recommended by the SPD manufacturer. Short circuit withstand capability of the SPDs should be coordinated with the CB and SPD should be selected to be matching the fault power expected/calculated at that point.

5.4.7 *Cascading, Discrimination and Limitation*

Cascading and discrimination in switchgear downstream and upstream shall be designed and maintained such that the continuity of power in case of any abnormal conditions such as overload, short circuit and earth faults, etc is maintained and only faulty circuit is isolated and power is made available to other loads.

Cascading technique allows the designer to select circuit breakers of lower breaking capacities. Utilizing the current limiting effect of the incoming breaker, outgoing breaker can sustain the higher faults than its capacity and even maintain the discrimination. The provisions of good practice [D-2(1)] and relevant Indian Standards shall be complied with while carrying out necessary works under **5.4**.

5.5 Protection Class of Equipment and Accessories

The class of ingress protection (IP) and protection against mechanical impact (IK) {*see also* accepted standard [D-2(36)]} shall be specific depending on the requirement at the place of installation.

5.6 Voltage and Frequency of Supply

It should be ensured that all equipment connected to the system including any appliances to be used on it are suitable for the voltage and frequency of supply of the system. The nominal values of low systems in India are 240 V single phase and 415 V a. c. three phase, respectively, and the frequency is 50 Hz.

NOTE — The design of the wiring system and the sizes of the cables should be decided taking into account following factors:

a) *Voltage drop* — This should be kept below 6 percent to ensure proper functioning of all electrical appliances and equipment including motors.

b) Thermal limit based current carrying capacity of the cable with appropriate derating factors applicable to the installation conditions.

c) Capacity to withstand the let through fault current based on the fault level and the controlling switchgear disconnection characteristics.

5.7 Rating of Cables and Equipment

The rating of the cables and the equipment shall be chosen based on the relevant Indian Standards, good practice [D-2(1)] and accepted standard [D-2(37)] read with availability of the material in the market.

5.8 Installation Circuits

5.8.1 The nominal cross-sectional area of copper phase conductors in a. c. circuits and of live conductors in d. c.

circuits shall be not less than the values specified below:

Sl No. (1)	*Type of Circuit* (2)	*Minimum Copper Wire Size* (3)	*Remarks* (4)
i)	Lighting	1.5 mm^2	Per circuit for 2 or more circuits
ii)	Socket-outlets, 6 A	2.5 mm^2	Earthing of the 3rd pin shall be ensured
iii)	Socket-outlets, 16 A	2.5 mm^2	1
iv)	Water heater < 3 kW	2.5 mm^2	1
v)	Heaters or electric equipment more than or equal to 3 kW	4.0 mm^2	1
vi)	Free standing electric range Separate oven and/or cook top	4.0 mm^2	1
vii)	Air conditioner up to 2 T	4.0 mm^2	1
viii)	Permanently connected appliances including dishwashers, heaters, etc	2.5 mm^2	1 above 10 A. Up to 10 A can be wired as part of a socket-outlet circuit
ix)	Appliance rated > 3 kW < 6 kW	6.0 mm^2	–
x)	Submains to garage or out-building	2.5 mm^2	1 for each
xi)	Mains cable		It should be based on demand load/peaking loads and future loading

NOTE — The minimum conductor size in point wiring shall not be less than 1.5 mm^2 copper conductor cable for fixed (permanent) wiring insulations.

5.8.2 For conductor sizes less than or equal to 25 mm^2, only copper conductor cables shall be used since aluminium conductor cables in sizes less than 25 mm^2 may cause termination problems leading to heating at the terminals and enhance the possibility of a fire.

In case of very important public buildings and multi-storey buildings, for connections to meter board and connections from tap-off box to floor panel and beyond, use of copper conductor cable up to 50 mm^2 be considered to avoid frequent failure and fire accidents.

5.8.3 Switch or isolator controlling a water heater or geyser should not be located within 1 m from the location of a shower or bath tub, to avoid a person in wet condition reaching the switch or isolator. It is preferable to provide the control switch outside the bath room near the entrance and provide an indication at the water heater. A socket or a connector block with suitable protection against water spray should be provided to connect the water heater. The above considerations apply to switches for outdoor lights and other appliances, with the object of avoidance of operation of a switch when a person is wet.

5.8.4 Sockets in kitchen, bathroom, toilet, garage, etc, should not be provided within a height of 1 m from the ground level. Similar care has to be taken for installations involving fountains, swimming pools, etc. Light fittings in such areas should be fed at low voltage, preferably through an isolating transformer with a proper earth leakage protection. Where possibility of a person in contact with a wet surface has to operate or touch an electrical switch or an appliance the circuit should be protected by a 30 mA RCCB/RCD, as applicable.

5.8.5 *Selecting and Installing Cables*

5.8.5.1 *Cable types*

For the purpose of this NBCS, cables above 1 mm^2 shall have stranded conductors. All cables when installed, shall be adequately protected against mechanical damage. This can be carried out by either having additional protection, such as being enclosed in PVC conduit or metal pipes, or placing the cables in a suitable location that requires no additional protection. The cables for wiring circuits in electrical installation shall have the appropriate wire size matching the requirement of the loads. The following table gives the recommendations for different types of loads:

For the mains cable	Cross-linked polyethylene (XLPE) cable
For internal wiring	Class II copper conductor flame retardant, low smoke halogen (FRLSH) cable
Fire alarm and other related services	Halogen free flame retardant (HFFR)/Fire survival copper conductor cable
For main earth or main equipotential wire	Poly vinyl chloride (PVC) insulated copper wire
Underground installation and installation in cable trench, feeders between buildings, etc	PVC insulated, PVC sheathed armoured cables or XLPE insulated, PVC sheathed cables armoured cables
Installation in plant rooms, switch rooms, etc, on cable tray or ladder or protected trench, where risk of mechanical damage to cable does not exist	PVC insulated, PVC sheathed or XLPE insulated, PVC sheathed unarmoured cables

5.8.5.2 *Circuit wire sizes*

Recommended minimum wire sizes for various circuits is given below:

Sl No. (1)	*Circuits* (2)	*Minimum Size of Copper Conductor Cable* (3)	*Wire Colour* (4)
i)	1-way lighting	2 + E cable of 1.5 mm^2	Red-black and green-yellow
ii)	2-way lighting control	3 wire cable of 1.5 mm^2	Red-white-blue
iii)	Storage water heaters up to 3 kW	2 + E cable of 2.5 mm^2 (stranded conductors)	Red-black and green-yellow
iv)	Storage water heaters between 3 kW and 6 kW	2 + E cable of 4 mm^2 (stranded conductors)	Red-black and green-yellow
v)	Socket-outlets and permanent connection units	2 + E cable of 2.5 mm^2 (stranded conductors)	Red-black and green-yellow

Table (*Concluded*)

Sl No. (1)	*Circuits* (2)	*Minimum Size of Copper Conductor Cable* (3)	*Wire Colour* (4)
vi)	Submains to garages or out buildings	2 + E cable 2.5 mm^2 (stranded conductors)	Red-black and green-yellow
vii)	Cooking hobs	2 + E cable 1.5 mm^2	Red-black and green-yellow
viii)	Separate ovens	2 + E cable 4 mm^2 (stranded conductors)	Red-black and green-yellow
ix)	Electric range	2 + E cable 6 mm^2 (stranded conductors)	Red-black and green-yellow
x)	Mains	2 wire cable Upto 25 mm^2 (stranded conductors)	Red-black
xi)	Main equipotential bonding wire	4 mm^2 (stranded conductors)	Green-yellow
xii)	Main earth wire	6 mm^2 (stranded conductors)	Green-yellow

NOTES

1 2 + E cable is also known as twin and earth wire cable (two wires and earth).

2 Earth wire can be as per the following:

- a) Green-Yellow throughout their length with, in addition, light blue markings at the terminations; or
- b) Light blue throughout their length with, in addition, green/yellow markings at the terminations.

3 The above sizes are recommendatory and shall be modified as per voltage drop, starting current, distance from DB, etc.

5.8.6 *Requirements for Physical Protection of Underground Cables*

Sl No. (1)	*Protective Element* (2)	*Specifications* (3)
i)	Bricks	a) 100 mm minimum width b) 25 mm thick c) sand cushioning 100 mm and sand cover 100 mm
ii)	Concrete slabs	At least 50 mm thick
iii)	Plastic slabs (polymeric cover strips) fibre reinforced plastic	At least 10 mm thick, depending on properties and has to be matched with the protective cushioning and cover
iv)	PVC conduit or PVC pipe or stoneware pipe or hume pipe	The pipe diameter should be such so that the cable is able to easily slip down the pipe
v)	Galvanized pipe	The pipe diameter should be such so that the cable is able to easily slip down the pipe

The trench shall be backfilled to cover the cable initially by 200 mm of sand fill; and then a plastic marker strip shall be put over the full length of cable in the trench. The marker signs shall be provided where any cable enters or leaves a building. This will identify that there is a cable located underground near the building. The trench shall then be completely filled. If the cables rise above ground to enter a building or other structure, a mechanical protection such as a GI pipe or PVC pipe for the cable from the trench depth to a height of 2.0 m above ground shall be provided.

5.9 Lighting and Levels of Illumination

5.9.1 *General*

Lighting installation shall take into consideration the numerous factors on which the quality and quantity of artificial lighting depends. Recent practice in illumination is to provide the required illumination with a large number of light sources (not of higher illumination level) instead of fewer number of light sources of higher illumination level, to produce higher uniformity in illumination level.

With the increase in energy costs and awareness of the need to conserve energy for the protection of the environment, there has been a drastic change in the use of light sources during the last 10 years. Fluorescent lamps [tubular lamp (TL) and compact fluorescent lamp (CFL)] are no longer available in the market. Use of general lighting service (GLS) lamps, known as light bulbs, has almost become extinct. The space vacated by these light sources has been taken over by LED lamps in different configurations in the form of LED based bulbs, tube lights, ceiling flush light sources and floodlights with different wattages.

With this the lighting design has become more complex. With the developments in the types of light sources and their control systems now available, lighting design goes with the concept of better light with less energy and least impact on environment.

Automatic lighting control schemes may be considered to have efficient utilization of lights. Automatic controls can take care of the switching off when the space served has no activity or is illuminated by daylight.

While carrying out lighting design and layout reference shall also be made to good practice [D-2(38)].

5.9.2 *Electrical Installations for Lighting*

The concepts or needs of energy conservation today require more lights to be provided so that different sets of lights are used to light up the area of activity to the required higher level of lighting needed for the activity and provide a general minimum background level of lighting. Any space requires two or three different combination of lighting sets associated with the activity and this may require the wiring to be provided to accommodate the lighting groups in different circuits with group controls, automatic controls and remote controls.

Availability of LED lights with a wide range from 1 W to 100 W allows designers to provide spot task lighting of a high illumination level combined with a general space lighting of low illumination. As light follows the inverse square law, provision of the light source close to the task reduces the energy need.

Lighting demand for buildings should be considered as per type of building. Where nothing is specified, for lighting demand of any type of building a maximum of 13 W/m^2 of all built-up areas including balconies. Covered parking areas may be considered at 3.23 W/m^2 including balconies is to be considered. Service areas, corridors, etc, may be considered with very basic diversity of 80 percent to 100 percent. Power requirements shall be considered at least 55 W/m^2 with an overall diversity not exceeding 50 percent. These shall be excluding defined loads such as lifts, plumbing system, firefighting systems, ventilation requirement, etc.

Light emitting diode (LED) lamps have non-linear characteristics and require specifically made controlgear for each type of lamp for their proper operation. In some cases the controlgear is integral with the lamp, in some with light fitting and in some it is external. The electrical installation and wiring has to take this into account and provide appropriate space for such controlgear. There will be heat emission, introduction of harmonics, etc, and they also consume some energy. The electrical and lighting system design has to keep this aspect in the wiring design and installation.

5.9.3 *Principles of Lighting*

When considering the function of artificial lighting, attention shall be given to the following principle characteristics before designing an installation:

a) Illumination and its uniformity.

b) Special distribution of light. This includes a reference to the composition of diffused and directional light, direction of incidence, the distribution of luminances and the degree of glare.

c) Colour of the light and colour rendition.

d) Natural light sources, if possible such as light tubes.

e) System wattage of the luminaire proposed.

5.9.4 The variety of purposes which have to be kept in mind while planning the lighting installation may be broadly grouped as:

a) industrial buildings and processes;

b) offices, schools and public buildings;

c) surgeries and hospitals; and

d) hostels, restaurants, shops and residential buildings.

5.9.4.1 It is important that appropriate levels of illumination for these and the types and positions of fittings determined to suit the task and the disposition of the working planes are ensured.

5.9.5 For detailed requirements for lighting and lighting design and installations, reference shall be made to the good practice [D-2(38)] and provisions in Part D 'Building Services, Section 1 Lighting and Natural Ventilation' of this NBCS.

5.10 In locations where the system voltage exceeds 415 V three phase, as in the case of industrial locations, for details of design and construction of wiring installation, reference may be made to good practice [D-2(18)].

5.11 Guideline for Electrical Layout in Residential Buildings

For guidelines for electrical installation in residential buildings, reference may be made to accepted standard [D-2(39)] and good practice [D-2(1)].

A typical distribution scheme in a residential building with separate circuits for lights and fans and for power appliances is given in Fig. 3.

5.12 For detailed information regarding the installation of different electrical equipment, reference may be made to good practice [D-2(40)].

FIG. 3 WIRING DIAGRAM FOR A TYPICAL DISTRIBUTION SCHEME IN A RESIDENTIAL BUILDING FLAT

6 WIRING

6.1 General

The generic guidelines for wiring in buildings depending on the type of occupancy, local conditions, material selection and other relevant points are covered hereunder. Also, the construction requirements, safety aspects to be considered during construction and maintenance aspects which should be considered during construction are addressed. All works under this shall also comply with the relevant Indian Standards and provisions in good practice [D-2(1)].

6.1.1 *Estimation of Load Requirements*

All conductors, switches and accessories shall be of such size as to be capable of carrying, without their respective ratings being exceeded, the maximum current which will normally flow through them.

In estimating the current to be carried by any conductor the following ratings shall be taken, unless the actual values are known or specified for these elements:

Sl No. (1)	*Element* (2)	*Rating*, W (3)
i)	Light point	60
ii)	Fan point	75
iii)	6 A 3/5 pins socket-outlet	100
iv)	16 A 3/6 pins socket-outlet	2 000
v)	High pressure mercury vapour (HPMV) lamps, high pressure sodium vapour (HPSV) lamps	According to their capacity, controlgear losses shall be also considered as applicable
vi)	Geyser (storage type)	2 000
vii)	Geyser (instant)	3 000
viii)	Computer point	150
ix)	Printer, laser	1 500
x)	Air conditioner:	
	a) Up to 1.5 TR	2 000
	b) 1.5 to 2 TR	3 000

6.1.2 *Commencement of Electrical Work*

Electrical installation in a new building shall normally begin with conduit laying at the commencement of preparations for first roof concreting work. The necessary conduits and ducts shall be positioned firmly by tying the conduit to the reinforcement before concreting in an RCC building. Location of fan points should be properly marked and fan clamp boxes should be provided along with conduit laying in roof. Care should be taken to avoid use of damaged conduit or ducts, the conduits ends shall be given suitable anti-corrosive treatment and holes blocked off by putties or caps to protect conduits from getting blocked. All conduit openings and junction box openings, etc shall be properly protected against entry of mortar, concrete, etc during construction. Laying of conduits in walls shall start with the taking up of wall construction work. In case of surface wiring, the work will start after completion of interior plaster including curing. The wiring, fixing of switch boxes and fixing of switches will start only after ensuring necessary weatherproof area with locking arrangement is available to take up electrical work.

6.2 Selection of Size of Conductors

The size of conductors for circuits shall be selected after fixing the location of main sub-station, main switchboard for the building, location of distribution board and the electrical points under the planning of electrical services. The overall voltage drop from the transformer end to consumer's final distribution board shall not exceed six percent. The voltage drop of six percent will be divided between different points indicated above in such a way that from the distribution board to the last point shall be three percent. From main board to distribution board, from distribution board to sub distribution board if any, circuit wiring from DB/SDB to switch board and from switch board to light/fan points/plug points shall be with Class II category copper conductors. The size of the conductor cable shall be decided based on the maximum load on each point. In main/submain/circuit/sub-circuit, the circuit-breaker shall be selected to match the current rating of the circuit to ensure the desired protection.

6.3 Branch Switches

Where the supply is derived from a three-wire or four-wire source, and distribution is done on the two-wire system, all branch switches shall be placed in the outer or live conductor of the circuit and no single phase switch or protective device shall be inserted in the middle wire, earth or earthed neutral conductor of the circuit. Single-pole switches (other than for multiple control) carrying not more than 16 A may be of flush/modular type. For controlling points for air conditioners and geysers, suitable MCB type switches shall be provided.

6.4 Layout and Installation Drawing

6.4.1 The electrical layout should be drawn indicating properly the locations of all outlets, such as lamps, fans, appliances (both fixed and movable), and motors and best route for wiring.

6.4.2 All runs of wiring and the exact positions of all points of switch-boxes and other outlets shall be first marked on the plans of the building and approved by the engineer-in-charge or the owner before actual commencement of the work.

6.4.3 Industrial layout drawings should indicate the relative civil and mechanical details.

6.4.4 *Layout of Wiring*

The layout of wiring should be designed keeping in view disposition of the lighting system to meet the illumination levels. All wirings shall be done on the distribution system with main and branch distribution boards at convenient physical and electrical load centres. All types of wiring, whether concealed or unconcealed, should be as near the ceiling as possible. In all types of wirings due consideration shall be given for neatness and good appearance.

6.4.5 Balancing of circuits in three-wire or poly-phase installation shall be arranged beforehand. Proper balancing can be done only under actual load conditions. Conductors shall be so enclosed in earthed metal or incombustible insulating material that it is not possible to have ready access to them. Means of access shall be marked to indicate the voltage present.

Where terminals or other fixed live parts between which a voltage exceeding 250 V exists are housed in separate enclosures or items of apparatus which, although separated are within reach of each other, a notice shall be placed in such a position that anyone gaining access to live parts is warned of the magnitude of the voltage that exists between them.

Where loads are single phase, balancing should be for the peak load condition based on equipment usage. Facility for change should be built into the distribution design.

NOTE — The above requirements apply equally to three-phase circuits in which the voltage between lines or to earth exceeds 250 V and to groups of two or more single-phase circuits, between which medium voltage may be present, derived therefrom. They apply also to 3 wire d.c. or 3 wire single-phase a.c. circuits in which the voltage between lines or to earth exceeds 250 V and to groups of 2 wire circuits, between which medium voltage may be present, derived there from.

6.4.6 Low voltage wiring and associated apparatus shall comply, in all respects, with the requirements of Regulation 35, 36, 37, 39, 40, 41 and 42 of *Central Electricity Authority* (*Measures Relating to Safety and Electric Supply*) *Regulations*, 2023, as amended from time to time (*see* Annex B).

6.5 Conductors and Accessories

6.5.1 *Conductors*

Conductors for all the internal wiring shall be of copper. Conductors for power and lighting circuits shall be of adequate size to carry the designed circuit load without exceeding the permissible thermal limits for the insulation. For final selection of wiring to larger loads, the current carrying capacity will preside. The conductor size shall also be based on the voltage drop in the line so as to provide a terminal voltage not below the prescribed voltage requirement.

The conductor for final sub-circuit for fan and light wiring shall have a nominal cross-sectional area not less than 1.50 mm^2 copper. The cross-sectional area of conductor for power wiring shall be not less than 2.5 mm^2 copper. The minimum cross-sectional area of conductor of flexible cord shall be 1.50 mm^2 copper. All copper conductors used in wiring shall be of class II category for permanent wiring system.

In existing buildings where aluminum wiring has been used for internal electrification, changeover from aluminum conductor cables to copper conductor cables is recommended as it has been found that aluminum conductors pose a number of hazards.

NOTE — It is advisable to replace wiring which is more than 30 years old as the insulation also would have deteriorated, and will be in a state to cause failure on the slightest of mechanical or electrical disturbance.

6.5.2 *Flexible Cables and Flexible Cords*

Flexible cables and cords shall be of copper and stranded, and protected by flexible conduits or tough rubber or PVC sheath to prevent mechanical damage.

6.5.3 *Cable Ends*

When a stranded conductor having a nominal sectional area less than 6 mm^2 is not provided with cable sockets (thimbles/lugs) for end termination, all strands at the exposed ends of the cable shall be soldered together or crimped using suitable sleeve or ferrules.

6.5.4 *Special Risk*

Special forms of construction, such as flameproof enclosures, shall be adopted where there is risk of fire or explosion.

6.5.5 *Connection to Ancillary Buildings*

Unless otherwise specified, electric connections to ancillary buildings, such as out-houses, garages, etc adjacent to the main building and when no roadway intervenes shall be taken in an earthed GI pipe or heavy duty PVC or HDPE pipe of suitable size. This pipe can be taken either underground or over ground, however, in latter case, its height from the ground shall not be less than 5.8 m. This applies to both runs of mains or sub-mains or final sub-circuit wiring between the buildings.

6.5.6 *Expansion Joints*

Distribution boards shall be so located that the conduits shall not normally be required to cross expansion joints in a building. Where such crossing is found to be unavoidable, special care shall be taken to ensure that the conduit runs and wiring are not in any way put to strain or damaged due to expansion of building structure. Anyone of the standard methods of connection at a structural expansion joint shall be followed:

a) Flexible conduit shall be inserted at place of expansion joint;

b) Oversized conduit overlapping the conduit; and

c) Expansion box.

Supports and flexible joints shall be of same requirement as the rising main/bus duct in so far as resistance to seismic forces is concerned. This is further important when rising mains and bus-ducts cross expansion joints.

6.5.7 *Extra Low Voltage* (*Types of Wires/Cables*)

Extra low voltage services utilize various categories of cables/wires, such as fibre optic cable, co-axial cable, etc. These shall be laid at least at a distance of 300 mm from any power wire or cable. The distance may be reduced only by using completely closed earthed metal trunking with metal separations for various kind of cable. Special care shall be taken to ensure that the conduit runs and wiring are laid properly for low voltage signal to flow through it.

The power cable and the signal or data cable may run together under floor and near the equipment. However, separation may be required from the insulation aspect, if the signal cable is running close to a conductor carrying power at low voltage. All types of signal cables are required to have insulation level for withstanding 2 kV impulse voltage even if they are meant for service at low voltage.

6.6 Passing Through Walls, Floors and Expansion Joints

6.6.1 Where wires/cables are required to pass through walls, care shall be taken to see that wires/cables pass freely through protective pipe or box and that the wires pass through in a straight line without any twist or cross in wires. In case of wires crossing expansion joints in a recessed conduit system there shall be two loop wire boxes on two sides of the expansion joint which shall be connected with concentric pipes of different diameter in such a way that one box will hold the bigger diameter conduit while the other box will hold the smaller diameter conduit pipe. This way, the two sides can move freely as per structure without having any effect either on the structure or on the wiring system.

One of the following methods shall be employed for laying wires/cables:

a) *Conduit wiring system* (*see* **6.9**) — The conductor shall be drawn in either in a rigid steel conduit or a rigid non-metallic conduit conforming to relevant Indian Standards {*see* accepted standards [D-2(41)] and [D-2(42)]}. All conduits used for fire alarm and other fire related emergency relief services as well as security and UPS system shall only be of metallic conduit system.

The conduits shall be colour coded as per the purpose of wire carried in the same. The recommended colour coding may be in form of bands of colour (100 mm thick, with centre to centre distance of 300 mm) or coloured throughout. The colour scheme may be as follows:

Sl No. (1)	*Conduit Type* (2)	*Colour Scheme* (3)
i)	Power conduit	Black
ii)	Security conduit	Blue
iii)	Fire alarm conduit	Red
iv)	Extra low voltage conduit	Brown
v)	UPS conduit	Green

Conduit wiring system shall comply with relevant Indian Standards. The number of insulated conductors that can be drawn into rigid conduit is given in Table 1 (*see* Table 1A for rigid steel conduits and Table 1B for rigid non-metallic conduits). As far as possible, cables of one circuit shall be housed in one conduit only.

b) *Cable trunking/cable ways/race ways* (*see* **6.10**) — Cable trunking/cable ways/race ways system should be used when number of wires/small cable sizes to be laid is more than the conduit capacity. Care should be taken to have space in the trunking system to minimize heating of wires and to provide identification of the different circuits. These can be laid in both floor and ceiling. Adequate junction boxes, access points shall be provided to pull in and out wire.

Cable trunking or ducting system shall comply with accepted standards [D-2(43)].

c) *Tray and ladder rack* — As tray provides continuous support, unless mounted on edge or in vertical runs (when adequate strapping or clipping is essential), the mechanical strength of supported cable is not as important as with ladder-racking or structural support methods. Consequently, tray is eminently suitable for the smaller unarmoured cabling while ladder racks call for armoured cables or larger unarmoured cables as they provide the necessary strength to avoid sagging between supports. Both tray and ladder racks are provided with accessories to facilitate changes of route, and they provide no difficulty in this respect on vertical runs.

Cable tray/ladder racks and support systems shall be installed in such a way that the deflection between the spans shall be less than 1 percent of the span.

Power cables running in cable ladders both horizontal and vertical shall be fixed with proper clamps which can withstand the mechanical force created on the cable in case of short circuit current. The complete installation consisting of cables, ladders, clamps, ladder supports and fixtures shall also withstand the mechanical force of short circuit current. Only one layer of power cable shall be laid in a ladder. The minimum space between two cables shall be equal to the diameter of the biggest cable.

Cable tray and ladder system shall comply with accepted standard [D-2(44)].

6.6.2 Insulated conductors while passing through floors shall be protected from mechanical injury by means of rigid steel/non-metal conduit or by mechanical protection up to a height not less than 1.5 m above the floor and flush with the ceiling below. These steel conduits shall be earthed and securely bushed.

Power outlets and wiring in the floor shall be generally avoided. If not avoidable, false floor trunking or metal floor trunking should be used. Power sockets of adequate IP/IK rating shall be used.

False floor shall be provided where density of equipment and interconnection between different pieces of equipment is high. Examples are, mainframe computer station, telecommunication switch rooms, etc. Floor trunking shall be used in large halls, convention centres, open plan offices, laboratory, etc.

In case of floor trunking, drain points/weep holes shall be provided within the trunking for installation for convention centres, exhibition areas or any other place where water may spill into the trunking, as there might be possibility of water seepage in the case of wiring passing through the floors. Proper care should be taken for providing suitable means of draining of water. Possibility of water entry exists from floor washing, condensation in some particular weather and indoor temperature conditions. At the design stage, these aspects shall be assessed and an appropriate means of avoiding or reducing ingress of water and draining method shall be built in. Floor trunking outlets shall be suitably IP rated for protection against dust and water. Floor trunking shall be of adequate IK rating. Floor or ceiling trunking shall have a maximum of 40 percent fill.

Floor outlet boxes are generally provided for the use of appliances, which require a signal or communication connection. The floor box and trunking system should cater to serve both power distribution and the signal distribution, with appropriate safety and non-interference.

6.6.3 Where a wall tube passes outside a building and be exposed to weather, the outer end shall be bell-mouthed and turned downwards and properly bushed at the open end.

6.7 Wiring of Distribution Boards

6.7.1 All connections between parts of apparatus or between apparatus and terminals on a board shall be neatly arranged in a definite sequence, following the arrangements of the apparatus mounted thereon, avoiding unnecessary crossings.

6.7.2 Cables shall be connected to a terminal only by soldered or welded or crimped lugs using suitable sleeve, lugs or ferrules unless the terminal is of such a form that it is possible to securely clamp them without the cutting away of cables strands. Cables in each circuit shall be bunched together.

6.7.3 All bare conductors shall be rigidly fixed in such a manner that a clearance of at least 25 mm is maintained between conductors or opposite polarity or phase and between the conductors and any material other than insulation material.

6.7.4 If required, a pilot lamp shall be fixed and connected through an independent single pole switch and fuse to the busbars of the board. Leads connecting bus-bars to any instrument or indicating lamp or an outgoing connection switch or breaker face the same fault current that is applicable to the busbar and as such should be provided with a fuse capable of handling the prospective fault current.

6.7.5 In a hinged type board, the incoming and outgoing cables shall be fixed at one or more points according to the number of cables on the back of the board leaving suitable space in between cables and shall also, if possible, be fixed at the corresponding points on the switchboard panel. The cables between these points shall be of such length as to allow the switchboard panel to swing through an angle of not less than 90° and cables arranged and clamped in such a manner that the cables do not face bending, but only face a twist, when the hinged door is opened. The circuit breakers in such cases shall be accessible without opening the door of distribution board. Circuit breakers or any other equipment (having cable size more than 1.5 mm^2 multi-strand wire) shall also not be mounted on the door.

NOTE — Use of hinged type boards is discouraged, as these boards lead to deterioration of the cables in the hinged portion, leading to failures or even fire.

6.7.6 Wires terminating and originating from the protective devices shall be properly lugged and taped.

6.8 PVC-Sheathed Wiring System

6.8.1 *General*

Wiring with PVC-sheathed cables may be used for temporary installations for medium voltage installation and may be installed directly under exposed conditions of sun and rain or damp places.

6.8.2 *PVC Clamps/PVC Channel*

The clamps shall be used for temporary installations of 1 to 3 sheathed wires only. The clamps shall be fixed on wall at intervals of 100 mm in the case of horizontal runs and 150 mm in the case of vertical runs.

PVC channel shall be used for temporary installations in case of more than 3 wires or unsheathed wires. The channel shall be clamped on wall at intervals not exceeding 300 mm. PVC clamps/PVC channel shall conform to accepted standards.

6.8.3 *Protection of PVC-Sheathed Wiring from Mechanical Damage*

a) In cases where there are chances of any damage to the wirings, such wirings shall be covered with sheet metal protective covering, the base of which is made flush with the plaster or brickwork, as the case may be, or the wiring shall be drawn through a conduit complying with all requirements of conduit wiring system (*see* **6.9**); and

b) Such protective coverings shall in all cases be fitted on all down-drops within 1.5 m from the floor.

6.8.4 *Bends in Wiring*

The wiring shall not in any circumstances be bent so as to form a right angle but shall be rounded off at the corners to a radius not less than six times the overall diameter of the cable.

6.8.5 *Passing Through Floors*

All cables taken through floors shall be enclosed in an insulated heavy gauge steel conduit extending 1.5 m above the floor and flush with the ceiling below, or by means of any other approved type of metallic covering. The ends of all conduits or pipes shall be neatly bushed with porcelain, wood or other approved material.

6.8.6 *Passing Through Walls*

The method to be adopted shall be according to good practice. There shall be one or more conduits of adequate size to carry the conductors [*see* **6.9.1**(a)]. The conduits shall be neatly arranged so that the cables enter them straight without bending.

6.8.7 *Stripping of Outer Covering*

While cutting and stripping of the outer covering of the cables, care shall be taken that the sharp edge of the cutting instrument does not touch the rubber or PVC-sheathed insulation of conductors. The protective outer covering of the cables shall be stripped off near connecting terminals, and this protective covering shall be maintained up to the close proximity of connecting terminals as far as practicable. Care shall be taken to avoid hammering on link clips with any metal instruments after the cables are laid. Where junction boxes are provided, they shall be made moisture-proof with an approved plastic compound.

6.8.8 *Painting*

If so required, the tough rubber-sheathed wiring shall, after erection, be painted with one coat of oil-less paint or distemper of suitable colour over a coat of oil-less primer, and the PVC-sheathed wiring shall be painted with a synthetic enamel paint of quick drying type.

6.9 Conduit Wiring System

Conduit wiring system shall comply with accepted standards [D-2(45)]. Requirements relating to conduit wiring system with rigid steel and non-metallic conduits shall be as per **6.9.1** to **6.9.3**.

6.9.1 *Surface Conduit Wiring System with Rigid Steel Conduits*

a) *Type and size of conduit* — All conduit pipes shall conform to accepted standards [D-2(46)], finished with galvanized or stove enamelled surface. All conduit accessories shall be of threaded type and under no circumstance pin grip type or clamp type accessories shall be used. No steel conduit less than 16 mm in diameter shall be used. The number of insulated conductors that can be drawn into rigid steel conduit is given in Table 1A.

b) *Bunching of cables* — Unless otherwise specified, insulated conductors of a.c. supply and d.c. supply shall be bunched in separate conduits. For lighting and small power outlet circuits phase segregation in separate conduits is recommended.

c) *Conduit joints* — Conduit pipes shall be joined by means of screwed couplers and screwed accessories only {*see* accepted standard [D-2(47)]}. In long distance straight runs of conduit, inspection type couplers at reasonable intervals shall be provided or running threads with couplers and jam-nuts (in the latter case the bare threaded portion shall be treated with anti-corrosive preservative) shall be provided. Threaded portion on conduit pipes in all cases shall be between 11 mm and 27 mm long sufficient to accommodate pipes to full threaded portion of couplers or accessories. Cut ends of conduit pipes shall have no sharp edges or any burrs left to avoid damage to the insulation of conductors while pulling them through such pipes.

d) *Protection against dampness* — In order to minimize condensation or sweating inside the tube, all outlets of conduit system shall be properly drained and ventilated, but in such a manner as to prevent the entry of insects as far as possible.

e) *Protection of conduit against rust* — The outer surface of the conduit pipes, including all bends, unions, tees in the conduit system shall be adequately protected against rust particularly when such system is exposed to weather. In all cases, no bare threaded portion of conduit pipe shall be allowed unless such bare threaded portion is treated with anti-corrosive preservative or covered with suitable plastic compound.

f) *Fixing of conduit* — Conduit pipes shall be fixed by heavy gauge saddles, secured to suitable wood plugs or other plugs with screws in an approved manner at an interval of not more than 1 m, but on either side of couplers or bends or similar fittings, saddles shall be fixed at a distance of 300 mm from the centre of such fittings. Conduit fittings shall be avoided as far as possible on conduit system exposed to weather; where necessary, solid type fittings shall be used.

g) *Bends in conduit* — All necessary bends in the system including diversion shall be done by bending pipes; or by inserting suitable solid or inspection type normal bends, elbows or similar fittings; or fixing cast iron, thermoplastic or thermosetting plastic material inspection boxes; whichever is more suitable. Radius of such bends in conduit pipes shall be not less than 75 mm. No length of conduit shall have more than the equivalent of four quarter bends from outlet to outlet, the bends at the outlets not being counted.

h) *Outlets* — All outlets for fittings, switches, etc, shall be boxes of suitable metal or any other approved outlet boxes for either surface mounting or flush mounting system.

j) *Conductors* — All conductors used in conduit wiring shall preferably be stranded. No single-core cable of nominal cross-sectional area greater than 130 mm^2 shall be enclosed along in a conduit and used for alternating current.

k) *Erection and earthing of conduit* — The conduit of each circuit or section shall be completed before conductors are drawn in. The entire system of conduit after erection shall be tested for continuity using a fish wire and permanently connected to earth conforming to the requirements. Gas or water pipes shall not be used as earth medium. If conduit pipes are liable to mechanical damage they shall be adequately protected.

m) Inspection type conduit fittings, such as inspection boxes, draw boxes, bends, elbows and tees shall be so installed that they can remain accessible for such purposes withdrawal of existing cables or of new cables.

Table 1A Maximum Permissible Number of Single-Core Copper Cables up to and Including 1 100 V that can be Drawn into Rigid Steel Conduits

[*Clauses* 6.6.1(a) *and* 6.9.1(a)]

Sl No.	**Size of Cable** Nominal Cross-Sectional Area mm^2	**Size of Conduit** mm

viii)	35	–	–	–	–	2	–	4	3	7	5	8	6

NOTES

1 The table shows the maximum capacity of conduits for the simultaneously drawing of cables. The columns headed S apply to runs of conduit which have distance not exceeding 4.25 m between draw-in boxes and which do not deflect from the straight by an angle of more than 15. The columns headed B apply to runs of conduit which deflect from the straight by an angle of more than 15.

2 In case an inspection type draw-in box has been provided and if the cable is first drawn through one straight conduit, then through the draw-in box and then through the second straight conduit, such systems may be considered as that of a straight conduit even if the conduit deflects through the straight by more than 15.

3 Conductor sizes for cables and wires above and including 2.5 mm^2 core size shall be multi-stranded.

6.9.2 *Recessed Conduit Wiring System with Rigid Steel Conduit*

Recessed conduit wiring system shall be laid in concrete in the roof slab and in walls, and shall comply with all the requirements for surface conduit wiring system specified in **6.9.1(a)** to **6.9.1(k)** and also conform with the requirements specified under:

a) *Making of chase* — The chase in the wall shall be neatly made and be of ample dimensions to permit the conduit to be fixed in the manner desired. In the case of buildings under construction, chases shall be provided in the wall, ceiling, etc at the time of their construction and shall be filled up neatly after erection of conduit and brought to the original finish of the wall. In case of exposed brick/rubble masonry work, special care shall be taken to fix the conduit and accessories in position along with the building work.

b) *Fixing of conduit in chase* — The conduit pipe shall be fixed by means of staples or by means of saddles not more than 600 mm apart. Fixing of standard bends or elbows shall be avoided, as far as practicable and all curves maintained by bending the conduit pipe itself with a long radius which will permit easy drawing-in of conductors. All threaded joints of rigid steel conduit shall be treated with preservative compound to secure protection against rust.

c) *Inspection boxes* — Suitable inspection boxes shall be provided to permit periodical inspection and to facilitate removal of wires, if necessary. These shall be mounted flush with the wall. Suitable ventilating holes shall be provided in the inspection box covers. The minimum sizes of inspection boxes shall be 75 mm × 75 mm.

d) *Types of accessories to be used* — All outlet, such as switches and wall sockets, may be either of flush mounting type or of surface mounting type, as given below:

    1) *Flush mounting type* — All flush mounting outlets shall be of cast-iron or mild steel boxes with a cover of insulating material or shall be a box made of a suitable insulating material. The switches and other outlets shall be mounted on such boxes. The metal box shall be efficiently earthed with conduit by a suitable means of earth attachment.

    2) *Surface mounting type* — If surface mounting type outlet box is specified, it shall be of any suitable insulating material and outlets mounted in an approved manner.

The switches/socket-outlets shall have adequate IP rating for various utilizations.

6.9.3 *Conduit Wiring System with Rigid Non-Metallic Conduits*

Rigid non-metallic conduits are used for concealed conduit wiring. This type of wiring system is more preferred for coastal areas.

6.9.3.1 *Type and size*

All non-metallic conduits used shall conform to accepted standards [D-2(45)] and shall be used with the corresponding accessories {*see* accepted standards [D-2(48)]}. The conduits shall be circular or rectangular cross sections.

6.9.3.2 *Bunching of cables*

Conductors of a.c. supply and d.c. supply shall be bunched in separate conduits. For lighting and small power outlet circuits phase segregation in separate circuits is recommended. The number of insulated cables that may be drawn into the conduits are given in Table 1B. In Table 1B, the space factor does not exceed 40 percent of the available space.

Table 1B Maximum Permissible Number of 250 V Grade Single-Core Copper Cables that may be Drawn into Rigid Non-Metallic Conduits

[*Clauses* 6.6.1(a) *and* 6.9.3.2]

Sl No.	**Sizes of Cable**	**Size of Conduit,** mm				
	Nominal Cross-Sectional Area mm^2	20	25	32	40	50
		Number of Cables, *Max*				
(1)	(2)	(5)	(6)	(7)	(8)	(9)

v)	10	–	4	7	9	–
vi)	16	–	2	4	5	12
vii)	25	–	–	2	2	6
viii)	35	–	–	–	2	5

6.9.3.3 *Conduit joints*

Conduits shall be joined by means of couplers. Where there are long runs of straight conduit, inspection type couplers shall be provided at intervals. For conduit fittings and accessories reference may be made to the accepted standard [D-2(48)].

6.9.3.4 *Fixing of conduit in chase*

The conduit pipe shall be fixed by means of stapples or by means of non-metallic saddles placed at not more than 600 mm apart or by any other approved means of fixing. Fixing of standard bends or elbows shall be avoided, as far as practicable and all curves shall be maintained by bending the conduit pipe itself with a long radius which will permit easy drawing in of conductors. At either side of bends, saddles/stapples shall be fixed at a distance of 150 mm from the centre of bends.

6.9.3.5 *Inspection boxes*

Suitable inspection boxes to the nearest minimum requirements shall be provided to permit periodical inspection and to facilitate replacement of wires, if necessary. The inspection/junction boxes shall be mounted flush with the wall or ceiling concrete. Where necessary deeper boxes of suitable dimensions shall be used. Suitable ventilating holes shall be provided in the inspection box covers, where required.

6.9.3.6 The outlet boxes such as switch boxes, regulator boxes and their phenolic laminated sheet covers shall be as per requirements of **6.9.1**(h). They shall be mounted flush with the wall.

6.9.3.7 *Types of accessories to be used*

All accessories such as switches, wall sockets, etc, may be either flush mounting type or of surface mounting type.

6.9.3.8 *Bends in conduits*

Wherever necessary, bends or diversions may be achieved by bending the conduits or by employing normal bends, inspection bends, inspection boxes, elbows or similar fittings. Heat may be used to soften the conduit for bending and forming joints in case of plain conduits.

6.9.3.9 *Outlets*

In order to minimize condensation or sweating inside the conduit, all outlets of conduit system shall be properly drained and ventilated, but in such a manner as to prevent the entry of insects.

6.10 Cable Trunking/Cable Ways

Cable trunking and ducting system of insulating material are used for laying of cables and wire both in floor and ceiling. The maximum number of cables with sizes that can be drawn in a cable trunking or ducting shall be limited to a maximum of 40 percent of space available.

7 FITTINGS AND ACCESSORIES

7.1 General

This covers the requirements of fittings and accessories which are normally used in fixed wiring installations of buildings. This includes type of light fixtures which are typically selected based on the requirement of light at a particular location and fans based on the requirement of air movement for the purpose of comfort of occupants, especially during hot summer months, and also of exhaust fans to maintain the enclosed area with fresh outside air so that a hygienic and comfortable atmosphere is created inside the enclosed area. For buildings other than small dwellings the requirement of lighting is normally selected based on the illumination level for different areas and that of the fans based on the type of occupancy and different comfort levels. The fittings and accessories shall comply with relevant Indian Standards and ISI marked (where mandated).

7.2 Ceiling Roses and Similar Attachments

A ceiling rose or any other similar attachments shall only be used as a final terminating point in single phase and voltage not exceeding 250 V.

Normally, only one flexible cord shall be attached to a ceiling rose. Specially designed ceiling roses shall be used for multiple pendants.

A ceiling rose shall not embody fuse terminal as an integral part of it.

7.3 Socket-Outlets and Plugs

There are two types of socket-outlets, one for the use of light loads not exceeding 100 W which are designated as 6 A and is normally provided with 3 pin socket-outlets in which both 3 pin plug tops and 2 pin appliances like mobile chargers can be used. This type of socket-outlet shall normally be kept on the switch board as well as individually at convenient heights not exceeding 1.2 m from the floor level based on requirement.

The second type of socket-outlets is normally of 16 A capacity and are provided with 6 pin socket-outlets in which 3 pin plug tops of 16 A capacity as well as smaller type 3 pin plug tops of about 10 A capacity can be used. These types of socket-outlets are recommended for use in respect of domestic appliances not exceeding 2 kW. These are normally placed independently at suitable heights and also above kitchen slab at appropriate level based on the requirement (*see* Fig. 4).

Each socket-outlet shall be controlled by a switch which shall preferably be located immediately adjacent thereto or combined therewith. The switch controlling the socket-outlet shall be on the live side of the line.

In respect of individual air conditioners, it is recommended to use MCB controlled socket-outlet so that proper overload protection can be maintained based on the capacity of air conditioner used which may not exceed 3 TR.

In case of public buildings, to facilitate operation of switches/socket-outlets by persons with disabilities and the elderly, these shall be installed at an accessible height for reaching and operating, between 800 mm and 1 100 mm above floor level and shall be located at a minimum of 600 mm with a preference of minimum 700 mm from any internal corner. They shall be so fixed so as to be away from danger of mechanical injury.

Suitable earth wire shall be drawn along with the power wiring for the respective socket-outlets so that the third pin is effectively earthed to ensure the equipment connected to the respective socket-outlet is properly earthed at the time of use.

NOTES

1 In situations where a socket-outlet is accessible to children, it is necessary to install an interlocked plug and socket or alternatively a socket-outlet which automatically gets screened by the withdrawal of plug. In industrial premises socket-outlet of rating 20 A and above shall preferably be provided with interlocked type switch.

2 As an exception, electrical wall socket-outlets, telephone points and TV sockets can be located at a minimum height of 400 mm above floor level.

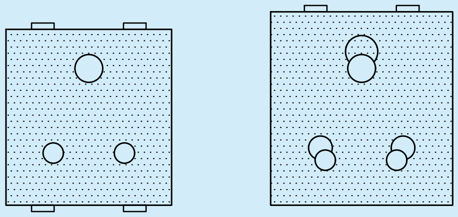

FIG. 4 6 A 3 PIN, 6/16 A COMBINED SOCKET-OUTLET

7.4 Light Fittings

7.4.1 *Lamp Holders*

There are different types of lamp holders namely pendant type, angle bracket type and batten mounted type lamp holders, each of which is further categorized as pin type and different sizes of screw type. These lamp holders are used in combination with different type of lamp shades to form ceiling suspended light fittings, wall mounted bracket type light fittings and chandelier type light fittings. These fittings can hold any of the GLS lamps of different wattage or CFL lamps and even the LED bulbs.

A switch shall be provided for control of every lighting fitting or a group of lighting fittings in the live wire. The neutral wire shall normally be looped in a light circuit. The earth wire of each point shall be used to earth the lamp holder or any such metallic point in the light fitting which does not carry electric current. Where control at more than one point is necessary, either two way or intermediate switches may be provided as required.

Shade made of flammable material shall not form a part of lighting fittings unless such shade is well protected against all risks of fire.

General and safety requirements for electrical lighting fittings shall be in accordance with provisions contained in good practice [D-2(1)] and relevant Indian Standards.

7.4.2 *Lamps*

All bare lamps including light fittings unless otherwise required and suitably protected, shall be hung at a height of not less than 2.4 m above the finished floor level. All electric lamps and accessories shall conform to relevant Indian Standards.

7.4.3 *Outdoor Lighting*

External street light fittings, bollards light fittings, bulk-head fittings, etc shall be weatherproof to prevent the ingress of moisture and dust effectively.

7.5 Fans, Regulators and Clamps

7.5.1 *Ceiling Fans*

Ceiling fans, including their suspension, shall conform to the relevant Indian Standards and good practice [D-2(1)]. There are two main types of ceiling fans available, the conventional type regular a.c. fans and the brushless direct current (BLDC) type fans which consume less power but may be expensive. Selection of the fans shall be on the basis of following technical parameters:

a) fan sweep, in mm (900/1 050/1 200/1 400/1 500);

b) air delivery, in m^3/min;

c) maximum power input, in w; and

d) service value, in m^3/min/W.

The bottom most point of the ceiling fan shall not be less than 2 400 mm above the finished floor level {*see* good practice [D-2(1)]}.

All ceiling fans shall meet the following requirements:

a) Control of a ceiling fan shall be through its own regulator as well as a switch in series.

b) All ceiling fans shall be wired with normal wiring to ceiling roses or to special connector boxes to which fan rod wires shall be connected and suspended from hooks or shackles with insulators between hooks and suspension rods. There shall be no joint in the suspension rod. The suspension rod shall be of adequate strength to withstand the dead and impact forces imposed on it. Suspension rods should preferably be procured along with the fan.

c) Fan hooks (clamp) shall be of suitable design according to the nature of construction of ceiling on which these clamps are to be fitted. In all cases fan clamps shall be fabricated from new metal of suitable sizes and they shall be as close fitting as possible. Fan clamps for reinforced concrete roofs shall be buried with the casting of roof and care shall be taken to tie the fan clamp with the reinforcement of the roof slab. Fan clamps for wooden beams shall be of suitable flat iron fixed on two sides of the beam, and according to the size and section of the beam one or two mild steel bolts passing through the beam shall hold both flat irons together. Fan clamps for steel joist shall be fabricated from flat iron to fit rigidly to the bottom flange of the beam. *See also* good practice [D-2(1)]. Care shall be taken during fabrication that the metal does not crack while hammer to shape. Other fan clamps shall be made to suit the position, but in all cases, care shall be taken to see that they are rigid and safe.

d) Canopies on top and bottom of suspension rods shall effectively conceal suspensions and connections to fan motors, respectively.

e) The lead-in-wire shall be of nominal cross-sectional area, not less than 1.5 mm^2 copper and shall be protected from abrasion.

f) Unless otherwise specified, the clearance between the bottom most point of the ceiling fan and the floor shall be not less than 2.4 m. The minimum clearance between the ceiling and the plane of the blades shall be not less than 300 mm.

A typical arrangement of a fan clamp is given in Fig. 5.

NOTE — All fan clamps shall be so fabricated that fans revolve steadily.

Fig. 5 Typical Design of Fan Clamps

7.5.2 *Exhaust Fans*

Exhaust fans are necessary for spaces, such as community toilets, kitchens and canteens and godowns to provide the required number of air changes (*see* Part D 'Building Services, Section 3 Air Conditioning, Heating and

Mechanical Ventilation' of this NBCS). Since the exhaust fans are located generally on the outer walls of a room, appropriate openings in such walls shall be provided for, in the planning stage.

NOTE — Exhaust fan requirement is based on the recommended air changes (*see* Part D 'Building Services, Section 3 Air Conditioning, Heating and Mechanical Ventilation' of this NBCS). Reference should also be made to Part F 'Fire and Life Safety' of this NBCS for exhaust fan requirements for smoke extraction.

Selection of exhaust fan can be made on the basis of:

a) blade sweep size in mm;
b) air changes in CFM or m^3/min; and
c) power input in W.

For fixing of an exhaust fan, a circular hole shall be provided in the wall to suit the size of the frame which shall be fixed by means of rag-bolts embedded in the wall. The hole shall be neatly plastered with cement and brought to the original finish of the wall. The exhaust fan shall be connected to exhaust fan point which shall be wired as near to the hole as possible by means of a flexible cord, care being taken that the blades rotate in the proper direction.

7.5.3 *Air Circulation* (*Ceiling Fans*)

7.5.3.1 Proper air circulation of rooms and halls of residential buildings/office can be achieved by suitable selection of ceiling fans based on their size and air displacement. In big halls, this can be done either by larger number of smaller fans or smaller number of larger fans. The economics of the system as a whole should be a guiding factor along with the bays of the building. For design guidelines in this regard, reference shall be made to Part D 'Building Services, Section 1 Lighting and Natural Ventilation' of this NBCS and good practice [D-2(1)].

7.5.3.2 Where ceiling fans are provided, the bay sizes of a building, which control fan point locations, play an important part. Fans of 1 200 mm/1 400 mm sweep normally cover an area of 9 m^2 to 10 m^2, for every part of a bay to be served by the ceiling fans, it is necessary that the bays shall be so designed that full number of fans can be suitably located for the bay, otherwise it will result in ill-ventilated pockets. In general, fans in long halls may be spaced at 3 m in both the directions. If building modules do not lend themselves for proper positioning of the required number of ceiling fans, other fans such as, air circulators or bracket fans will have to be employed for the areas uncovered by the ceiling fans. For this, suitable electrical outlets shall be provided although result may be disproportionate to cost on account of fans.

7.5.3.3 High volume low speed (HVLS) fans are generally ceiling fans having more number of blades which move slowly and distribute large amounts of air at low rotational speed. These are installed in very large areas like airports, hangers, warehouses and in commercial spaces like malls, etc, which have very big area with large movement of people. These are primarily recommended for bigger areas from the consideration of energy conservation.

7.5.3.4 Nowadays BLDC type fans having low wattage and higher air displacement are available with remote control operation. Choice of the same may be decided based on their operational efficiency in relation to cost.

7.6 Interchangeability

Similar parts of all switches, lamp holders, distribution fuse-boards, ceiling roses, brackets, pendants, fans and all other fittings shall be so chosen that they are of the same type and interchangeable in each installation.

7.7 Equipment

7.7.1 Electrical equipment which form integral part of wiring intended for switching or control or protection of wiring installations shall conform to the relevant Indian Standards, wherever they exist.

7.7.2 Positioning of fans and light fittings shall be chosen to make these effective without causing shadows and stroboscopic effect on the working planes.

8 EARTHING

8.1 General

8.1.1 Earthing is an important part of any electrical installation. It is essential to provide safety of human beings from electrical shock. It is also necessary to prevent fire from electrical fault and to operate the protective devices to disconnect power during an electrical fault and to ensure safe operation of the equipment. Earthing is therefore meant to divert the fault current to the protective earth conductor without causing any major damage to the installations. Thus earthing/earth conductor (also known as a ground conductor or earthing conductor) is a safety feature in electrical systems which provides a low-impedance path to the earth and helps to prevent hazardous voltages from appearing on equipment ensuring that faults are cleared quickly. In principle, it acts as a safeguard, protecting both people and equipment from electrical hazards. With the proliferation in electrical/electronic gadgets and greater dependency on voice and data communication systems, proper and effective earthing or grounding is very important. Earthing is also necessary for safe dissipation of the effects of lightning strikes from the buildings and its contents, including from sensitive equipment. All works under earthing shall comply with the provisions of good practice [D-2(1)] and [D-2(11)] apart from other Indian Standards, where applicable.

8.1.2 Different types of earth electrodes and different types of earthing systems are available. For low voltage and high voltage systems which apply to almost all electrical systems of buildings, the common earthing system followed is with the neutral solidly earthed at the source. This system requires that there is always a protective earth continuity conductor running all through the system and all metal parts of electrical appliances connected to an electrical system are connected to the earth continuity conductor. The exception to this system is the double insulated appliances which are connected to the line and neutral and operate on low voltage (single phase) and are also of low power consumption. All appliances (other than double insulated devices) use the earthing through the earth continuity conductor. Single phase appliances use a 3 wire connection with line (live wire), neutral (return path wire) and the earth-wire. Three phase appliances use a connection with 4 wires for a load which does not require a neutral connection or use a 5 wire connection if the appliance requires a neutral connection. Care should be taken to ensure that the earthing system, the protective earth conductor and the earthing pin of the socket-outlets are not disconnected.

8.1.3 Different earthing systems have features which are suitable for different applications. Earthing system adopted should be so selected so as to match with the type of load, protection device, application, degree of reliability, etc. For classification of electrical systems based on the relationship of the source and of exposed-conductive parts of the installation, to earth, *see* **2.1.185**.

8.1.4 *System Earthing*

Earthing of system is designed primarily to preserve the security of the system by ensuring that the potential on each conductor is restricted to a value consistent with the level of applied insulation. It is equally important that earthing should ensure efficient and fast operation of protective gear in the case of earth faults.

a) *TN system* — A system having one or more points of the source of energy directly earthed, the exposed conductive-parts of the installation being connected to that point by protective conductors. This is divided into TN-C system, TN-S system and TN-C-S system which are described below:

   1) *TN-C system* — A system in which neutral and protective conductors are combined in a single conductor throughout the system. This is normally provided at their source by the electrical supply company in single phase two wire or three phase four wire system.

   2) *TN-S system* — A system having separate neutral and protective conductor throughout the system. This is provided by the consumer at the point of receipt of electric supply.

   3) *TN-C-S system* — A system in which neutral and protective conductors are combined in a single conductor in part of the system. It involves a shared neutral and earth conductor from the source up to the consumer's intake, where it is then separated into individual neutral (N) and protective earth (PE) conductors.

b) *TT system* — A system having one point of the source of energy directly earthed, the exposed-conductive-parts of the installation being connected to the earth electrodes electrically independent of the earth electrodes of the source.

c) *IT system* — A system in which all live parts are isolated from earth or point connected to earth through high impedance. The exposed-conductive-parts of the electrical installation are earthed independently or collectively to the earthing of the system. This system is mostly used in hospitals, sensitive areas and places where stable power supply is essential for critical loads.

8.2 Selection and Design of Earthing System

8.2.1 Earthing shall generally be carried out in accordance with the requirements of Regulation 18, 43 and 50 of *Central Electricity Authority* (*Measures Relating to Safety and Electric Supply*) *Regulations*, 2023 (*see* Annex B), relevant Indian Standards and the relevant regulations of the Electricity Supply Authority concerned. All materials, fittings, etc used in earthing shall conform to relevant Indian Standard specification.

8.2.2 Conductors and earth electrodes in an earthing system shall be so designed and constructed that in normal use their performance is reliable and without danger to persons and surrounding equipment. Earthing system shall be designed so as to have touch potential, step potential and transfer potential within the specified limits as indicated in good practice [D-2(18)] and [D-2(11)] as amended up to date. The choice of a material depends on its ability to match the particular application requirement. The requirements for earthing arrangements are intended to provide a connection to earth which:

a) is reliable and suitable for the protective requirements of the installation;

b) can carry earth fault currents and protective conductor currents to earth without danger from thermal, thermo-mechanical and electromechanical stresses and from electric shock arising from these currents;

c) if relevant, is also suitable for functional requirements; and

d) is suitable for the foreseeable external influences as provided in good practices [D-2(1)], [D-2(18)], [D-2(11)] and IEC 60364-5-51 : 2005 'Electrical installations of buildings — Part 5-51: Selection and erection of electrical equipment — Common rules', for example, mechanical stresses and corrosion.

8.2.3 The main earthing system of an electrical installation shall consist of:

a) an earth electrode (electrode can be vertical rod/pipe/buried plate or an earth mat with several vertical installations or a ring earthing strip/conductor);

b) a main earthing wire;

c) main earthing terminal (MET), an earth bar (located on the main switchboard for small installation and installed in the wall/room in case of large industrial electronic installations) for the connection of the main earthing wire, protective earthing wires and/or bonding wires within the installation; and

d) a removable link, which effectively disconnects the neutral bar from the earth bar.

NOTE — The requirements of (c) and (d) above shall be carried out by a licensed electrician as part of the switchboard installation.

8.2.4 The main earthing wire connection shall:

a) be mechanically and electrically sound;

b) be protected against damage, corrosion, and vibration;

c) not place any strain on various parts of the connection;

d) not damage the wire or fittings; and

e) be secured at the earth electrode.

8.2.4.1 The main earthing wire termination shall be readily accessible at the earth electrode except for **8.2.22**. As far as possible, all earth connections, except exothermically welded, shall be visible for inspection.

8.2.5 Consideration shall be given to the earthing arrangements where currents with high frequencies are expected to flow {*see* good practice [D-2(18)] and IEC 60364-4-44 : 2007 'Low-voltage electrical installations — Part 4-44: Protection for safety — Protection against voltage disturbances and electromagnetic disturbances'}.

8.2.6 Protection against electric shock {*see* good practice [D-2(18)] and IEC 60364-4-41: 2005 'Low-voltage electrical installations — Part 4-41: Protection for safety — Protection against electric shock'}, shall not be adversely affected by any foreseeable change of the earth electrode resistance (for example, due to corrosion, drying or freezing).

8.2.7 Where the supply to an installation is at high or extra high voltage, requirements concerning the earthing arrangements of the high or extra high voltage supply and of the low-voltage installation shall also comply with provisions of good practice [D-2(18)] and IEC 60364-4-44 : 2007 'Low-voltage electrical installations — Part 4-44: Protection for safety — Protection against voltage disturbances and electromagnetic disturbances'.

8.2.8 A permanent fitting (like a screwed-down label, or one that can be threaded onto the cable) shall be used at the connection point that is clearly marked with the words: 'EARTHING LEAD — DO NOT DISCONNECT' or 'EARTHING CONDUCTOR — DO NOT DISCONNECT'.

8.2.9 All low voltage, three phase equipment shall be earthed by two separate and distinct connections with earth. In case of single phase equipment, single distinct earth connection is sufficient. The contact area of earth conductor/plate shall be determined in accordance with good practice [D-2(11)].

8.2.9.1 The 415/240 V, 4 wire, 3 phase systems are normally operated with the neutral solidly earthed at source. At low voltage, the Central Electricity Authority regulations require that the neutral be earthed by two separate and distinct connections with earth. Neutral of transformers of 33 kV/415 V, 11 kV/415 V and neutral of low voltage DG sets and similar equipment shall be of the same size as the phase conductor or higher as per relevant Indian Standard.

NOTE — Neutral conductor of half the size of the phase conductor was permitted in earlier installations. But with the proliferation of equipment using non-linear devices and consequent increase in harmonics, the neutral will carry a current more than the notional out-of-balance current and therefore neutral conductor shall be of the same size as the phase conductor.

8.2.10 In the case of high and extra high voltages, the neutral points shall be earthed by not less than two separate and distinct connections to earth, each having its own electrode at the generating station or substation and may be earthed at any other point, provided no interference is caused by such earthing. The neutral may be earthed through suitable impedance. Neutral earthing conductor shall be sized as to have a current carrying capacity not less than the phase current.

8.2.11 For industrial/commercial installations having a transformer within the facility, soil resistivity of the place of installation shall be measured and recorded {*see* good practice [D-2(11)]}. For the adopted type of earth electrode configuration, earth fault impedance of the configuration shall be calculated and recorded {*see* good practice [D-2(11)]}.

8.2.12 It is recommended that a drawing showing the main earth connection and earth electrodes be prepared for each installation.

8.2.13 Earth system shall be so devised that the testing of individual earth electrode is possible. It is recommended that the value of any earth system resistance shall be such as to conform to the degree of shock protection desired. For measuring purposes, the joint shall be capable of being opened with the aid of a tool. In normal use it shall remain closed. Inclusion of online earth monitoring system with real time earthing grid resistance and integrity measurement at site level can be considered for buildings which house lot of sensitive systems and also number of electronic devices to ensure human safety and equipment protection.

8.2.14 Conductors, other than live conductors and any other parts intended to carry a fault current, shall be capable of carrying that current without attaining an excessive temperature.

8.2.15 No addition to the current carrying system, either temporary or permanent, shall be made which will increase the maximum earth fault current or its duration until it has been ascertained that the existing arrangement of earth electrodes, earth busbar, etc are capable of carrying the new value of earth fault current which may be obtained by this addition.

8.2.16 No cut-out, link or switch other than a linked switch arranged to operate simultaneously on the earthed conductor or earthed neutral conductor and the live conductors, shall be inserted on any supply system. This, however, does not include the case of a switch used in controlling a generator or a transformer or a link for test purposes.

8.2.17 The number of connections along the conductors shall be minimized to reduce potential failure points. The high energy lightning currents can induce significant thermal expansion, if bonding is inadequate and overlap is poor. Also, mechanical connections should be minimized. All conductors used in earthing and lightning protection system should be joined using methods that ensure long-term electrical, mechanical and environmental reliability. Critical connections, especially those below ground or exposed to moisture shall be made using exothermic welding which provides a permanent molecular bond with superior thermal and corrosion resistance. Exothermic welded joints shall conform to the relevant standards.

8.2.18 Earthing associated with current-carrying conductor is normally essential for the function of the system and is generally known as system earthing or functional earthing, while earthing of non-current carrying metal work and conductor is essential for the safety of human life, animals and of property and it is generally known as equipment earthing or equipotential bonding. The requirements for protective purposes shall always take precedence.

8.2.19 *Equipotential Bonding*

Equipotential bonding is through connecting exposed and extraneous conductive parts in a building to the main earthing terminal of the installation by protective bonding conductors. Where such conductive parts originate outside the building, they shall be bonded near their entry point within the building.

It shall be ensured that all exposed metal parts and extraneous conductive parts within a specific area or system are at the same potential. The same is achieved by creating a low resistance path between these conductive parts. Equipotential bonding allows fault currents to flow to earthed conductor without creating dangerous voltage difference that could harm individuals.

Equipotential bonding is used in various settings including buildings, industrial facilities, swimming pools and areas with lightning protection system. In the event of a fault equipotential bonding helps limit touch voltages and ensures that fault currents are safely directed to earth preventing electric shock (*see* Fig. 6).

8.2.20 All earthing systems in a building shall be interconnected at the earth level (ground).

8.2.21 For selection of electrodes for use in corrosive environments, reference shall be made to good practice [D-2(11)].

8.2.22 Test joints are not required in the case of natural down-conductors combined with foundation earth electrodes (*see* Fig. 7).

8.2.23 For computer and other sensitive electronic equipment system in industrial and commercial application, special bonding techniques with isolation transformer can be employed (*see* Fig. 8).

8.2.24 Isolated earthing is unsafe during a transient condition. In unavoidable conditions if isolated earthing is used to reduce potential difference between isolated earthing, earth couplers or isolating spark gaps shall be installed. This will reduce potential difference during a transient condition such as lightning.

KEY

1 MAIN EQUIPOTENTIAL BONDING (CONNECTION BETWEEN MET AND EXTRANEOUS CONDUCTIVE PARTS).

2 MAIN EQUIPOTENTIAL BONDING CONDUCTOR (INDIVIDUAL CONNECTION, NO LOOPING). IN CASE OF LARGE NUMBER OF EXTRANEOUS CONDUCTIVE PARTS, AN EARTHING TERMINAL CAN BE LOCATED NEAR THE EXTRANEOUS CONDUCTIVE PARTS FOR INDIVIDUAL CONNECTION TO THESE PARTS AND A COMMON CONNECTION FROM THIS EARTHING TERMINAL TO MET. SUITABLE INDICATIONS SHALL BE MADE TO EVERY CONNECTION OF EQUIPOTENTIAL BONDING CONDUCTOR TO AVOID ACCIDENTAL DISCONNECTIONS.

3 EARTHING CONDUCTOR. (CONNECTS MET AND EARTHED POINT OF THE SOURCE IN TN SYSTEM OR MET AND EARTH ELECTRODE IN CASE OF TT/IT SYSTEM). ONE CONNECTION FROM MET IS ALSO NECESSARY TO LPS (IF INSTALLED).

4 PROTECTIVE EARTHING BY PROTECTIVE EARTHING CONDUCTOR (PE).

5 SUPPLEMENTARY EQUIPOTENTIAL BONDING TERMINAL (SEBT) (TO RE DUCE TOUCH VOLTAGE < 50 V).

6 SUPPLEMENTARY EQUIPOTENTIAL BONDING CONDUCTOR.

1 EARTH BRANCH CIRCUIT SHALL HAVE A SEPARATE NEUTRAL AND EARTH WIRE. NO DAISY CHAINING PERMITTED.

2 ONLY COMPUTER OR CONTROL SYSTEM SHOULD BE SERVED FROM THIS PANEL.

FIG. 8 RECOMMENDED POWER DISTRIBUTION FOR A COMPUTER AND CONTROL SYSTEM WITH A DELTA/STAR ISOLATION TRANSFORMER

8.3 Earth Electrodes

The efficacy of any earth electrode depends on its configuration and upon local soil conditions. Number of earth electrodes suitable for the soil conditions and the value of resistance to earth as well as earth fault impedance shall be considered. It is essential that earthing conductors of the earth system shall follow the provisions as per good practice [D-2(1)] read with good practice [D-2(11)] in view of provisions in CEA Regulation No. 43 (*see* Annex B) regarding earth fault loop impedance. Examples of earth electrodes which may be used are:

a) concrete-embedded foundation earth electrode;

b) soil-embedded foundation earth electrode;

c) metallic electrode embedded directly in soil vertically or horizontally (for example rods, wires, tapes, pipes or plates);

d) metal sheath and other metal coverings of cables according to local conditions or requirements;

e) other suitable underground metalwork (for example pipes) according to local conditions or requirements; and

f) welded metal reinforcement of concrete (except pre-stressed concrete) embedded in the earth.

The type, materials and dimensions of earth electrodes shall be selected to withstand corrosion and to have adequate mechanical strength for the intended lifetime. For materials commonly used for earth electrodes, the minimum sizes, from the point of view of corrosion and mechanical strength, when embedded in the soil or in concrete, shall be as specified in Table 2. In the case of lightning protection system, the provisions of **11.6.3** shall also be complied with.

NOTES

1 For corrosion, the parameters to be considered are: the soil *p*H at the site, soil resistivity, soil moisture, stray and leakage a.c. and d.c. current, chemical contamination, and proximity of dissimilar materials.

2 The minimum thickness of protective coating is greater for vertical earth electrodes than for horizontal earth electrodes because of their greater exposure to mechanical stresses while being embedded.

3 Interconnection of dissimilar metals should be avoided in earthing systems and earth conductors to prevent corrosion and loose connections.

Earth electrode either in the form of solid rod, pipe, plate or earth grid should be provided at all premises for providing an earth system. Details of typical pipe, rod and plate earth electrodes are given in Fig. 9 and Fig. 10. Other electrode configurations can be as in Fig. 11 {*see* good practice [D-2(11)]}.

Although electrode material does not affect initial earth resistance, care should be taken to select a material which is resistant to corrosion in the type of soil in which it is used. In case where soil condition leads to excessive corrosion of the electrode and the connections, it is recommended to use either copper/stainless steel or copper coated steel electrode and copper/stainless steel connections. Exothermic welding may also be adopted to have enhanced life and strength to the connection. It is recommended to use similar material for earth electrodes and earth conductors or otherwise precautions should be taken to avoid corrosion. As an alternate, 50 mm GI earth strip and 100 mm CI pipe can be provided as per good practice [D-2(11)].

---

[1] As per Table B-1 under Part 1 'General and Common Aspects, Section 18: Earthing' of good practice [D-2(1)].

[2] The coating shall be smooth, continuous and free from flux stains.

[3] As rolled strip or slit strip with round edges.

[4] Chromium ≥ 16 percent, nickel ≥ 5 percent, molybdenum ≥ 2 percent, carbon ≤ 0.08 percent.

[5] Where experience shows that the risk of corrosion and mechanical damage is extremely low, 16 mm^2 can be used.

[6] This thickness is provided to withstand mechanical damage of copper coating during the installation process. It may be reduced to not less than 100 µm where special precautions to avoid mechanical damage of copper during the installation process (for example, drilling holes or special protective tips) are taken according to the manufacturer's instruction.

NOTES

1 Values in bracket are applicable for protection against electric shock only, while values not in brackets are applicable for lightning protection and for protection against electric shock.

2 Metals inserted inside pipe will not influence in the final earth resistance value.

3 Unprotected ferrous materials are not recommended due to high corrosion (*see* IEC 60364-4-43 : 2008 'Low-voltage electrical installations — Part 4-43: Protection for safety — Protection against overcurrent').

FIG. 11 MISCELLANEOUS ELECTRODE CONFIGURATIONS

8.4 Earth Enhancing Compound

Multiple rods, even in large numbers, may sometime fail to produce an adequately low resistance to earth. This condition arises in installations involving soils of high resistivity. The alternative is to reduce the resistivity of the soil immediately surrounding the earth electrode. To reduce the soil resistivity, artificial soil treatment shall be adopted.

8.4.1 Earthing enhancing compound is a conductive compound producing low resistance of an earth-termination system. These compounds used for artificial treatment of soil shall satisfy the requirements as per accepted standard [D-2(49)].

8.4.2 The material of the earthing enhancing compound shall be chemically inert to subsoil. It shall not pollute the environment. It shall provide a stable environment in terms of physical and chemical properties and exhibit low resistivity. The earthing enhancing compound shall not be corrosive to the earth electrodes being used. The usage of earth enhancing compound shall adhere to the conditions detailed in accepted standard [D-2(49)].

8.4.3 The materials used for artificial treatment should also fulfil toxicity characteristic leaching procedure (TCLP) requirements.

8.4.4 Use of salt [sodium chloride (NaCl)] for artificial treatment of soil should be avoided as it accelerates corrosion of ferrous materials.

8.4.5 The requirement and use of earth enhancing compound shall comply with the provisions as per accepted standard [D-2(49)].

8.5 Earth Electrode Inspection Housings and Earth Electrode Seals

8.5.1 *Earth Electrode Inspection Housing*

Earth electrode inspection housing is the metallic or non-metallic enclosure that houses the down-conductor/earth-termination connection for inspection and testing purposes and consists of a housing and a removable lid. The design of the earth electrode inspection housing shall be such that it carries out its function of enclosing the down-conductor/earth rod termination in an acceptable and safe manner, and has sufficient internal dimensions to permit the assembly/disassembly of the earth rod clamp. The material of the earth electrode inspection housing shall be compatible with its surrounding environment and shall comply with the tests given in accepted standard [D-2(50)]. The work shall also comply with the provisions of good practice [D-2(11)].

8.5.2 *Earth Electrode Seal*

Water pressure seal used in conjunction with an earth rod electrode shall be such that there will be no effect on the water proofing treatment for the foundation of the building. The design of the earth electrode seal shall be such that it carries out its function of preventing ground water bypassing the earth rod and entering the basement of a building, in an acceptable and safe manner and shall be compatible with its surrounding environment and comply with the tests given in accepted standard [D-2(50)].

8.6 Bonding and Inter Connection

All connections made in an earthing system above or below ground should meet electrical conductivity, corrosion resistance, current carrying capacity and mechanical strength of the conductor. These connections should be strong enough to maintain a temperature rise below that of the conductor and to withstand the effect of heating and the mechanical forces caused by fault currents. Consideration shall be given to electrolytic corrosion when using different materials in an earthing arrangement. The complete connections shall be able to resist corrosion for the intended life of the installation.

8.6.1 For external conductors (for example, earthing conductor) connected to a concrete-embedded foundation earth electrode, the connection made from hot-dip galvanized steel shall not be embedded in the soil.

8.6.2 Where an earth electrode consists of parts that should be connected together, the connection shall be by exothermic welding, pressure connectors, clamps or other suitable mechanical connectors.

8.6.3 All connection components shall meet the requirements according to accepted standard [D-2(51)] and also provisions of good practice [D-2(11)] and [D-2(1)] where applicable.

8.7 Equipment and Portions of Installations which shall be Earthed

8.7.1 *Equipment to be Earthed*

Except for equipment provided with double insulation, all the non-current carrying metal parts of electrical installations are to be earthed properly. All metal conduits, trunking, cable sheaths, switchgear, distribution fuse boards, lighting fittings and all other parts made of metal shall be bonded together and connected by means of two separate and distinct conductors to an efficient earth electrode.

8.7.2 *Structural Metal Work*

Earthing of metallic parts of the structure shall be done according to good practice [D-2(11)].

8.8 Neutral Earthing

To comply with relevant Central Electricity Authority regulations, no fuses or circuit breakers other than a linked circuit breaker shall be inserted in an earthed neutral conductor. A linked switch or linked circuit breaker shall be arranged to break the neutral either with or after breaking all the related phase conductors. This shall make (or close) the neutral before making (or closing) the phases.

If this neutral point of the supply system is connected permanently to earth, then the above rule applies throughout the installation including 2 wire final circuits. This means that no fuses may be inserted in the neutral or common return wire. And the neutral should consist of a bolted solid link or part of a linked switch, which completely disconnects the whole system from the supply. This linked switch shall be so arranged that the neutral makes before and break after the phases. For further details, reference should be made to good practice [D-2(11)].

8.9 System of Earthing

Equipment and portions of installations shall be deemed to be earthed only if the earthing is done as per TN-S system with equipotential bonding as required. In all cases, the relevant provisions of the Central Electricity Authority regulations shall be complied along with provisions under good practice [D-2(11)].

8.10 The earthing of electrical installations for non-industrial and industrial buildings shall be done in accordance with good practice [D-2(11)] and good practice [D-2(1)].

9 INSPECTION, TESTING, VERIFICATION AND COMMISSIONING OF INSTALLATION

9.1 General Requirements

9.1.1 Before the completed installation, or an addition to the existing installation, is put into service, inspection and testing shall be carried out in accordance with the *Central Electricity Authority* (*Measures Relating to Safety and Electric Supply*) *Regulations*, 2023, with special reference to Regulation numbers 5, 8, 14, 17, 18, 20, 21, 29 to 39, 42, 43, 46 to 48 and 50 (*see* Annex B), and also as per provisions in Part 1 'General and common aspects, Section 17 Erection and pre-commissioning — Testing of installations' of good practice [D-2(1)]. In the event of defects being found, these shall be rectified, as soon as practicable and the installation retested.

9.1.2 Initial and periodic inspection and testing shall be carried out in order to maintain the installation in a sound condition after putting into service. The periodicity shall be as per provisions in Annex E under Part 1 'General and common aspects, Section 17 Erection and pre-commissioning — Testing of installations' of good practice [D-2(1)].

9.1.3 Where an addition is to be made to the fixed wiring of an existing installation, the latter shall be examined for compliance with the recommendations of this NBCS.

9.1.4 The individual equipment and materials which form part of the installation shall generally conform to the relevant Indian Standard, wherever applicable. If there is no relevant Indian Standard for any item, these shall be approved by the appropriate authority.

9.1.5 *Completion Drawings*

On completion of the electric work, a wiring diagram shall be prepared and submitted to the Engineer-in-Charge or the owner. All wiring diagrams shall indicate clearly the main switch board, the runs of various mains and submains cables and the position of all points and their controls. All circuits shall be clearly indicated and numbered in the wiring diagram and all points shall be given the same number as the circuit in which they are electrically connected. Also the location and number of earth points and the run of each loads should be clearly shown in the completion drawings.

9.1.6 *Inspection and Testing*

The substations and other electrical installations shall be checked and tested as detailed in **4.2** and **4.3** under Part 1 'General and common aspects, Section 17 Erection and pre-commissioning — Testing of installations' of good practice [D-2(1)] and necessary test reports shall be prepared in the prescribed proforma therein. In addition, additional checks and tests as mentioned under the **9.2** and **9.3** shall also be carried out if not included in good practice [D-2(1)]. In case any defects are noticed, the same shall be rectified, retested and their test format shall be completed.

9.2 Inspection of the Installation

9.2.1 *General*

On completion of wiring a general inspection shall be carried out by competent personnel in order to verify that the provisions of this NBCS and that of *Central Electricity Authority* (*Measures Relating to Safety and Electric Supply*) *Regulations*, 2023 have been complied with. This, among other things, shall include checking whether all equipment, fittings, accessories, wires/cables used in the installation are of adequate rating and quality to meet the requirement of the load. General workmanship of the electrical wiring with regard to the layout and finish shall be examined for neatness that would facilitate easy identification of circuits of the system, adequacy of clearances, soundness, contact pressure and contact area. A complete check shall also be made of all the protective devices, with respect to their ratings, range of settings and co-ordination between the various protective devices. It is preferable to have a third party inspection to maintain quality assurance.

9.2.2 *Items to be Inspected*

All equipment in a substation including HV panel, transformer, LV panel, emergency DG sets, battery bank, cables, cable terminations, etc need inspection. Healthiness of the main distribution boards, metering panels, distribution cables, rising mains, bus ducts, etc need to be verified along with earthing system. In case of provisions of rooftop solar PV system and other services, the equipment connected therein shall also be included in the items to be inspected.

9.2.2.1 *Substation installations*

In substation installation, it shall be checked whether:

a) the installation has been carried out in accordance with the approved drawings;

b) phase to phase and phase to earth clearances are provided as required;

c) all equipment are efficiently earthed and properly connected to the required number of earth electrodes;

d) HV and LV switchgears are all vermin and damp-proof and all unused openings or holes are blocked properly;

e) the required ground clearance to live-terminals is provided;

f) suitable fencing is provided (with gate, lockable arrangements) and suitably earthed as required;

g) there is no vegetation in outdoor substation;

h) the required number of caution boards, firefighting equipment, operating rods, insulation mats of appropriate rating, etc, are kept in the substation;

j) in case of indoor substation sufficient ventilation and draining arrangements are made;

k) all cable trenches are provided with non-inflammable covers;

m) free accessibility is provided for all equipment for normal operation;

n) all name plates are fixed and the equipment are fully painted;

p) all construction materials and temporary connections are removed;

q) oil-level, busbar tightness, transformer tap position, etc are in order;

r) earth pipe troughs and cover slabs are provided for earth electrodes/earth pits and the neutral earth pits and earth pits of lightning protection system are marked for easy identification;

s) earth electrodes are of GI pipes or CI pipes or copper plates or Cu bonded rods as per Table 2 and, for earth connections, brass bolts and nuts with lead washers are provided in the pipes/plates;

t) earth pipe troughs and oil sumps/pits are free from rubbish and dirt and stone jelly, and the earth connections are visible and easily accessible;

u) earthing system designed are periodically checked for permissible limits of step and touch potential;

w) the earth busbars have tight connections and corrosion-free joint surfaces;

y) operating handle of protective device are provided at an accessible height from ground, that is, 300 mm to 1 800 mm;

z) adequate headroom is available in the transformer room for easy topping-up of oil, maintenance, etc;

aa) safety devices, horizontal and vertical barriers, busbar covers/shrouds, automatic safety shutters/doors interlock and handle interlock are safe and in reliable operation in all panels and cubicles;

bb) clearances in the front, rear and sides of the main HV, LV and sub-switch boards are adequate;

cc) the switches operate freely, the 3 blades make contact at the same time, the arcing horns contact in advance, and the handles are provided with locking arrangements;

dd) insulators are free from cracks, and are clean;

ee) in oil cooled transformers, leakage of oil, if any should be checked;

ff) connections to bushing in transformers are tight and have good contact;

gg) bushings are free from cracks and are clean;

hh) accessories of transformers like breathers, vent pipe, buchholz relay, etc, are in order;

jj) connections to gas relay in transformers are in order;

kk) oil and winding temperature are set for specific requirements in transformers;

mm) in case of cable cellars, adequate arrangements made to pump out water that has entered due to seepage or other reasons;

nn) all incoming and outgoing circuits of HV and LV panels are clearly and indelibly labelled for identification;

pp) no cable is damaged;

qq) there is adequate clearance around the equipment installed; and

rr) cable terminations are proper.

9.2.2.2 *High/low voltage installation*

In high and low voltage installations, it shall be checked whether:

a) all blocking materials that are used for safe transportation in switchgears, contactors, relays, etc are removed;

b) all connections to the earthing system are feasible for periodical inspection;

c) sharp cable bends are avoided and cables are taken in a smooth manner in the trenches or alongside the walls and ceilings using suitable support clamps at regular intervals;

d) suitable circuit breaker or lockable push button is provided near the motors/apparatus for controlling supply to the motor/apparatus in an easily accessible location;

e) two separate and distinct earth connections are provided for the motor/apparatus;

f) control switch-fuse is provided at an accessible height from ground for controlling supply to overhead travelling crane, hoists, overhead busbar trunking;

g) the metal rails on which the crane travels are electrically continuous and earthed and bonding of rails and earthing at both ends are done;

h) four core cables are used for overhead travelling crane and portable equipment, the fourth core being used for earthing, and separate supply for lighting circuit is taken;

j) if flexible metallic hose is used for wiring to motors and other equipment, the wiring is enclosed to the full lengths, and the hose secured properly by approved means;

k) the cables are not taken through areas where they are likely to be damaged or chemically affected;

m) the screens and armours of the cables are earthed properly;

n) the belts of the belt driven equipment are properly guarded;

p) adequate precautions are taken to ensure that no live parts are so exposed as to cause danger;

q) ammeters and voltmeters are tested;

r) the relays are inspected visually by removing covers for deposits of dusts or other foreign matter;

s) wherever bus ducts/rising mains/overhead bus trucking are used, special care being taken for earthing the system, and all tap off points are provided with adequately rated protective device like MCB, MCCB, fuses, RCCB/RCD, SPD (*see* **11**), etc;

t) all equipment are weather, dust and vermin proof; and

u) any and all equipment having air insulation as media maintain proper distances between phases, phase to neutral, phase to earth and earth to neutral.

9.2.2.3 *Overhead lines*

For overhead lines, it shall be checked whether:

a) all conductors and apparatus including live parts thereof are inaccessible;

b) the types and size of supports are suitable for the overhead lines/conductors used and are in accordance with approved drawing and standards;

c) clearances from ground level to the lowest conductor of overhead lines, sag conditions, etc, are in accordance with the relevant Indian Standards and the CEA Regulations;

d) where overhead lines cross the roads or cross each other or are in proximity with one another, suitable guarding is provided at road crossings and to also protect against possibility of the lines coming in contact with one another;

e) every guard wire is properly earthed;

f) the type, size and suitability of the guarding arrangement provided is adequate;

g) stays are provided suitably on the overhead lines, as required and are efficiently earthed or provided with suitable stay insulators of appropriate voltages;

h) anti-climbing devices and danger board/caution board notices are provided on all HV supports;

j) clearances along the route are checked and all obstructions, such as, trees/branches and shrubs are cleared on the route to the required distance on either side;

k) clearance between the live conductor and the earthed metal parts are adequate;

m) for the service connections tapped-off from the overhead lines, cut-outs of adequate capacity are provided;

n) all insulators are properly and securely mounted, also they are not damaged;

p) all poles are properly grouted/insulated so as to avoid bending of pole towards tension; and

q) steel poles, if used is properly earthed.

9.2.2.4 *Lighting and convenience power circuits*

For the lighting and convenience power circuits, it shall be checked whether:

a) wooden boxes are avoided;

b) panels are provided for mounting the lighting boards and switch controls, etc;

c) neutral links are provided in double pole switch-fuses which are used for lighting control and no protective device (such as MCB, MCCB, fuses, RCCB/RCD, etc) is provided in the neutral;

d) the plug points (6 A) in the lighting circuit are all of 3/5-pin type, the third pin being properly earthed;

e) the plug points (16 A) in the lighting circuit are all of 3/6-pin type, the third pin being properly earthed;

f) tamper-proof interlocked switch socket and plug are used for locations easily accessible;

g) wiring for lighting is taken in surface or recessed conduit and conduit properly earthed, or alternatively, armoured cable wiring is used in factories;

h) a separate earth wire is run in the lighting installation to provide earthing for plug points, fixtures and equipment;

j) proper connectors and junction boxes are used wherever joints are to be made in conductors or cross-over of conductors takes place;

k) clear and permanent identification marks are painted in all distribution boards, switchboards, sub-main boards and switches as necessary;

m) the polarity has been checked and all protective devices (such as MCB, MCCB, fuses, RCCB/RCD, etc) and single pole switches are connected on the phase conductor only and wiring is correctly connected to socket-outlets;

n) spare knockouts are provided in distribution boards and switch fuses are blocked;

p) the ends of conduits enclosing the wiring leads are provided with ebonite or other suitable bushes;

q) the fittings and fixtures used for outdoor use are all of weather-proof construction and of suitable IP and IK rating and similarly, fixtures, fittings and switchgears used in the hazardous area, are of flame-proof application;

r) proper terminal connectors are used for termination of wires (conductors and earth leads) and all strands are inserted in the terminals;

s) flat ended screws are used for fixing conductor to the accessories;

t) as desirable, flat washers backed up by spring washers are used for making end connections; and

u) all metallic parts of installation, such as conduits, distribution boards, metal boxes, etc, have been properly earthed.

9.3 Testing of Installation

9.3.1 *General*

After inspection, the tests as indicated in **9.3.2** shall be carried out, before an installation or an addition to the existing installation is put into service. Any testing of the electrical installation in an already existing installation shall commence after obtaining permit to work from the Engineer-in-Charge and after ensuring the safety provisions.

Testing of the installations will cover the testing of equipment, connections, cables, switchgear, protective devices, circuit breakers and the associated relays, measuring instruments and earthing. Periodicity of testing should not exceed six months. More frequent testing may be prescribed for complex installations and installations feeding sensitive loads. Due date of next test cycle should be displayed on the equipment.

The tests as detailed in **4.3** under Part 1 'General and common aspects, Section 17 Erection and pre-commissioning — Testing of installations' of good practice [D-2(1)] shall be carried out before energizing the installation and shall be recorded in the proforma attached under Annex E.

9.3.2 *Testing*

9.3.2.1 *Switchboards*

HV and LV switchboards shall be tested in the manner indicated below:

a) All high voltage switchboards shall be tested for insulation (phase to phase, phase to earth and body to earth);

b) In case of oil type switchboards, dielectric strength of oil shall also be tested;

c) All earth connections shall be checked for continuity;

d) The operation of the protective devices shall be tested by means of secondary or primary injection tests;

e) The operation of the breakers shall be tested from all control stations;

f) Indication/signalling lamps shall be checked for proper working;

g) The operation of the breakers shall be tested for all interlocks;

h) The closing and opening timings of the breakers shall be tested wherever required for auto-transfer schemes;

j) Contact resistance of main and isolator contacts shall be measured; and

k) The specific gravity and the voltage of the control battery shall be measured.

9.3.2.2 *Transformers*

Transformers shall be tested in the manner indicated below:

a) All commissioning tests shall be in accordance with good practice [D-2(16)]; and

b) Insulation resistance on HV and LV windings shall be measured at the end of 1 min, as also at the end of 10 min of measuring the polarization index. The absolute value of insulation resistance should not be the sole criterion for determining the state of dryness of the insulation. Polarization index values should form the basis for determining the state of dryness of insulation. For any class of insulation, the polarization index should be greater than 1.5. In case of oil type transformers, the dielectric strength shall be tested.

9.3.2.3 *Cables*

Cable installations shall be checked as given below:

a) It shall be ensured that the cables conform to the relevant Indian Standards. Tests shall also be done in accordance with good practice [D-2(23)]. The insulation resistance before and after the tests shall be checked;

b) The insulation resistance between each conductor and against earth shall be measured. The insulation resistance varies with the type of insulation used and with the length of cable;

c) Physical examination of cables shall be carried out;

d) Cable terminations shall be checked; and

e) Continuity test shall be performed before charging the cable with current.

9.3.2.4 *Motors and other equipment*

The following tests shall be made on motor and other equipment.

The insulation resistance of each phase winding against the frame and between the windings shall be measured. Megger of 500 V or 1 000 V rating shall be used. Star points should be disconnected. Minimum acceptable value of the insulation resistance varies with the rated power and the rated voltage of the motor.

The following relation may serve as a reasonable guide:

$$R_i = \frac{20 \times E_n}{1\,000 + 2P}$$

where

R_i = insulation resistance in MΩ at 25 °C;

E_n = rated phase to phase voltage; and

P = rated power, in kW.

If the resistance is measured at a temperature different from 25 °C, the value shall be corrected to 25 °C.

The insulation resistance as measured at ambient temperature does not always give a reliable value, since moisture may have been absorbed during shipment and storage. When the temperature of such a motor is raised, the insulation resistance will initially drop considerably, even below the acceptable minimum. If any suspicion exists on this score, motor winding shall be dried out.

9.3.2.5 *Wiring installation*

The following tests shall be done:

a) The insulation resistance shall be measured by applying between earth and the whole system of conductor or any section thereof with all fuses in place and all switches closed, and except in earthed concentric wiring, all lamps in position or both poles of installation otherwise electrically connected together, a d.c. voltage of not less than twice the working voltage, provided that it does not exceed 500 V for low voltage circuits. Where the supply is derived from three-wire (a.c. or d.c.) or a poly-phase system, the neutral pole of which is connected to earth either direct or through added resistance, the working voltage shall be deemed to be that which is maintained between the outer or phase conductor and the neutral;

b) The insulation resistance in mega-ohm (MΩ) of an installation measured as in (a) shall be not less than 50 divided by the number of points on the circuit, provided that the whole installation need not be required to have an insulation resistance greater than 1 MΩ;

c) Control rheostats, heating and power appliances and electric signs, may, if desired, be disconnected from the circuit during the test, but in that event the insulation resistance between the case of framework, and all live parts of each rheostat, appliance and sign shall be not less than that specified in the relevant Indian Standard or where there is no such specification, shall be not less than 0.5 MΩ; and

d) The insulation resistance shall also be measured between all conductors connected to one pole or phase conductor of the supply and all the conductors connected to the middle wire or to the neutral on to the other pole of phase conductors of the supply. Such a test shall be made after removing all metallic connections between the two poles of the installation and in these circumstances the insulation resistance between conductors of the installation shall be not less than that specified in (b).

9.3.2.6 *Earthing*

The following tests shall be done for the earth electrodes (earthing):

a) The earth resistance of each electrode shall be measured;

b) Earth resistance of earthing grid shall be measured;

c) All electrodes shall be connected to the grid and the earth resistance of the entire earthing system shall be measured; and

d) After receipt of electrical supply, the fault loop impedance shall be measured to ensure that the value obtained is minimal and to comply with the provisions under the CEA Regulations No. 43 (*see* Annex B) and good practice [D-2(11)].

These tests shall preferably be done during the summer months.

9.3.2.7 *Lightning protection system* (*LPS*)

Lightning protection system (LPS) verification shall be done as per accepted standards [D-2(52)] including the details of calculation of risk assessment and the selection of lightning protection level. The objective of inspection of LPS shall include whether all components of LPS are in good condition and capable of performing their designed functions and there is no corrosion. Inspections shall include checking of embedded electrodes, earth resistance values for the earth termination system, conditions of connections, equipotential bonding and fixings. The complete LPS shall be tested by opening one of the test joints to ensure that the total LPS system does not have more than 10 Ω to the earth. In case, if the total resistance of LPS exceeds 10 Ω then additional down conductors should be planned from air terminations and mesh conductor system, based on rolling sphere/mesh/protection angle method, to the earth so that the overall resistance is brought down to below 10 Ω by uniformly placing the additional down conductors. The testing shall also comply with all provisions included in **4.4** of Part 1 ‘General and common aspects, Section 17 Erection and pre-commissioning — Testing of installations’, of good practice [D-2(1)] and IEC 62305-3 : 2024 ‘Protection against lightning — Part 3: Physical damage to structures and life hazard’.

9.4 Checklist for Installation

The testing and submission of reports of all electrical installations shall be done as detailed in the model form in Annex D of Part 1 ‘General and common aspects, Section 17 Erection and pre-commissioning — Testing of installations, of good practice [D-2(1)]. In addition, the checklist covering set of checks for installation, handing over and commissioning of typical equipment of a substation as given in Annex E is for general reference and use. For other allied installation, the proper checklist should be developed keeping in view the type of loads, quality of service, environmental conditions and operating requirements of redundancy and reliability.

9.5 Completion Certificate

On completion of an electrical installation (or an extension to an installation) a certificate shall be furnished by the contractor, counter-signed by the certified supervisor under whose direct supervision the installation was carried out. This certificate shall be in a prescribed form as required by the local electric supply authority. One such recommended form is given in Annex F. This is a general form giving the minimum basic requirements and the items in the form have to be augmented keeping in view the features of the particular equipment, system or installation and environmental conditions of its operation.

10 ALLIED/MISCELLANEOUS SERVICES

10.0 General

The allied and miscellaneous services covered under this are special type of services which may or may not be part of the main electrical installations of the building but are services which are used in the building and may sometimes use electrical supply to run the services. This also covers the photovoltaic and other rooftop generation system which will get integrated with the electrical supply system for the building. This clause also covers inverters, UPS and small portable generation system to meet certain emergency requirements. The chapter also covers broadly the provisions for EV charging, Data centres and multeystorey buildings beyond 24 storeys. This clause provides the requirements related to these services.

10.1 Telecommunication and Information and Communication Technology Services

10.1.1 *Telephone/Intercom Services*

10.1.1.1 House wiring of telephone subscribers in small buildings may be on the surface of walls or desirably, in a concealed manner through conduits. In large multi-storeyed buildings intended for commercial, business and office use as well as for residential purposes, wiring for telephone connections should be done in a concealed manner through conduits. The requirements of telecommunication facilities like telephone connections, private branch exchange and intercommunication facilities, should be planned well in advance so that suitable provisions are made in the building plan in such a way that the demand for telecommunication services in any part of the building at any floor are met at any time during the life of the building.

10.1.1.2 Layout arrangements, methods for internal block wiring and other requirements regarding provisions of space, etc may be decided depending on the number of phone outlets and other details in consultation with engineer/architect and user. *See also* Part D ‘Building Services, Section 6 Information and Communication Enabled Installations’ of this NBCS.

10.1.2 *Fibre to The Home* (*FTTH*) *Services*

Fibre to the home (FTTH) services provide high speed internet, television and phone directly to a home or business using fibre optic cables. These services provide significantly higher bandwidth, faster speeds and more reliable connections compared to traditional broadband with advanced features such as high-definition video streaming, online gaming, etc. Instead of copper wires, FTTH uses thin strands of glass or plastic fibre(s) which transmit data as light signals.

Installing FTTH network is straightforward fibre installation with some additional components like splitters, an optical network terminal (ONT) and associated hardware at the customer premises. For more details, reference may be made to Part D 'Building Services, Section 6 Information and Communication Enabled Installations' of this NBCS.

10.1.3 *Information and Communication Technology Services including Computer Networking*

See Part D 'Building Services, Section 6 Information and Communication Enabled Installations' of this NBCS.

10.2 Public Address System

See Part F 'Fire and Life Safety' of this NBCS.

10.3 Emergency and Standby Power Supply Systems

10.3.1 *General*

Use of electricity has grown tremendously and for various activities the dependency on electricity has increased to such an extent as to cause serious problems even with loss of electrical power for a very short time. As a result, a wide variety of alternate sources of electricity are being used in our built environment.

The different alternative sources of power are the uninterrupted power supply (UPS) system, inverter, diesel (CNG/LPG) generator sets, petrol/kerosene oil generator sets and bio-gas generator sets.

In addition to the above, there is a proliferation of power sources, such as solar photo-voltaic cells, wind generators, bio-mass and waste-based power plants, etc, primarily oriented towards reduction of the environmentally harmful CO_2 emissions.

These systems give electricity during the periods of the failure of the conventional grid based public energy system and keep our critical systems in continued operation. However, introduction of more than one source of electrical power results in safety related issues. For safety from electrical shock to human beings or livestock, the hazard is not just dependent on the main high-powered source such as the grid, but the hazard is the same from a low powered source also. Shock from a small 20 W inverter can be as dangerous as a shock from the grid with megawatts of power at the back. As such precautions from the angle of safety apply equally to all sources of power. Electric shock hazards are dependent on the system voltage and as such even a low capacity generator or an inverter (of capacity 100 VA) poses the same level of shock hazard as a multi-kilovolt ampere capacity generator and all protection provisions (such as earthing, earth leakage and overload breakers) shall be provided as done for a large capacity system.

Power devices contain fuel, batteries which are points of concentrated sources of energy constrained in a small place. Any unintended improper release of this bottled up energy can unleash devastating consequences, such as fire and as such care is required in location which houses any of these sources of electrical power and its associated components.

10.3.2 *Uninterrupted Power Supply* (*UPS*) *System*

UPS is an electrical device providing an interface between the mains power supply and sensitive loads (computer systems, instrumentation, etc). The UPS supplies sinusoidal a.c. power free of disturbances and within strict amplitude and frequency tolerances. It is generally made up of a rectifier/charger and an inverter together with a battery for backup power in the event of a mains failure with virtually no time lag.

In general UPS system shall be provided for sensitive electronic equipment like computers, printers, fire alarm panel, public address system equipment, access control panel, EPABX, etc, with the following provisions. In addition, provisions as given in good practice [D-2(1)] shall also be followed.

a) Isolation transformers may be provided for UPS systems to provide higher grade of power supply quality to the loads fed by the UPS.

b) UPS shall have dedicated neutral earth pits of IT system. This earth pit shall be interconnected with other earth pits below soil for equipotential bonding and comply with the provisions of good practice [D-2(11)].

c) Adequate rating of protective devices such as MCB, MCCB, fuses, RCD, etc shall be provided at both incoming and outgoing sides.

d) UPS room shall be provided with adequate ventilation and/or air conditioning as per requirement, to avoid thermal runaway.

e) For all 3 phase UPS, 4 pole circuit breaker (CB) shall be used and for all 1 phase UPS, double pole CB shall be used.

f) The system shall confirm to set of accepted standards [D-2(53)].

10.3.3 *Inverter*

In general inverter system shall be provided for house lighting, shop lighting, etc.

NOTE — While a UPS system is provided to maintain power supply without any break even in the event of a failure of the incoming power supply, an inverter system is provided where a short break is acceptable.

Inverter systems also have a battery bank to supply power during the failure of the main power supply and the battery charged through a rectifier. The following provisions shall apply to inverter systems:

a) Adequate rating of protective devices such as MCB, MCCB, fuses, RCD, etc, shall be provided at both incoming and outgoing sides;

b) Earthing shall be done in accordance with good practice [D-2(11)];

c) Adequate ventilation space shall be provided around the battery section of the inverter; and

d) Care shall be taken in circuit design to keep the connected load in such a manner that the demand at the time of mains failure is within the capability of the inverter.

NOTE — If the inverter fails to take over the load at the time of the mains failure, the purpose of providing the inverter and battery backup is defeated.

10.3.4 The following provisions shall apply to both inverter and UPS systems:

a) Circuits which are fed by the UPS or inverter systems should have suitable marking to ensure that a worker does not assume that the power is off, once the mains have been switched off from the DB for maintenance;

b) Electric shock hazards are dependent on the system voltage and as such even a low capacity generator or an inverter (of capacity 100 VA) poses the same level of shock hazard as a multi-kilovolt ampere capacity generator and all protection provisions (such as safety earthing, earth leakage and overload breakers) shall therefore be provided as done in case of a large capacity system;

c) UPS and inverter systems should be provided with protection to shut the output during abnormal conditions, such as overload or short circuit. Such systems may also have the choice of auto-restoration after a preset time delay and an ultimate lock-out after a number of restoration attempts. Warning should be displayed wherever the possibility of automatic restoration is possible;

d) Batteries that go with UPS and inverter systems are required to be placed in well-ventilated spaces as oxygen and hydrogen gasses are produced in the batteries, which unless ventilated, can cause explosive conditions; and

e) The flooring for the battery room should be with acid (or alkali as the case may be) resistant tiles or coating.

10.4 Building Management System (BMS)

10.4.1 *General*

Building management system (BMS) is a computer-based system for monitoring and managing the building's mechanical, electrical and electro-mechanical systems including electrical substation equipment, HVAC, lighting, energy management, lifts, escalators, fire safety, security systems car parking management, etc. By its usage, building operations are optimized, energy efficiency is enhanced besides ensuring performance of all systems, safety and improving occupant's comfort.

10.4.2 *Working*

BMS provides a central platform for effective monitoring and efficient management of various building services. It allows remote monitoring and control from a single desk/location.

Separate standalone monitoring and control system provided for each service like electrical sub-station equipment; solar power and renewable energy system; standby generation system; HVAC system for control of operation and monitoring of all equipment including comfort conditions like temperature, humidity and air quality; fire protection system combining fire detection and firefighting arrangements, public address system (evacuation system); security system consisting of access control, CCTV, security fencing, water management system; etc can all be further integrated with BMS for remote monitoring, control and management .

By using sensors, it collects data on various parameters of all systems including comfort conditions of individual rooms/areas such as temperature, humidity, air quality, energy consumption based on occupancy level and adjusts system settings automatically for optimization of performance and eliminating wastage of energy thereof. Additionally, it can also spot inconsistencies and can send alerts to maintenance engineers to address the problems promptly.

The software of BMS also includes various features of reporting and analytics for improving building performance and identification of improvement areas. By integrating it with other building systems a more comprehensive and efficient solution of building management can be attained.

10.4.3 *Compliance with Regulations and Standards*

Where mandated, the relevant energy efficiency and safety standards prescribed by the Bureau of Energy Efficiency (BEE), Part F ‘Fire and Life Safety’ of this NBCS and other relevant parts and sections of this NBCS should be complied with. It should also be capable of seamless integration and exchange of data with other systems and devices functioning within the building. Designed for optimal performance, this system should be protected against unauthorized access and cyber threats.

10.5 Security System

Security system may comprise an integrated closed circuit television system, access control system, perimeter protection systems, movement sensors, etc. These have a central control panel, which has a defined history storage capacity. This main control panel may be located where it can be manned suitably with provision for integration to the fire detection and alarm system when considered necessary.

These may be considered for high security areas or large crowded areas or complexes. High security areas may consider uncorded, high-resolution, black and white cameras in place of coloured cameras. These cameras may be accompanied or automatically controlled with movement sensors. Cameras may be linked to access controls so that proper recording of the movement at the points of access to high security areas is maintained.

Access control may be provided for entry to high security areas. The systems may have proximity card readers, magnetic readers, etc.

> NOTE — *See* relevant guidelines/best practices (Handbook on ‘Asset and Facility Management in Buildings’) for provisions relating to security system.

10.6 Car Parking Area

10.6.1 *Car Parking Management System*

Wherever car park management system is provided in multi-level parking or other parking lots with features of boom barriers, pay and display machines (manned or unmanned type) and parking guidance system (for displaying number of car spaces vacant on various floors, direction of entry and exit, etc), the electrical provisions for the same shall be adequately backed with UPS for protection of vehicle and for efficient car parking management.

10.6.2 *Emergency Lighting in Basement Car Parking*

Lighting at suitable points should be provided on the passageway of the cars so that the public in the area can safely move away from the passage in the event of power failure.

10.7 Electrical Vehicle Charging

10.7.1 *General*

Increased use of electric vehicles (EVs) here resulted in the need for providing adequate EV charging infra structure in the built environment. It is recommended to provide for EV charging infrastructure for 20 percent of the parking area of buildings. Provisions of charging infra structure should be adequately increased such that slow charging of vehicles in parked condition for long duration can be undertaken in parking area of residential, office, institutional and in about 40 percent of commercial parking areas. Further, considering the rising status of EV adoption, the initial proposal of 20 percent parking space allocation for EVs may be increased up to 30 percent, say by 2030.

10.7.2 *Charging Arrangement*

Standards for charging of electric vehicles presently restrict the charging arrangements to open area and upto first basement with provisions of necessary sprinkler arrangement for firefighting services and necessary water curtain/compartment for fire protection. The charging infrastructure in podium/above ground parking do not provide significant risk considering the availability of cross ventilation in most such parking arrangements. However, with increased demand for charging infrastructure, the use of other basement may have to be considered. The charging arrangement in parking should be segregated individually for two wheelers and for four wheelers.

Charging arrangement for cars (four wheelers), can be provided both in ground level and first basement having adequate ventilation. However, two wheelers need to be segregated from four wheelers in parking and charging arrangement; and should be restricted to only ground floor level with adequate ventilation and firefighting arrangement using water mist fire system. The use of water mist fire system having up to 85 percent reduced water required for fighting the fire makes it a better option for both cooling effect and controlling electric fire in electric vehicles. The parking facility for the two wheelers shall be so arranged that not more than two vehicles should be parked side by side for charging and a space of not less than 1 m should be kept between the vehicle groups. The charging infrastructure should be provided in groups of four outlet points with three pin socket-outlets of 10 A capacity with 30 mA RCD control for each socket-outlet with metering arrangement. The spacing of the charging outlet shall be at a distance of 4 m/5 m on the basis of the parking arrangement provided.

In residential complexes, charging of vehicles would be preferred while parked for the day. Accordingly, it will not be advisable to keep parking of electrical vehicles contiguous to/vicinity of the petrol/diesel/CNG gas based vehicles. Hence separate segregated parking lot is required to be created for EVs (four wheelers) preferably in ground level/first basement with compartmentalized and water sprinkler fire barrier arrangement (for the basement). Suitable fire alarm/fire detection and fire ventilation system shall also be provided. Building professionals can consider developing suitable independent tower arrangement (podium) for car parking of electrical vehicles among the residential/commercial tower blocks and the building plan approval authorities can consider for suitable exemptions from the permitted area for construction.

It is necessary to provide for at least 20 percent of the vehicles in a residential complex with electric charging using a slow charging arrangement, as per Government guidelines. Hence each charging point shall be provided with two numbers 15 kW single phase two wire and two numbers 15 kW three phase four wire outlets controlled by suitable MCCB and RCD of 30 mA capacity with suitable metering arrangement. Each outlet shall be controlled by appropriate RCD/RCBO with rated residual operating current not exceeding 30 mA and necessary metering arrangement. In case of covered parking (first basement/podium), each location shall be provided with two sets of charging points. Each charging point shall be provided with access to portable firefighting arrangement within 15 m. The charging arrangement will be initially permitted to first basement only with compartment/sprinkler based water curtain and normal ventilation requirement of 15 to 18 air changes per hour with gas monitoring system. No charging infrastructure or EV parking shall be provided in the last basement. EV charging is a critical application from the point of fire safety, it is essential that all cables used for feeding the

EV charging stations of both two wheelers and four wheelers shall be of copper conductors for sizes upto 50 mm^2 4 core cables to prevent overheating with adequate earthing connections. All terminals shall be crimped to prevent loose connections.

It is also necessary to provide in the open area of the residential complex slow and fast charging points for 5 percent of the number of flats subject to minimum of two points with independent meter reading so that in case the number of electric vehicles increase in the complex, the users can take advantage of the fast charging arrangement. The arrangement shall be with two numbers 15 kW single phase two wire, 15 kW three phase four wire and 30 kW four wire outlets each controlled by MCCB of appropriate capacity, RCD of 30 mA capacity and metering arrangement.

10.7.3 As far as possible, EV charging arrangement shall be provided with independent transformer to ensure that harmonics created during EV charging do not interfere with power supply to other system and also to maintain other electrical parameters. A separate transformer is recommended for EV charging points where the total connected load exceeds 100 kW. It shall be ensured that EV charging is not fed from diesel generator sets or gas generators or similar fuel based power generating systems.

In case of hospitals, commercial complexes and big residential complexes, necessary public charging infrastructure shall be provided with 15 kW/30 kW/60 kW charging points duly controlled by appropriate capacity RCD/RCBO having rated residual current of 30 mA, necessary metering arrangement for each point with fast charger provisions. Spaces for EVs to be provided with charging facility for at least 20 percent of total vehicles. However, in the first basement, charging points shall be of capacity less 15 kW only.

All charging points, cabling, etc shall comply with accepted standards [D-2(54)] and good practice [D-2(1)] and the *CEA* (*Measures Relating to Electric Supply and Safety*) *Regulations*, 2023, with special reference to Regulation No. 123, 124, 125, 126, 127 and 128 (*see* Annex B).

10.7.4 *Battery Swapping System*

Battery swapping systems provide quick, safe and reliable swapping of the swappable battery system (SBS) of electric vehicles preferably two wheelers. The batteries will be loaded in a battery swap station (BSS). The SBS are stored in a battery rack in the BSS. The battery swapping is carried out by means of appropriate manipulators. EV battery swap system consists of:

a) battery swap station (BSS);

b) supporting systems;

c) swappable battery system (SBS); and

d) power supply system.

See accepted standard [D-2(55)].

Battery swap system shall be permitted only on ground floor (or on above ground floors) or outside the building line including battery storage zone and battery charging zone.

10.7.5 *Charging Infrastructure for Electric Buses*

Each electric bus depot shall be equipped with a minimum of two direct current (d.c.) fast chargers, each rated at not less than 240 kW, conforming to power level 3 or level 4. Chargers shall comply with the following Indian Standards:

a) d.c. charging protocol for heavy-duty vehicles — as per accepted standards [D-2(56)].

b) High-power d.c. charging systems — as per accepted standards [D-2(57)].

c) EV-EVSE communication protocol (power line communication) — as per accepted standards [D-2(58)].

d) Connector and plug interface for M3 category vehicles — as per accepted standards [D-2(59)].

All installations shall conform to applicable safety norms as per the CEA Regulations and relevant Indian Standards.

10.7.6 *Safety Requirements for Residential Charging of Electric Vehicles*

10.7.6.1 *Scope*

This clause specifies safety requirements for the installation and use of electric vehicle (EV) charging systems in residential premises.

10.7.6.2 *General safety provisions*

a) Only devices listed by a qualified testing laboratory shall be used.

b) Manufacturer's instructions shall be read and complied with.

c) Chargers and cords shall be inspected for damage prior to use; damaged components shall not be used.

d) Use of extension cords with EV chargers shall not be permitted.

e) Charging equipment shall be installed in locations that are:

    1) away from high-traffic areas; and

    2) free from proximity to combustible materials.

f) Charging accessories shall be stored out of reach of children and animals when not in use.

g) Charging station outlets shall be covered to prevent ingress of water.

h) Prior to initiating home charging, a qualified electrician shall:

    1) assess the capacity of the existing electrical system; and

    2) install a dedicated circuit for the charging device.

10.7.6.3 *Precautionary measures*

Warning signs shall be prominently displayed to ensure the safety of maintenance personnel. The signage shall include the following statements:

a) The vehicle is equipped with high-voltage batteries;

b) Battery maintenance shall be undertaken only by the manufacturer or authorized personnel; and

c) Orange-coloured high-voltage cables shall not be touched.

10.8 Solar Photovoltaic Power Generating System in Buildings

10.8.1 *General*

Solar energy, which is available in two forms, heat and light, is a renewable and inexhaustible natural resource and can supplement/augment the depleting fossil fuel resources. Greenhouse gases and pollutant emissions which result from fossil fuel generation can also be offset by solar photovoltaic power generation. Most parts of the country receive good solar radiation of 4 kWh/m^2 to 7 kWh/m^2 per day and almost 300 sunny days in a year making solar PV system one of the most preferred renewable energy sources in the country.

10.8.2 Solar PV power generating system consists of components and subsystems that are used to convert incident solar radiation directly into electrical energy. The energy converter (namely, solar photovoltaic cells which convert solar energy directly into d.c. electric power) does not have moving parts and has a comparatively long lifetime. Also, it can be used in decentralized/distributed mode.

10.8.3 *Rooftop Solar System*

The energy received from the sun is converted into electricity through photovoltaic cells and is called solar photovoltaic electricity. This is done by solar photo-voltaic system consisting of solar PV panels containing group of solar cells which generate d.c. power and using inverter and other equipment of appropriate capacity, the d.c. power is converted into a.c. power. The complete system comprising of inverter, cables both d.c. as well as a.c., protection system, interconnections, etc, which together is known as balance of system. Thus, solar PV system consists of solar PV panel and balance of system. The basic unit of solar panel, that is, solar cells are semiconductors made of silicon. The PV cells are made using different technologies namely monocrystalline silicon, polycrystalline silicon, thin film, etc. The choice among them is based on efficiency, cost and application among other factors. (*See* Fig. 12).

The installation of rooftop solar PV system shall be in accordance with the Regulation No. 119 and 121 of *Central Electricity Authority* (*Measures Relating to Safety and Electric Supply*) *Regulations*, 2023 (*see* Annex B).

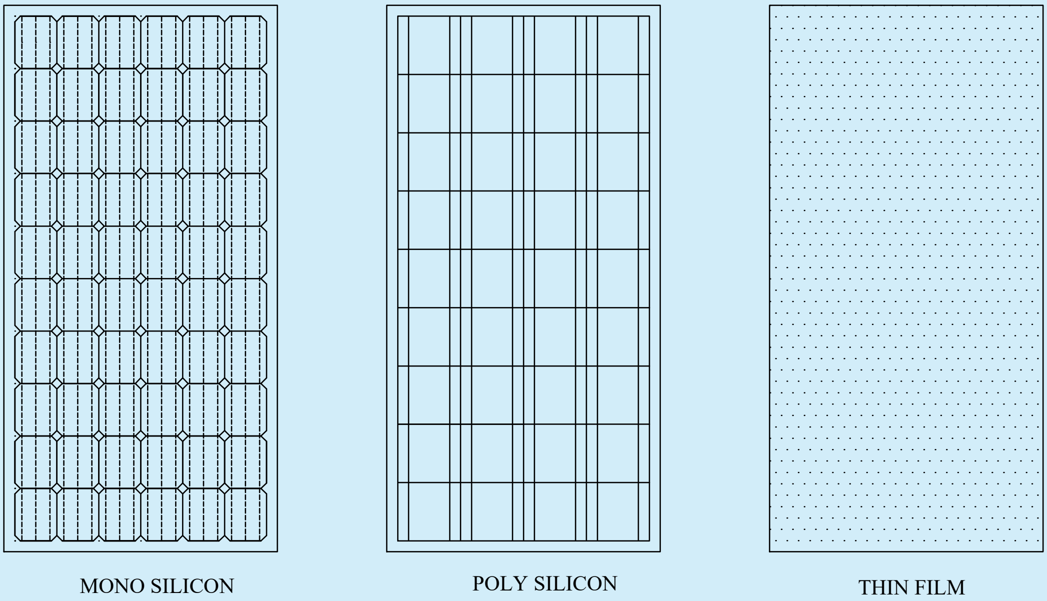

FIG. 12 MONO, POLY AND AMORPHOUS SILICON SOLAR CELL MODULE.

The solar PV systems used in buildings are of two types. Those installed on the rooftop are known as rooftop solar (RTS) system while solar PV system integrated with building facade is known as building integrated photovoltaic (BIPV) system.

10.8.3.1 *Solar PV components*

A brief description of all the major components are listed below:

Sl No. (1)	*Component* (2)	*Purpose* (3)	*Technical Requirements and Compliance Standard* (4)
i)	PV modules	To generate electricity utilizing the sunlight	Higher efficiency and lower cost meeting performance and safety standard as per accepted standards [D-2(60)] Modules to be connected in series and parallel to meet the inverter input requirement *See* accepted standard [D-2(61)].
ii)	Module mounting structure	To provide stability and rigidity to modules, to orient them towards the south direction at the appropriate latitude angle	Made of galvanized iron {*see* accepted standard [D-2(62)]} It should be capable of withstanding highest wind speed {*see* accepted standard [D-2(63)]}; and should have more than 25 years life.
iii)	d.c. and a.c. distribution boxes	To combine PV strings, to protect interconnections from corrosion, to house protective devices-fuses, surge protection devices, earth termination, breakers and isolators	GRP/FRP/powder coated aluminum enclosure. Should be weather and vermin proof, having required number of string entries and one cable exit having the required power rating and protection (IP 65) and as per relevant Indian Standard and good practice [D-2(1)]
iv)	Inverter	To convert d.c. power to a.c.	The inverter shall comply with all requirements as mandated in relevant Indian Standards, good practice [D-2(1)] and should produce grid quality power and be able to synchronize with it and having all mandated protection features of IP 54; accepted standards [D-2(64)]; and **5** of [D-2(65)] Interconnection and power quality shall be as per CEA/state regulation
v)	Cables (d.c. and a.c.)	To connect solar panels to inverter and enable safe flow of current	Copper cables with the required voltage rating and current carrying capacity shall be used for interconnection. The voltage drop should not exceed 2 percent. All d.c. cables shall be solar d.c. cable as per accepted standard [D-2(66)] and a.c. cables as per accepted standard [D-2(4)] and shall be copper conductor cable for sizes upto 50 mm^2.

Table (*Concluded*)

Sl No. (1)	*Component* (2)	*Purpose* (3)	*Technical Requirements and Compliance Standard* (4)
vi)	Earthing	To provide safe and alternate path for fault current and surge currents	Should be provided independently both on the d.c. and a.c. side of the circuit using copper/copper bonded steel down conductors {*see* good practice [D-2(11)]} and *CEA Safety Regulation*, 2023
vii)	Lightning protection system	To prevent damage caused by lightning surges	LPS should be provided as per accepted standard [D-2(52)]
viii)	Net meter	To measure net of energy exported to and imported from the grid	Installed by the DISCOM after calibration and sealing

10.8.3.2 *Solar PV systems classification*

There are mainly two types of PV systems namely grid tied system and the off-grid system.

In the grid tied system the building electrical loads are supported by both the solar power and the utility power. When solar power is insufficient to meet the load demand or is not available as during nights, power is drawn from the grid and when the generation is more, the excess is fed to the grid. A net meter is installed to measure the net of the energy drawn from and injected into the grid. The tariff for feeding excess power is typically fixed every year by the respective state regulatory commissions. A typical grid tie system is shown in Fig. 13.

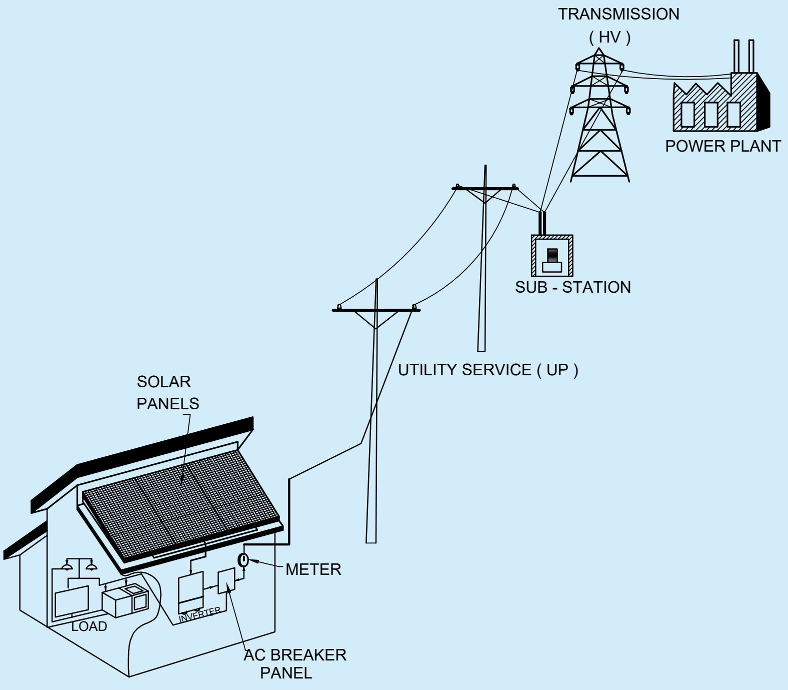

FIG. 13 GRID TIED SYSTEM

Off grid system is not connected to the grid and the loads are fully powered by solar. Since sunlight varies depending on the time of the day and the cloud levels and also since it is not available in the night, batteries are an inherent part of an off-grid system. These systems are used in places without electrical grid or by building owners desirous of being independent of grid connection (*see* Fig. 14).

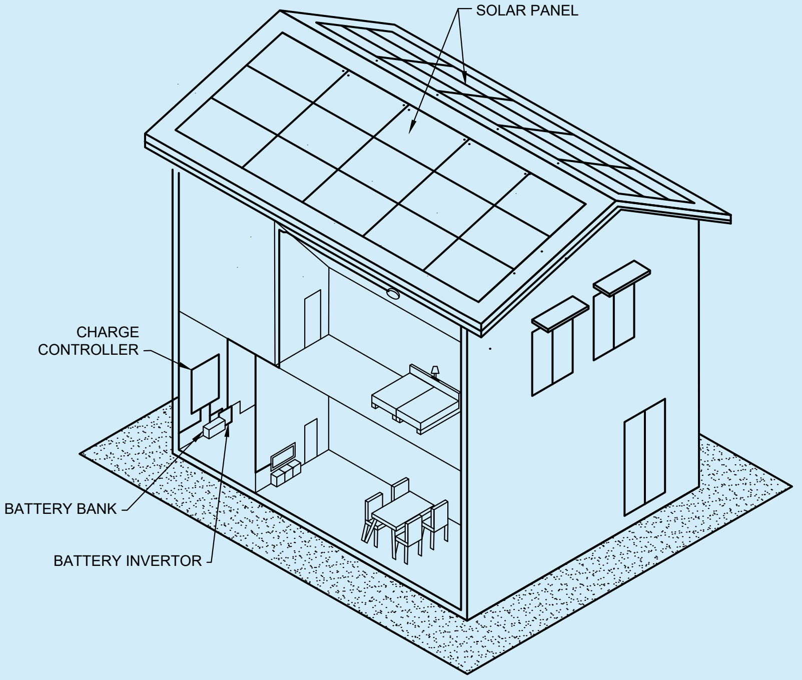

FIG. 14 AN OFF-GRID SYSTEM

10.8.3.3 *Protection system*

Since RTS is a power generating station on the topmost part of the building which is not in the view of occupants, it shall be protected against surge voltage, short circuit, lightning strike, earth fault, electrical fire, touch potential, shadow effect, etc by incorporating suitable protections into the system to avoid any mishap due to electrical fire. Special care should be taken to provide separate earth systems for d.c. power and a.c. power including interconnections and the earths will be interconnected at the earth level. The provisions for earthing and lightning protection shall be provided as per relevant Indian Standards and good practice [D-2(1)] including provision of necessary surge protection devices, where considered necessary.

10.8.3.4 *Solar PV system design*, *installation and maintenance*

Basic designing of the RTS depends upon the annual data relating to weather and solar insolation, shadow free area, generation potential, space required for other services, etc. For installation, all safety measures besides deployment of qualified personnel are required. Proper access to roof and distance between the row of solar panels is required for maintenance. System has to be maintained for guaranteed generation by regular cleaning of solar panels and inspection of the system for any abnormality from time to time.

10.8.3.5 *Regulations and standards relating to rooftop solar systems*

The system components shall comply with the relevant Indian Standards as amended up to date and work shall comply with the provisions of *Central Electricity Authority* (*Measures Related to Safety and Electric Supply*) *Regulations*, 2023 and good practice [D-2(1)]. Additionally, where mandated the use of solar d.c. cable as per accepted standard [D-2(67)] to prevent electrical fire on account of insulation failure due to exposure to UV radiations and weathering effect shall also be complied.

10.8.4 *Building Integrated Photovoltaic System* (*BIPV*)

BIPV system is an approach where conventional building components such as roofs and facades are replaced with multi-functional parts of a building envelope that integrate PV to generate electricity while still fulfilling their structural role.

BIPV refers to solar electric (photovoltaic) components that are integrated into the building envelope replacing the conventional building materials. Instead of being added on like traditional solar panels, BIPV models are designed to be part of building structure such as roofs, facades or skylights. This integration allows BIPV to serve both as a power generator and building material improving aesthetics and reducing reliance on conventional energy. Thus, there shall be regular meeting and consultation among the architects, engineers and builders to ensure seamless integration of BIPV into building design.

Building-integrated photovoltaics (BIPV) is an innovative technology that integrates seamlessly into a building envelope such as roofs, facades, windows and skylights. BIPV materials function both as conventional building elements as well as electricity producers (*see* Fig. 15).

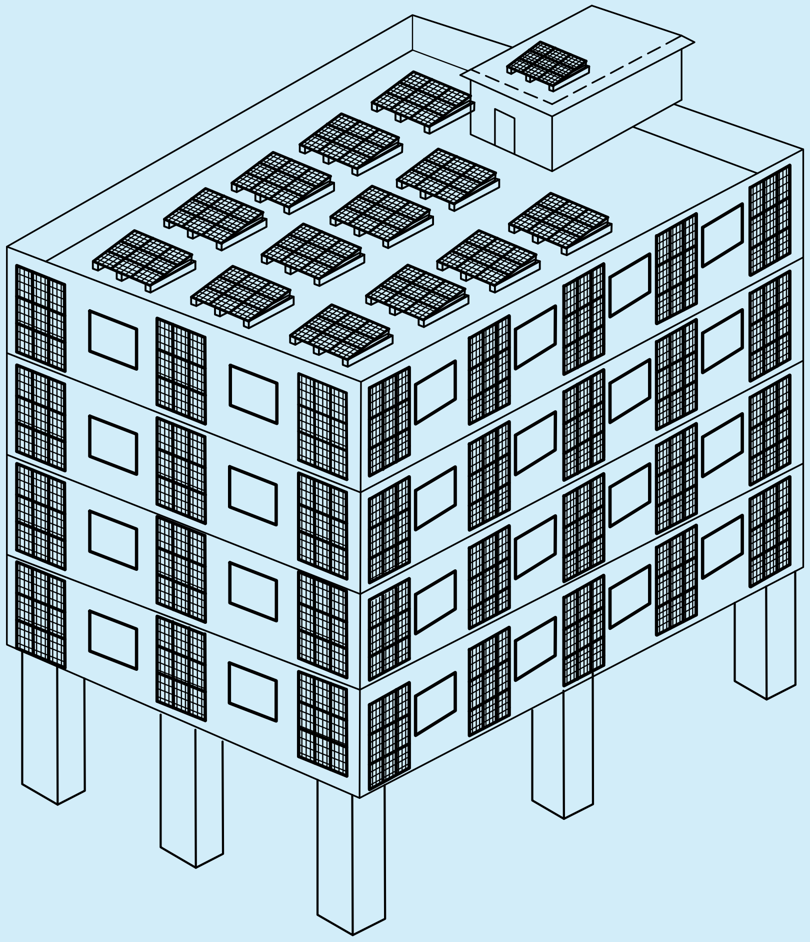

FIG. 15 BASIC STRUCTURE OF BIPV SYSTEM

10.8.4.1 *Design and planning of BIPV system*

a) *Building design integration* — Integration of BIPV technology into the building design is done, considering the factors like building orientation, shading, and structural integrity.

b) *Solar panel selection* — Solar panels are so selected to enable them to meet the structural and civil engineering requirements and are suitable for BIPV applications such as for facades, roof tiles, balustrades, window glazing/ atrium skylights.

c) *Energy generation* — The potential for energy generation is worked out based on system design optimization to achieve the maximum energy output for the components used.

10.8.4.2 *Installation and testing*

10.8.4.2.1 *Installation*

The installation of BIPV systems shall follow the manufacturer guidelines of the respective components and shall also comply with the relevant provisions of the structural requirements to ensure proper connectivity among the components. BIPV system design and installation should be optimized through BIM.

10.8.4.2.2 *Testing*

See accepted standards [D-2(67)].

a) *Performance testing* — After installation, the BIPV system shall be checked to ensure that the system generates power as envisaged in the planning stage and the energy produced shall be monitored for assessing the overall energy output and efficiency. Suitable solar power meter with data logger and performance monitoring software shall be used to monitor the performance of the BIPV system installed.

b) *Safety inspection* — Necessary earth test measurements, insulation resistance test, continuity test, measurement of voltage and current shall be measured using appropriate earth tester, insulation resistance tester and multi-meter to confirm that all connections have been made correctly and the electrical components function as planned in the planning stage.

c) *Electrical testing* — Confirm that electrical components function correctly and safely by performing insulation resistance test and continuity test and by measuring voltage and current, using a multimeter, insulation resistance tester and earth tester.

d) *Structural testing* — Necessary structural testing shall be carried out to ensure the BIPV system can withstand environmental stresses that may occur during the lifetime of the building and also withstand necessary sun, rain, wind, etc.

e) *Integration testing* — All systems of the building so installed may be integrated using integration software load testers and communication testing tools so that the complete building acts as a single envelope.

f) *Weatherproofing and sealing* — Necessary leakage deduction and sealant inspection shall be carried out as per weather proofing guidelines so that BIPV system is weatherproof and does not cause any leakage or damage to the building or to the structure as a whole.

10.8.4.3 *Safety and maintenance*

a) *Electrical safety* — Electrical safety shall be ensured by following relevant good practices and accepted standards.

b) *Fire safety* — Fire safety shall be ensured by using fire-resistant materials and following the good practices.

c) *Maintenance* — The BIPV system shall be inspected at least once in a month to ensure optimal performance and timely maintenance including replacement of damaged components if any without any delay.

10.9 Solar Water Heating System

10.9.1 *General*

This system is provided on the buildings to harness the energy of sun for heating water for kitchen and bathroom. Small systems from 100 litres to 300 litres are suitable for residential use while beyond this capacity are used for canteens, guest houses, hotels and hospitals. Located on top of building, the water is heated to 60 °C to 80 °C. However, in cloudy weather, back up electrical heater is sometimes required. Since it is provided on top of the building, it is necessary to provide equipotential bonding with the down conductor of LPS system as per relevant regulation and standards.

10.9.2 *Working*

When the sun's rays fall on the collector panel, which is a component of solar water heating system, a black absorbing surface (absorber) inside the collector absorbs solar radiation and transfers the heat energy to water flowing through it. Heated water is collected in a tank which is insulated to prevent heat loss. Circulation of water from the tank through the collectors and back to the tank continues automatically due to thermo-siphon system (*see* Fig. 16).

Solar water heating system are broadly categorized as active systems having pumps and controls, and passive systems relying on natural convection. Further, based on the collector system, solar water heaters can be of two types, namely flat plate collector type and evacuated tube collector type. In the first type, solar radiation is absorbed by flat plate collectors which consist of an insulated outer metallic box covered on the top with glass sheet. A black absorbing surface (absorber) inside the flat plate collectors absorbs solar radiation and transfers the energy to water flowing through it.

In the second type, the collector is made of double layer borosilicate glass tubes evacuated for providing insulation. The outer wall of the inner tube is coated with selective absorbing material. This helps absorption of solar radiation and transfers the heat to the water which flows through the inner tube.

10.9.3 *Compliance with Regulations and Standards*

As mandated by the government solar collectors shall adhere to the accepted standard [D-2(68)]. Further, municipal corporation/local bodies may require solar water heating systems to be installed in new buildings in their territories including in renovated buildings.

Accepted standard [D-2(69)] caters to the requirements and components of flat plate collector type solar water heating system while accepted standard [D-2(70)] caters to glass evacuated tubes solar water heating system. Accepted standard [D-2(71)] caters to storage water tank for all glass evacuated tubes solar water heating systems.

10.10 Aviation Obstacle Lights

High-rise buildings and structures such as chimneys and towers are potential hazards to aircraft. The provision of aviation obstacle lights (AOL) on tall buildings/structures is intended to reduce hazards to aircraft by indicating their presence. AOLs, low, medium or high intensity obstacle lights, or a combination of such lights, shall be provided on buildings of different heights as per the requirements of Annex 14 to the 'Convention on International Civil Aviation, Volume I Aerodrome Design and Operations', International Civil Aviation Organization (ICAO). A general arrangement of AOLs in case of group of buildings is given in Fig. 17.

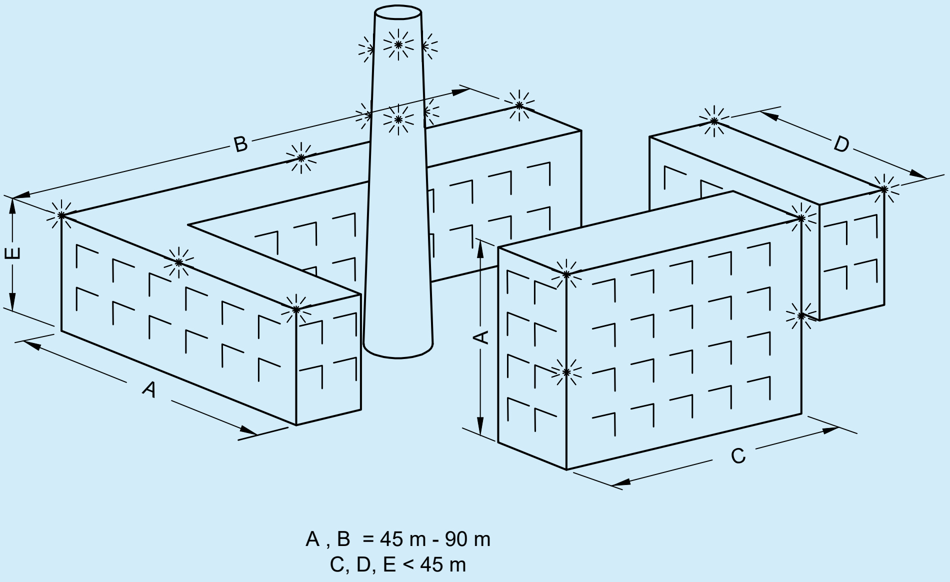

FIG. 17 TYPICAL ARRANGEMENT OF AVIATION OBSTACLE LIGHTS IN CASE OF GROUP OF BUILDINGS

10.11 Power/Electric Fence

10.11.1 *General*

Power/electric fence is provided in highly secured buildings to deter the intruders from climbing or sending a very low flying object, after proper risk assessment. It is provided on the boundary wall of the building and plays an important part in perimeter security by integrating with video surveillance software. This can also be used to protect the farms from the wild animals.

10.11.2 *Working*

This is a non-lethal fence consisting of wires carrying pulses of electric current and consists of an energizer producing regular current pulses. The supply lines conduct the pulses to the fence and takes back to the device from the earth stake. Wires should be good conductors and tied to the L-shaped posts securely over an insulator which separates the fence wire from the post and ensures that pulse current is not diverted to the ground. Height of the fence above the wall should be 1.5 m and spacing between wires shall be 100 mm. The distance between posts shall not be greater than 3 m and fence should be able to withstand the winds of 120 kmph when installed on boundary wall. A living object touching both wire and earth during pulse will get a shock and thus deter from entering the perimeter. The impact of shock depends upon the voltage, energy of the pulse, area of contact between the recipients, fence and ground, and the route of the current through the body. The intensity of shock can range from barely noticeable to uncomfortable or painful. It can also be solar powered. (*See* Fig. 18)

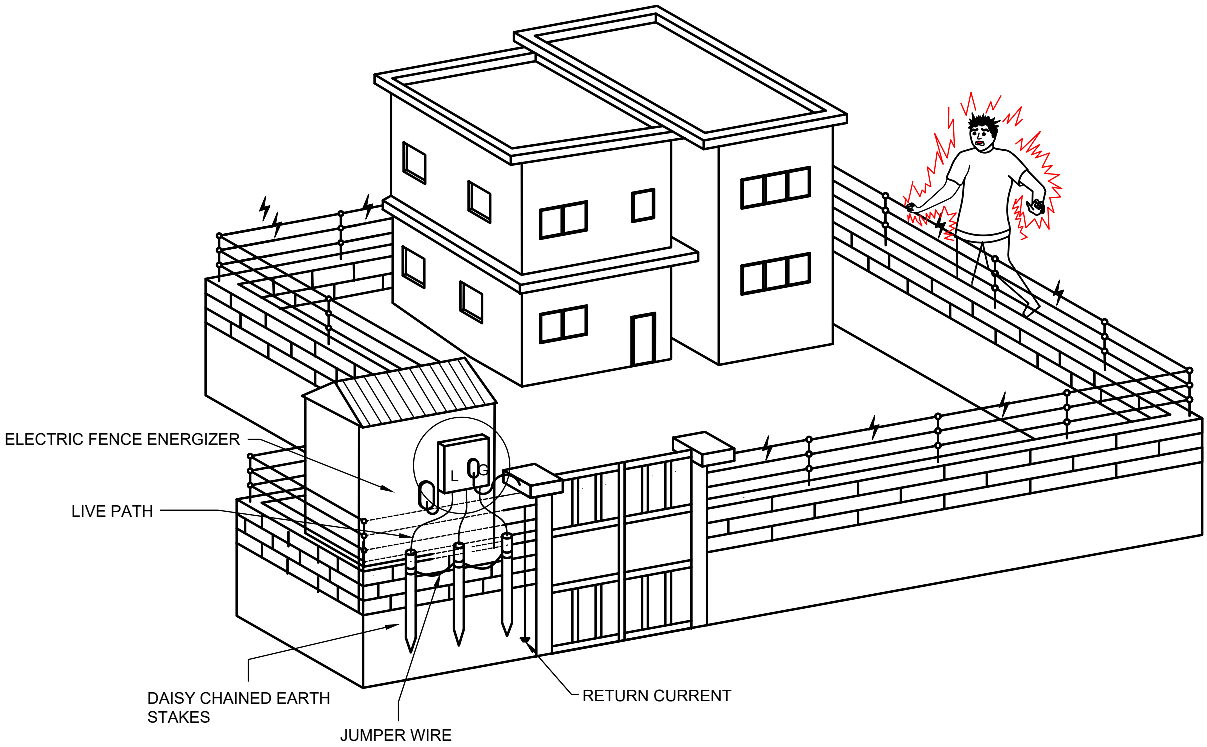

FIG. 18 POWER/ELECTRIC FENCE

10.11.3 *Compliance with Regulations and Standards*

It shall comply with specific safety and local regulatory standards. *See* accepted standard [D-2(72)] for safety and performance requirements. Prominent warning signs to alert people to the presence of the electric fence should also be displayed at regular intervals.

11 LIGHTNING PROTECTION OF BUILDINGS

11.1 General

Lightning flashes to, or nearby, structures (or lines connected to the structures) are hazardous to people, to the structures themselves, and to their contents and installations. Flashes of lightning discharges are of very high energy and can have devastating effects depending on the path of its discharge. Lightning strike is not predictable and is a random phenomenon both from the aspect of its occurrence and intensity or the energy discharge. There are no devices or methods capable of modifying the natural weather phenomena to the extent that they can prevent lightning discharges. Lightning protection measures therefore become essential. Lightning protection system (LPS) is the method of diversion of the lightning charges to the periphery of the building and to the ground so that the building, its occupants and sensitive equipment housed in the building, including connections from public systems to the building, are protected from the effects of lightning. The works carried out under this shall confirm to the relevant Indian Standards and the provisions of good practice [D-2(1)]. Brief details of the system are given hereunder.

NOTE — Reference is made to IEC 62305 (all parts) : 2024 instead of IS/IEC 62305 : 2010/11 since IEC 62305 : 2010/11 has been revised and is likely to be adopted by Bureau of Indian Standards shortly.

11.2 Steps for Deciding on Lightning Protection System

Lightning protection systems (LPS) are installed to avoid accidents, severe injuries and loss of life/deaths of humans and animals due to direct or indirect effects of lightning.

The following steps are to be followed to ensure protection from lightning in a building:

a) In order to utilize the building components such as reinforced cement concrete (RCC) columns and RCC foundation for embedded down conductor and earth termination system, the lightning protection system shall be considered and designed before starting the construction of the building;

b) Assess the need and level for lightning protection system based on risk and frequency of damage assessment as per IEC 62305-2 : 2024 'Protection against lightning — Part 2: Risk management' and the level of protection shall be identified along with coordinated SPDs to be connected to the power system and the telecommunication system;

c) Decide on the type of external LPS including usage of building components, corrosion problems, sizing of conductors and routing of conductors;

d) Calculate the separation distances, if isolated or electrically insulated LPS is used and find out the possibility of maintaining separation distance. Note that for high rise buildings, maintaining separation distance may not be practically possible. In such cases, alternate methods recommended in IEC 62305-3 : 2024 'Protection against lightning — Part 3: Physical damage to structures and life hazard' should be used. Equipotential bonding with the attached LPS shall be done at multiple levels and for exposed and extraneous metallic parts of the building;

e) Down conductors shall be placed to surround the building structure as uniformly as possible. Down conductors shall be installed vertically to provide the shortest and most direct path to the earth, and bends and joints should be avoided;

f) Decide on the type of earth termination system and the provisions for equipotential bonding at ground level. Type A earth termination (vertical or horizontal earth electrodes) is not efficient for large buildings. Lightning protection system without equipotential bonding (at ground level) to electrical installation is a safety hazard and shall be avoided;

g) In buildings where sensitive and large electronic systems are present such as datacentres, hospitals, telecommunication centres, etc, appropriate shielding measures shall be provided to mitigate the effects of electromagnetic disturbances; and

h) Measures to reduce touch and step potential outside the building, shall be adopted to ensure safety of the people.

While designing and execution of LPS, the following points shall be observed and implemented to prevent any unforeseen accidents due to lightning:

a) Where architectural or structural constraints exist, multiple down conductors shall not be routed collectively through vertical shafts or internal facades. In all such cases, appropriate separation distance between the conductors, continuous metallic bonding with accessibility for inspection and testing when required shall be ensured.

b) Equipotential bonding with the MET of the electrical installation and termination of SPDs shall be done.

c) Routing down conductors near metal installations such as facades, pipes, etc, without equipotential bonding should not be done.

11.3 Classification of Lightning Protection System

Class of LPS denotes the classification of an LPS according to the lightning protection level for which it is designed. Four classes of LPS I, II, III and IV are defined, based on the corresponding LPL I, II, III and IV. Each class of LPS is characterized by the rolling sphere radius, mesh size, protection angle, typical distance between down conductors, separation distance against dangerous sparking and minimum length of earth electrodes (IEC 62305-3 : 2024 'Protection against lightning — Part 3: Physical damage to structures and life hazard'). Acceptable method to determine the position of air termination system includes the protection angle method, rolling sphere method and the mesh method. The rolling sphere method is suitable for all classes. The protection angle method is suitable for simple shaped buildings but is subject to limits indicated in Table 3. The mesh method is suitable for plane surface protection.

11.4 Planning and Designing of Lightning Protection System

The lightning protection system (LPS) should be designed and installed by LPS designers or engineers experienced in LPS design. Planning, implementation and testing of an LPS encompasses a number of technical fields and demands for coordination by all parties involved with the construction and maintenance of the structure to ensure an efficient LPS.

It is essential to carry out the risk and frequency of damage assessment for a building based on IEC 62305-2 : 2024 'Protection against lightning — Part 2: Risk management' to decide the type of protection needed for lightning protection level and the level of coordinated SPDs required to be connected to the power line and telecommunication line. The lightning protection is divided into four levels (LPL I to IV) which helps in designing and implementing protection measures for an economical implementation. LPL I provides the maximum protection, whereas, LPL IV provides the least protection. Table 3 gives the values for different type of LPS.

Table 3 Maximum Values of Rolling Sphere Radius, Mesh Size and Protection Angle Corresponding to the Class of LPS

(*Clauses* 11.3, 11.4 *and* 11.6.1.7)

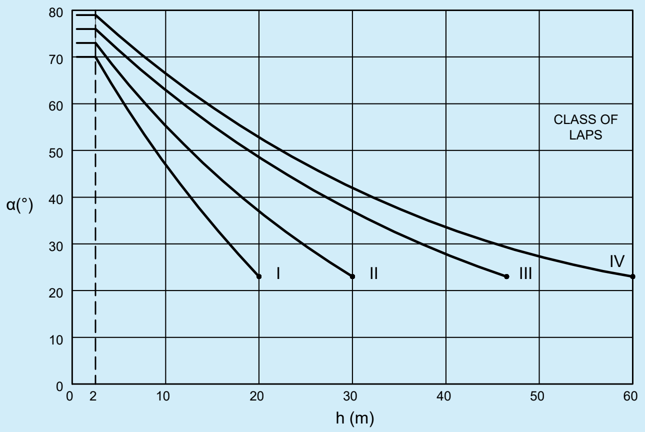
iii)	III	45	15 × 15	
iv)	IV	60	20 × 20	



NOTES

1 NOT APPLICABLE BEYOND THE VALUES MARKED WITH • ONLY ROLLING SPHERE AND MESH METHODS APPLY IN THESE CASES.

2 h IS THE HEIGHT OF AIR-TERMINATION ABOVE THE REFERENCE PLANE OF THE AREA TO BE PROTECTED.

3 THE ANGLE WILL NOT CHANGE FOR VALUES OF h BELOW 2 m.

FIG. 19 PROTECTION ANGLE CORRESPONDING TO THE CLASS OF LPS

Complete system for protection of structures against lightning, including their internal systems and contents, be installed to avoid damages to structures, accidents, severe injuries to humans due to direct or indirect lightning. Both protection measures should complement each other.

The management of the LPS should be efficient if the steps given in **11.2** are followed. Quality assurance measures are of great importance, in particular, for structures including extensive electrical and electronic installations. *See* accepted standards [D-2(73)] and [D-2(74)].

During the planning, various parties involved shall deliberate and agree on the following points which influence lightning protection system:

a) Decide whether or not the structure needs protection and if so, the special requirements have to be decided by making necessary calculations {*see* accepted standards [D-2(75)]};

b) Special attention shall be provided by architects and civil engineers on routing of down conductors, separation distance, usage of natural components and foundation earthing (*see also* Note);

c) Electrical separation and equipotential bonding shall be carefully analysed. Equipotential bonding of electrical services by SPD is also mandatory to complete lightning protection;

d) Ensure a close liaison between the architect/engineer, the builder, the lightning protection system engineer and the appropriate authorities throughout the design stages (*see* Note); and

e) Agree the procedures and define the period for testing and future maintenance {*see* accepted standard [D-2(76)]}.

NOTE — Modern buildings with electronic equipment need protection from radiated surges of lightning. To achieve this, structural steel of the building is also used as a part of lightning protection system {*see* accepted standard [D-2(73)]}. In such cases, lightning protection measures shall be included in the structural steel, particularly in column foundation.

11.5 Use of Building Components in Lightning Protection System

Conductive components installed not specifically for lightning protection system which can be used in addition to LPS or in some cases could provide the functions of one or more parts of LPS like natural air termination, natural down conductor, natural earth electrode are known as natural components of LPS {*see* accepted standard [D-2(76)]}.

Steel work within RCC structure is considered to be electrically continuous provided that major interconnections of vertical and horizontal bars are welded or otherwise securely connected. For new structures the connections between the RCC elements in the columns of the building shall be easily achieved by the designer in cooperation with the builder and the civil engineer by providing one additional smoothly finished copper/copper coated steel/stainless steel conductor/rod of diameter as indicated in Table 8. From foundation to the terrace continuously welded with suitable clamping/welding to all intervening horizontal bars (in case if single welded rod is not possible then necessary lapping between two rods shall be made as per IEC 62305-3 : 2024 ‘Protection against lightning — Part 3: Physical damage to structures and life hazard’). Thus, all external columns can act as down conductors for LPS and there will be no need for provision of separate external down conductors especially in architectural facia and glazed facia of the buildings. The overall electrical resistance of the reinforcement provided should not be greater than 0.2 Ω using test equipment suitable for this purpose. Suitable test joints shall be brought out from the structure at/near ground level for test purposes.

Interconnected reinforcement steel in concrete foundation buried directly in ground can be used as earth electrode. Special care shall be taken at the termination to prevent mechanical splitting of the concrete. Normally, a concrete raft foundation or pile foundation with pile caps of a building, provides reinforcement rods of not less than 25 mm having interconnected reinforcement steel duly clamped/welded, will provide a proper earth electrode and in closed loop formation. This will give a very good earth resistance for the down conductors and the overall value shall be measured to be less than earth resistance achieved normally.

The additional reinforcement provided for LPS shall be connected through welding to the foundation reinforcement and also with the roof conductors connecting the air termination through welding and suitably epoxy painted to prevent rusting. Thus, the LPS for the building shall become homogeneous after provision of air termination at the roof level based on rolling sphere/mesh system by interconnecting the top of the reinforcement from the columns with the terrace conductors (*see* Fig. 20).

Use of building components namely the cement concrete foundation and the columns, reduces not only the work of providing down conductors and earthing sets for the LPS and the cost thereof but also saves the difficulties of placing down conductors of LPS in respect of architectural facia of modern buildings. Also, test joints are not required for these cases {*see* **5.3.6** of accepted standard [D-2(73)]}.

NOTE — When incorporating a structure's natural components, such as rebar within the concrete foundation, specialized mechanical couplers or clamps {*see* accepted standard [D-2(77)]} may be specified during design to create secure equipotential bonding as per IEC 62305-3 : 2024 'Protection against lightning — Part 3: Physical damage to structures and life hazard'.

FIG. 20 CONSTRUCTION OF EXTERNAL LPS ON A STRUCTURE OF STEEL-REINFORCED CONCRETE USING THE REINFORCEMENT OF THE OUTER WALLS AS NATURAL COMPONENTS

11.6 Components of Lightning Protection System (LPS)

The main and most effective measure for protection of structures against physical damage is considered to be the lightning protection system (LPS). It usually consists of both external and internal lightning protection systems.

An external LPS which consists of air-termination system, down-conductor system and earthing system {*see* accepted standard [D-2(73)]} is intended to:

a) intercept a lightning flash to the structure (with an air-termination system);

b) conduct the lightning current safely towards earth (using a down-conductor system); and

c) disperse the lightning current into the earth (using an earth-termination system).

An internal LPS comprises equipotential bonding or a separation distance (and hence electrical insulation) between the external LPS components and other electrically conducting elements internal to the structure.

Both external and internal protection systems should complement each other.

Access to the ground and the proper use of foundation steelwork for the purpose of forming an effective earth-termination may well be impossible once construction work on a site has commenced. Therefore, soil resistivity and the nature of the earth electrode should be considered at the earliest possible preferably during the design stage of a project. This information is fundamental to the design of an earth-termination system and may influence the foundation design work for the structure.

Regular consultation between LPS designers and installers, architects/civil engineer and builders is essential in order to achieve the best result at minimum cost. If lightning protection is to be added to an existing structure, every effort should be made to ensure that it conforms to the principles of this NBCS. The design of the type and location of an LPS should take into account the features of the existing structure.

11.6.1 *Air-Termination System*

Air-termination system is a part of an external LPS using metallic elements such as rods, mesh conductors or catenary wires intended to intercept lightning flashes. The probability of penetration by a lightning current on a structure is considerably decreased by the presence of a properly designed air-termination system. Air-termination systems can be composed of any combination of the following elements:

a) vertical rods (offers certain angle of protection);

b) catenary wires; and

c) meshed/grid conductors.

Franklin rod (conventional) type of air-termination system shall be positioned in accordance with **11.6.1.1**. The individual air-terminations rods should be connected together at roof level to ensure current division. Radioactive air-terminals shall not be allowed. Any other kind of air-terminal like dissipation system/ESE air-terminal/CSE air-terminal or any other air terminal not approved by IEC 62305-3 : 2024 'Protection against lightning — Part 3: Physical damage to structures and life hazard' shall not be acceptable.

11.6.1.1 *Positioning*

Air-termination components installed on a structure shall be located at corners, exposed points and edges (especially on the upper level of any facades) in accordance with one or more of the following methods {*see also* Fig. 21 to Fig. 25 in conjunction with good practice [D-2(11)]}:

FIG. 25 DESIGN OF AN LPS AIR-TERMINATION ACCORDING TO THE PROTECTION ANGLE METHOD, MESH METHOD AND GENERAL ARRANGEMENT OF AIR-TERMINATION ELEMENTS

11.6.1.2 Roof mounted electrical/electronic equipment (for example, chillers, antennas, cameras and bill boards) need vertical air-termination to avoid direct strike. Power and data connection to these equipment should have proper SPDs (*see* 11.7.4) to avoid failures. Overhead cables such as cable TV lines from one building to the other should be avoided.

11.6.1.3 Unearthed metallic roofs should be avoided. Metallic roofs shall be connected either to steel reinforcement or to other earthed steel parts of the building satisfying the requirements of number of down-conductors (*see* 11.6.2).

11.6.1.4 *Structures of height less than* 60 m *and more than* 60 m

Lateral impacts of flashes to the side of tall structures are considered as negligible for structures up to 60 m in height measured from ground level. However, elements significantly protruding the facade can be endangered (for example, balconies, cameras, antennas).

On structures taller than 60 m, flashes to the side can occur, especially to protruding parts and to corners and edges of facades.

All external metal parts that have a conductive connection with internal metal parts separated by a distance $d > s$ from a down conductor (or air terminations) should not be connected to the down conductor so as to keep any unnecessary partial lightning currents out of the structure.

If this is not possible, the metal part should be directly bonded to the LPS. The possibility of the occurrence of partial lightning current into the structure should be considered.

NOTE — In general, the risk due to these flashes is low because only a few per cent of all flashes to tall structures will be to the side and their parameters are significantly lower than those of flashes to the top of structures. However, electrical and electronic equipment on walls outside structures can be destroyed even by lightning flashes with low current peak values.

An air-termination system shall be installed to protect significant protrusions (such as balconies, viewing platforms) on vertical surfaces on the upper part of tall structures (that is, typically the topmost 20 percent of the height of the structure), as well as the equipment installed on them (*see* Annex D of IEC 62305-3 : 2024 'Protection against lightning — Part 3: Physical damage to structures and life hazard'). For parts of the upper 20 percent that do not exceed 60 m above ground level, protection of the vertical surface is optional.

NOTE — Elements protruding through the facade of structures up to 60 m in height are rarely endangered.

11.6.1.5 *Roof top solar PV and water heaters on Buildings*

Vertical air-terminals are required for protecting roof mounted installations such as solar PV, water heaters, chillers as well as water tanks. Vertical air-terminals need to be connected to the air-termination mesh/down-conductors. Metal support structure of these installations shall be bonded to the air-termination mesh/down-conductors. Class I/Class II surge protection devices (SPDs) (*see* **11.7.4**) should be installed in the electrical lines to protect the installations inside the building (typically d.c. SPD for solar PV output at inverter or junction box level and a.c. SPD for inverter output and mains input). The roof top PV system or 230 V a.c. water heaters or any other equipment should not pose any safety risk related to lightning protection and protection of overall building may be reviewed by the expert after installation of roof top PV system. Necessary measures may then be required to complete the lightning protection arrangement.

Vertical air-terminals for PV modules based on LPL III/IV connected directly to the frame shall protect against direct lightning impact in solar PV power plant. A design according to rolling sphere method should be done for zone of protection (for example, 1 m rod at 0.5 m height from panel at four corners provides protection to approximately 12 m × 9 m area). Maximum height of the air-termination rod above the panel should be calculated considering the falling of shadow or umbra region of shadow not falling on any PV module. To reduce step potential, structures should be interconnected with underground earth mats/isolating spark gaps, wherever necessary (*see* Fig. 26 and Fig. 27).

FIG. 27 TYPICAL ARRANGEMENT OF EARTHING AND SURGE PROTECTION DEVICES IN SOLAR PV INSTALLATION

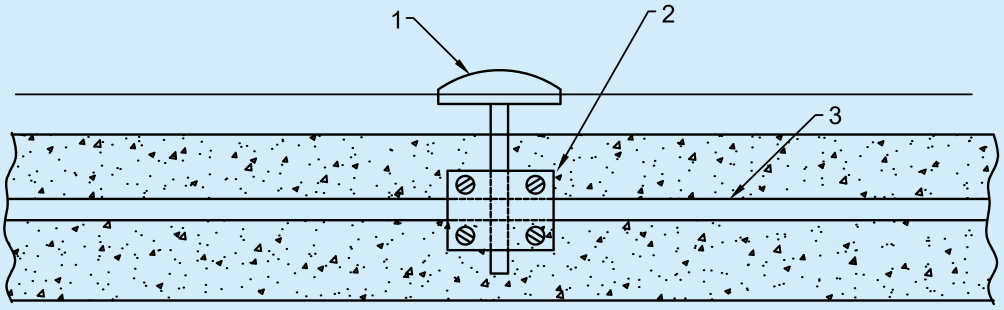
11.6.1.6 *Buildings with roof top telecom towers*

The metallic tower itself will act as air-termination. Antennas mounted above these towers need air-terminals connected to the main structure. The main structure shall be connected to the air-termination conductors for the balance of the building, if available. Two separate down-conductors with a size of minimum 150 mm^2 should be used in addition to regular down-conductors to make the bonding between tower and ring earthing. In order to avoid uncontrolled flash overs and also to protect equipment, which may be mounted on the tower itself, special cable with increased dielectric strength as down-conductor should be used in order to avoid separation distance. The area of cross section will be significantly lower than 50 mm^2 but not less than 28 mm^2, which is sufficient enough to discharge the lightning current where mechanical strength is not an essential requirement.

Every power, coaxial, data and other metallic lines connected between the telecom installation and the other parts of the building shall be protected with suitable SPD. It should be ensured that SPDs during their operation do not impede fire safety.

11.6.1.7 *Lightning protection for multi-storeyed car park roofs/helipads*

Air-termination studs (*see* Fig. 28) may be used for lightning protection for multi-storeyed car park roofs/helipads. Air-termination studs used can be connected to the reinforcement steel of a concrete roof. In the case of roofs where a connection to the reinforcement cannot be made, the roof conductors can be laid in the seams of the carriageway slabs and air-termination studs can be located at the mesh joints. The mesh width shall not exceed the value corresponding to the protection class given in Table 3. The persons and vehicles on this parking area are not protected against direct lightning.



KEY

1 AIR - TERMINATION STUD
2 STEEL CONDUCTOR CONNECTING TO SEVERAL BARS OF THE REINFORCEMENT STEEL
3 STEEL REINFORCEMENT TO CONCRETE

FIG. 28 TYPICAL AIR-TERMINATION STUDS USED ON CAR PARK ROOFS

11.6.2 *Down-conductor System*

Down-conductor system is a part of an external LPS intended to conduct lightning current from the air-termination system to the earth-termination system. The down conductor system shall confirm to 5.3 of accepted standard [D-2(73)]. In order to reduce the probability of damage due to lightning current flowing in the air-termination system, the down-conductors shall be arranged in such a way that from the point of strike to earth:

a) several parallel current paths exist;
b) the length of the current paths is kept to a minimum; and
c) equipotential bonding to conducting parts of the structure is performed.

11.6.2.1 Typical values of the distance between down-conductors are given in Table 4. These values can be used for horizontal ring conductors installed for a tall building more than 60 m height. The minimum number of down-conductors shall be 2 (diagonally opposite to each other) for building with an area less than 100 m^2.

Table 4 Minimum Distance between Down-Conductors

(*Clause* 11.6.2.1)

Sl No. (1)	Class of LPS (2)	Distance m (3)
i)	I	10
ii)	II	10
iii)	III	15
iv)	IV	20

11.6.2.2 Down-conductors shall be installed so that, as far as practicable, they form a direct continuation of the air-termination conductors. It shall be installed straight and vertical such that they provide the shortest and most direct path to earth. The formation of sharp bends and loops shall be avoided. Every down-conductor should be connected to a Type B ring/foundation earthing. Connection of down-conductor to a Type A earthing is allowed only in case of space constraints or existing buildings, where installation is difficult.

11.6.2.3 While routing the down-conductors, separation distance need to be calculated based on accepted standard [D-2(73)] and maintained from live parts/services.

11.6.2.4 Lateral connection of down-conductors at ground level and every 10 m to 20 m of height as a ring conductor, as per below table, is considered to be good practice. The installation of as many down-conductors as possible, at equal spacing around the perimeter interconnected by ring conductors, reduces the probability of dangerous sparking and facilitates the protection of internal installations {*see* accepted standard [D-2(73)]}. This condition is fulfilled in metal framework structures and in reinforced concrete structures in which the interconnected steel is electrically continuous.

11.6.2.5 Routing of down-conductors (insulated or uninsulated) through shafts with electrical and electronic system is not allowed. But routing of down conductors can be done through other service shafts by maintaining separation distance or with equipotential bonding of extraneous metal components.

11.6.2.6 Separation distance is the distance required between air-terminals/lightning down-conductor and any conductive/metallic/electrical/electronic part of a building to avoid uncontrolled flashover.

11.6.2.6.1 While calculating the separation distance, the parameter l (length, in m along the air-terminal and the down-conductor from the point where the separation distance is to be considered, to the nearest equipotential bonding point or earth termination system is not bonded to equipotential bonding point or the earth termination) is a major influencing factor. If the down conductors or the earth terminal system is not bonded to equipotential bonding system of the electrical installation in the building, the lightning protection system will be ineffective.

Cable with increased dielectric strength and tested for lightning current discharge may be used to avoid specific separation distance to live parts of the building {*see* accepted standard [D-2(73)]}.

11.6.2.7 The down-conductor shall be supported using suitable clamps or connectors or exothermic welding. The clamps or connectors or exothermic welding shall be tested for the lightning current as per selected LPL. Reference may be made to table given below and accepted standard [D-2(73)] for supporting details:

Sl No. (1)	*Arrangement* (2)	*Fixing Centres for Tape, Stranded and Soft Drawn Round Conductors* mm (3)	*Fixing Centres for Round Solid Conductors* mm (4)
i)	Horizontal conductors on horizontal surfaces	1 000	1 000
ii)	Horizontal conductors on vertical surfaces	500	1 000
iii)	Vertical conductors from the ground to 20 m	1 000	1 000
iv)	Vertical conductors from 20 m and thereafter	500	1 000

NOTES

1 This table does not apply to built-in type fixings, which may require special considerations.

2 Assessment of environmental conditions (that is, expected wind load) should be undertaken and fixing centres different from those recommended may be found to be necessary.

11.6.2.8 The wind speed shall be taken into account while mounting the air-termination and down-conductor system {*see* accepted standard [D-2(73)]}.

11.6.3 *Earth-termination System*

Earth-termination system is a part of an external LPS which is intended to conduct and disperse lightning current into the earth. When dealing with the dispersion of the lightning current (high frequency behaviour) into the ground, whilst minimizing any potentially dangerous overvoltages, the shape and dimensions of the earth-termination system are the important criteria. In general, a low earthing resistance (if possible lower than 10 Ω when measured at low frequency) is recommended. From the viewpoint of lightning protection, a single integrated structure earth-termination system is preferable and is suitable for all purposes (that is, lightning protection, power systems and telecommunication systems).

Type A earth-termination comprising of vertical/horizontal conductor or Type B earth-termination comprising of ring earthing/foundation earthing shall be used satisfying the requirements of this NBCS as well as accepted standard [D-2(73)]. In structures where only electrical systems are provided, a Type A earthing arrangement may be used, but a Type B earthing arrangement is preferable. In structures with electronic systems, a Type B earthing arrangement is recommended.

11.6.3.1 *Type A earthing*

Length of the earth electrode depends on the soil resistivity and class of LPS {*see* good practice [D-2(11)] for details and Table 5 for vertical earth electrode}.

Table 5 Minimum Length of Vertical Earth Electrode

(*Clauses* 11.6.3.1 *and* 11.6.3.2)

Sl No.	Class of LPS	Typical Length of Each Vertical Earth Electrode Based on Soil Resistivity m			
		Up to 500 Ω-m	1 000 Ω-m	2 000 Ω-m	3 000 Ω-m
(1)	(2)	(3)	(4)	(5)	(6)
i)	I	2.5	10	25	40
ii)	II	2.5	5	15	25
iii)	III	2.5	2.5	2.5	2.5
iv)	IV	2.5	2.5	2.5	2.5

11.6.3.2 *Type B earthing*

This type of arrangement comprises either a ring conductor external to the structure to be protected, in contact with the soil for at least 80 percent of its total length, or a foundation earth electrode. Such earth electrodes may also be meshed. For the ring earth electrode (or foundation earth electrode), the mean radius of the area enclosed by the ring earth electrode (or foundation earth electrode) shall be not less than the value of Type A earthing as given in Table 5 {*see* accepted standard [D-2(73)]}.

11.6.3.3 In industrial and commercial structures, the ring earth electrode around the structure or the ring earth electrode in the concrete at the perimeter of the foundation, should be integrated with a meshed network under and around the structure, having a mesh width of typically 5 m. This greatly improves the performance of the earth-termination system. If the basement's reinforced concrete floor forms a well-defined interconnected mesh and is connected to the earth-termination system, typically at every 5 m, the same will also be suitable {*see* accepted standard [D-2(73)]}.

11.6.3.4 Where large numbers of people frequently assemble in an area adjacent to the structure to be protected, further potential control for such areas should be provided. More ring earth electrodes should be installed at distances of approximately 3 m from the first and subsequent ring conductors. Ring electrodes further from the structure should be installed more deeply below the surface, that is, those at 4 m from the structure at a depth of 1 m, those at 7 m from the structure at a depth of 1.5 m and those at 10 m from the structure at a depth of 2 m. These ring earth electrodes should be connected to the first ring conductor by means of radial conductors.

11.6.3.5 For large buildings integrating structural steel as down-conductor and earth-termination, earth resistivity measurements are not required. Proper drawings should be made based on the actual installation and submitted to authorities if necessary {*see also* accepted standard [D-2(73)]}. However, provisions shall be provided for continuity resistance measurement.

11.6.3.6 Touch and step voltage safety measures outside structure shall be installed and maintained as per accepted standard [D-2(73)].

11.6.4 *Use of Natural Components*

11.6.4.1 Natural components installed not specifically for lightning protection system can be used in addition to LPS or in some cases could provide the functions of one or more parts of LPS, like natural air termination, natural down conductor, natural earth electrode. The use of building components such as columns and foundation have been explained in **11.5** separately, in order to give special attention for use of such systems in modern buildings.

11.6.4.2 *Bonding network*

A low impedance bonding network is needed to avoid dangerous potential differences between all equipment inside the building. Moreover, such a bonding network also reduces the magnetic field, thereby reduces the radiated surges inside the building and provides more protection for electrical electronic equipment {*see* accepted standard [D-2(74)]}.

This can be realized by a meshed bonding network integrating conductive parts of the structure, or parts of the internal systems, and by bonding metal parts or conductive services at the boundary of each lightning protection zone (LPZ) directly or by using suitable SPDs.

The bonding network can be arranged as a three-dimensional meshed structure with a typical mesh width of 5 m (*see* Fig. 29 and Fig. 30). This requires multiple interconnections of metal components in and on the structure (such as concrete reinforcement, elevator rails, cranes, metal roofs, metal facades, metal frames of windows and doors, metal floor frames, service pipes and cable trays). Bonding bars (for example, ring bonding bars, several bonding bars at different levels of the structure) and magnetic shields of the LPZ shall be integrated in the same way.

Conductive parts (for example, cabinets, enclosures, racks) and the protective earth conductor (PE) of the internal systems shall be connected to the bonding network {*see* accepted standard [D-2(74)]}.

11.6.5 *Materials and Dimensions*

Copper and aluminium are recommended for exposed areas on installations required to have a long life. Galvanized steel may be preferred for temporary installations such as exhibition centres. Although it is a common practice to use material in the form of strip for horizontal air-terminations, down-conductors and bonds, it is more convenient to use round material, particularly as it facilitates the making of bends in any plane. *See* Table 6, Table 7 and Table 8 for details for different materials and conditions of use, refer accepted standard [D-2(74)] for minimum dimension of materials used in LPS.

Table 6 LPS Materials and Conditions of Use[1]

(*Clause* 11.6.5)

---

[1] This table gives general guidance only. In special circumstances more careful corrosion immunity considerations are required.

[2] Galvanized steel may be corroded in clay soil or moist soil.

[3] Galvanized steel in concrete should not extend into the soil due to possible corrosion of the steel just outside the concrete.

[4] Galvanized steel in contact with reinforcement steel in concrete may, under certain circumstances, cause damage to the concrete.

[5] Stranded conductors are more vulnerable to corrosion than solid conductors. Stranded conductors are also vulnerable where they enter or exit earth/concrete positions. This is the reason why stranded galvanized steel is not recommended in earth.

[1] Mechanical and electrical characteristics as well as corrosion resistance properties shall meet the requirements as per accepted standard [D-2(78)].

[2] 50 mm^2 (8 mm diameter) may be reduced to 25 mm^2 in certain application where mechanical strength is not an essential requirement. Consideration should in this case, be given to reducing the space between fasteners.

[3] Applicable for air-termination rods and earth lead-in rods. For air-termination rods where mechanical stress such as wind loading is not critical, a 9.5 mm diameter, 1 m long rod may be used.

[4] If the thermal and mechanical considerations are important, then these values should be increased to 75 mm^2.

---

[1] Mechanical and electrical characteristics as well as corrosion resistance properties shall meet the requirements as per accepted standard [D-2(78)]

[2] In case of a Type B arrangement foundation earthing system, the earth electrode shall be correctly connected at least every 5 m with the reinforcement steel.

[3] Lattice plate constructed with a minimum total length of conductor of 4.8 m.

[4] Different profiles are permitted with a cross-section of 290 mm^2 and a minimum thickness of 3 mm, for example, cross profile.

[5] Shall be embedded in concrete for a minimum depth of 50 mm.

[6] 250 µm minimum radial copper coating, with 99.9 percent copper content.

[7] Chromium ≥ 16 percent, nickel ≥ 5 percent, molybdenum ≥ 2 percent, carbon ≤ 0.08 percent.

11.6.6 Protection measures against injury to living beings due to touch voltage and step voltage shall be provided in accordance with accepted standard [D-2(74)].

11.6.7 Inspection of the LPS shall be done as per IEC 62305-3 : 2024 'Protection against lightning — Part 3: Physical damage to structures and life hazard'.

11.7 Protection of Electrical/Electronic Systems within Structures

11.7.1 The internal LPS shall avoid the occurrence of dangerous sparking within the structure to be protected due to lightning current flowing in the external LPS or in other conductive parts of the structure. Dangerous sparking between different parts can be avoided by means of equipotential bonding or electrical insulation between the parts.

Permanent failure of electrical and electronic systems can be caused by the lightning electromagnetic impulse (LEMP) *via*:

a) conducted and induced surges transmitted to equipment *via* connecting wiring; and

b) the effects of radiated electromagnetic fields directly into equipment itself.

11.7.2 *Equipment Protection Principles*

11.7.2.1 For protection against the effects of radiated electromagnetic fields impinging directly onto the equipment, SPM consisting of spatial shields and/or shielded lines, combined with shielded equipment enclosures should be used.

11.7.2.2 For protection against the effects of conducted and induced surges being transmitted to the equipment *via* connection wiring, SPM consisting of a coordinated SPD system should be used. SPD to be used according to their installation position are as follows:

a) At the line entrance into the structure (at the boundary of LPZ 1, for example at the main distribution panel):
   1) SPD tested with I_{imp} (typical waveform 10/350, for example, SPD tested according to class I); and
   2) SPD tested with I_n (typical waveform 8/20, for example, SPD tested according to class II).

b) Close to the apparatus to be protected (at the boundary of LPZ 2 and higher, for example, at secondary distribution board, or at a socket outlet):
   1) SPD tested with I_n (typical waveform 8/20 for example, SPD tested according to class II); and
   2) SPD tested with a combination wave (typical waveform 8/20 for example, SPD tested according to class II).

11.7.3 *Equipotentialization of Services to LPS*

Equipotentialization is achieved by interconnecting the LPS with structural metal parts, metal installations having no electrical power connection, internal systems, external conductive parts and lines connected to the structure. *See* Fig. 31.

FIG. 31 EXAMPLE OF AN EQUIPOTENTIAL BONDING ARRANGEMENT

Interconnection can be done with bonding conductors, where the electrical continuity is not provided by natural bonding or by using surge protective devices (SPDs), where direct connections with bonding conductors is not feasible (for example, installation of SPDs for power, data, telecom lines, etc). It contains at least one non-linear component to ensure perfect equipotential bonding. All SPDs at the service entrance to an installation should be able to divert 10/350 µS impulse current depending upon selected level of protection. A three phase four wire system should be designed for 50 percent of the I_{imp} of selected LPS and single phase two wire system should be designed for 25 percent of the I_{imp} of selected LPS. The lightning current distribution for three phase four wire system is given in Fig. 32 {*see also* accepted standard [D-2(75)]}.

11.7.4 *Protection Measures with Surge Protection Devices* (*SPDs*)

11.7.4.1 Lightning surges frequently cause failure of electrical and electronic systems due to insulation breakdown or when overvoltages exceed the equipment's common mode insulation level. Power line protection is fundamental, however equal importance should be given to data, communication and instrumentation lines of the equipment that need protection. Equipment is protected if its rated impulse withstand voltage U_{W} at its terminals is greater than the surge overvoltage between the live conductors and earth. If not, an SPD shall be installed.

Implementing coordinated SPDs will provide protection against radiated surges for equipment {*see* accepted standard [D-2(74)]}. Shielding and routing of power and data lines, bonding of services and various lightning protection zones (LPZ) {*see* accepted standard [D-2(74)]} and earthing also plays a major role in protecting electrical and electronic equipment.

The SPDs are used to protect under specified conditions, electrical systems and equipment against various overvoltages and impulse currents such as lightning and switching surges. SPD shall be selected according to their environmental conditions and the acceptable failure rates of the equipment and the SPDs.

11.7.4.2 *Failure of SPDs*

Possibility of failure of any line to neutral or neutral to earth connected SPDs should not be ruled out, hence measures should be taken within the SPD for safe failure or withstand in worst conditions. SPD can fail in open or short modes. SPD should not create a fire hazard during failure. Safe failure mode is expected from the SPD.

11.7.4.3 *Status indicators*

Each SPD should have inbuilt health indicator so as to show if protection is available. SPD should be installed in a way that visual inspection is easily possible. Failed SPD shall be replaced.

11.7.4.4 SPDs for power line need to be installed according to the type of service such as TN, TT, IT, etc. In general, the SPDs connected as per connection diagram given in Fig. 33 (informative) is suitable for TT connections. Reference may be made to relevant Indian Standard for such installations.

33B SPDS ON THE SUPPLY SIDE OF RCD

FIG. 33 TYPICAL INSTALLATION OF SPDS IN TT SYSTEM

11.7.4.5 *Selection of SPDs*

SPD(s) need to be selected based on the place of installation as well the impulse voltage withstanding capacity of the equipment. I_{imp} and I_n, are test parameters used to categorize Class I and Class II SPD(s). They are related to the maximum values of discharge currents, which are expected to occur at the LPL probability level at the location of installation (LPZ) of the SPD in the system. I_n is associated with Class II tests and I_{imp} is associated with Class I tests.

11.7.4.5.1 If no risk analysis according to accepted standard [D-2(76)] has been carried out or if the current value of SPD cannot be established, Class I SPDs should be installed with an I_{imp} not less than 12.5 kA (10/350µS) for connection according to Fig. 33A or between L to N or PE. For connection according to Fig. 33B, I_{imp} shall not be less than 50 kA (10/350µS) between N and PE for three-phase systems and 25 kA (10/350 µS) between N and PE for single-phase systems. Otherwise, the currents shall be considered as per level of protection.

11.7.4.5.2 *Follow current extinguishing capability of the SPD*

Follow current is the peak current (rms value) supplied by the electrical power system and flowing through the SPD after a discharge current impulse. Follow current extinguishing capability and short circuit withstand capacity of SPD shall be as per accepted standard [D-2(74)].

11.7.4.5.3 Where Class II tested SPD {*see* accepted standard [D-2(76)]} are required at or near the origin of installation, the value of I_n shall be not less than 5 kA for connections according to Fig. 33A or between L to N or PE. For Class II tested SPDs connected between neutral and PE for connection in Fig. 33B, I_n shall not be less than 20 kA for three-phase systems and 10 kA for single-phase systems.

11.7.4.5.4 *Voltage protection level of SPD*

The voltage protection level of SPD is the maximum voltage to be expected at the SPD terminals due to an impulse stress with defined voltage steepness and an impulse stress with a discharge current with given amplitude and wave shape. The protection level of SPDs shall be selected in accordance with impulse withstand voltage category as per Table 9.

---

[1] *See* accepted standard [D-2(80)].

[2] The '/' mark indicates a four-wire three-phase distribution system. The lower value is the voltage line-to-neutral, while the higher value is the voltage line-to-line. Where only one value is indicated, it refers to three-wire, while the higher value is the voltage line-to-line. Where only one value is indicated, it refers to three-wire, three-phase systems and specifies the value line-to-line.

[3] Equipment with these rated impulse voltage can be used in installations in accordance with IEC 60364-4-44 'Low-voltage electrical installations — Part 4-44: Protection for safety — Protection against voltage disturbances and electromagnetic disturbances'.

[4] *See* **4.3.3.2.2** of accepted standard [D-2(80)].

11.7.4.5.5 The preferred values of voltage protection level of SPDs, U_p is given below (*see* accepted standard [D-2(81)]):

0.08 kV, 0.09 kV, 0.10 kV, 0.12 kV, 0.15 kV, 0.22 kV, 0.33 kV, 0.4 kV, 0.5 kV, 0.6 kV, 0.7 kV, 0.8 kV, 0.9 kV, 1.0 kV, 1.2 kV, 1.5 kV, 1.8 kV, 2.0 kV, 2.5 kV, 3.0 kV, 4.0 kV, 5.0 kV, 6.0 kV, 8.0 kV and 10 kV

Hence, for protecting a 240 V/415 V connected equipment, selecting a $U_p \leq 1.5$ kV will be a safer choice. The U_p may be tested and certified by a third party as per the laid down test procedures. *See* Fig. 34 on connection diagram for SPD.

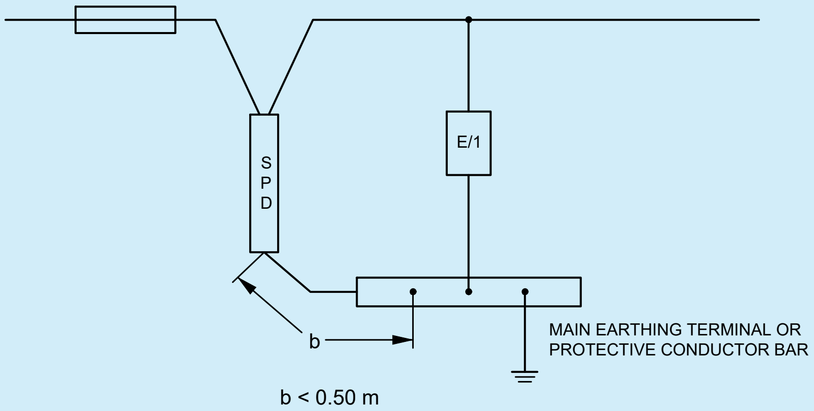

FIG. 34 EXAMPLE OF INSTALLATION OF SPDs AT OR NEAR ORIGIN OF INSTALLATION

11.7.4.6 For small residential buildings, power line SPD at the mains incoming panel will enhance the life of electronic equipment, such as TV, music system, refrigerators, LED lights, etc.

11.7.4.7 For large buildings, power line SPD is required at incoming panel as well as for sub distribution panels based on the LPZ principle {*see* accepted standard [D-2(74)]}.

11.7.4.8 For industrial and commercial buildings, critical and sensitive loads such as drives, PLC's, automation panels, etc, require protection with SPD in addition to SPD at incoming power panels and sub distribution boards. SPDs shall be selected to meet the requirements of relevant LPZs.

11.7.4.9 Lifts, escalators, moving walks and fire panels shall be protected with SPD in control panels. All electrical and control panels related to safety and security of building shall be protected with appropriate SPDs.

11.7.4.10 SPDs should be installed for outdoor equipment such as CCTV cameras, LED street lights, weighbridges, firefighting systems, roof top solar PV installations, etc. This will ensure availability of the vital services provided by these equipment as and when required.

11.7.4.11 Failure of equipment and chance of fire in electrical installations are more for buildings near tall structures (for example, telecom tower). These buildings should be protected with SPD at power incoming and ring earthing to avoid fire and equipment failure.

11.7.4.12 All SPDs should have status indication to show their healthy state for discharging the lightning current. The possibility of failure of L-N as well as N-PE connected SPD cannot be ignored.

11.7.4.13 The SPD shall be installed at the entrance to ensure perfect bonding to the ground at the time of lightning {*see* good practice [D-2(11)] and accepted standard [D-2(74)]}. The let through energy of the protection system shall be less than the energy that equipment can withstand. As per accepted standard [D-2(74)], the energy coordination method is the best method to ensure the protection of the equipment. The let through energy details of the SPD shall be provided by manufacturer.

11.7.4.14 Maximum continuous operating voltage of the SPD (U_c) should not be less than 1.1 × U_{nominal} = 1.1 × 230 = 253 V; temporary overvoltage (TOV) withstand values shall be as per accepted standard [D-2(81)].

11.7.4.15 Low-voltage SPDs for connection to low-voltage power systems shall be conforming to the accepted standard [D-2(81)].

11.8 Average Number of Thunderstorm Days

For the purpose of risk assessment, annual thunderstorm days in various places are provided in the table below read with Fig. 35.

BASED UPON SURVEY OF INDIA POLITICAL MAP PRINTED IN 2002.

THE TERRITORIAL WATERS OF INDIA EXTEND INTO THE SEA TO A DISTANCE OF TWELVE NAUTICAL MILES MEASURED FROM THE APPROPRIATE BASELINE.

THE INTERSTATE BOUNDARIES BETWEEN ARUNACHAL PRADESH, ASSAM AND MEGHALAYA SHOWN ON THIS MAP ARE AS INTERPRETED FROM THE NORTH-EASTERN AREAS (REORGANIZATION) ACT, 1971, BUT HAVE YET TO BE VERIFIED.

THE EXTERNAL BOUNDARIES AND COASTLINES OF INDIA AGREE WITH THE RECORD/MASTER COPY CERTIFIED BY SURVEY OF INDIA.

THE RESPONSIBILITY FOR THE CORRECTNESS OF INTERNAL DETAILS REST WITH THE PUBLISHER.

12 ELECTRICAL INSTALLATIONS FOR CONSTRUCTION AND DEMOLITION SITES

12.1 General

12.1.1 Electrical hazards are a major cause of serious injury and even death in construction sites. Accidents also cause loss of productivity and destroy the morale of workers. The need to use electricity and electrical/electronic equipment has been constantly increasing. Without these gadgets productivity and quality of work will suffer. Therefore, the use of electricity and the use of gadgets has to increase. Such increase requires a proper electrical distribution system in the work site.

12.1.2 To ensure continuous supply of power during the construction activity and maintain productivity, site security, etc the city power supply may be required to be supplemented by on-site standby power generation. Some gadgets require continuity of power supply without interruption, thereby requiring UPS systems. In a typical large construction site there may be a large temporary distribution network combined with more than one source of electricity, which can make the system quite complex from the safety point of view.

12.1.3 Problem may also arise in case of lack of required training to workers in the safe use of the tools and equipment that they are required to handle in a system with multiple sources of power supply. In case of use of imported equipment which may be manufactured to their own standards, problems may arise, such as, during connection and inter-connection of equipment and tools and mismatch of plugs and sockets. Appropriate action is to be taken by employing qualified/experienced electrical engineer.

12.1.4 Practical guidance to employers, designers, manufacturers, importers, suppliers (including hirers), electrical contractors and electricians on eliminating or reducing the risk of electrocution and electric shock to any person is necessary.

12.1.5 Even though awareness exist about good practices, the same may be compromised at times in the name of speed or economy or due to ignorance and neglect. The materials, equipment, tools, cables, switchgear used in the temporary installation face far more severe environmental working conditions because of use of discarded switchgear, cables, etc at the construction sites which compounds the risk to workmen from shock and fire. Hence, the laid down Indian Standards for permanent installations, need to be followed during construction and demolition meticulously. The complete installation shall be duly earthed as per *Central Electricity Authority* (*Measures related to safety and Electric Supply*) *Regulations*, 2023, good practice [D-2(11)] and [D-2(1)].

12.2 Installation and Removal of Construction Wiring

All construction wiring work shall be installed by an appropriately registered electrical contractor and by electrical workmen holding license of the appropriate level of competency depending on the voltage, local generation, etc, as provided in *Central Electricity Authority* (*Measures Related to Safety and Electric Supply*) *Regulations*, 2023 and *the Indian Electricity Act*, 2003. The installation should be inspected prior to commissioning and at regular intervals by the Engineer-in-Charge (if one is qualified to inspect electrical installations) or by representative, who should be competent to inspect an installation.

12.3 Provision of Indicating and Recording Instruments and Meters

Measurement is a prerequisite to analyse the performance. Construction site switchboards should have adequate instrumentation (such as, ammeters, PF meters, voltmeters, energy meters, etc) on different branches of the distribution system so that any abnormal condition or overload is noticed. Considering the nature of varying activity in a construction site, frequent visual, and instrument based inspections are necessary as well as keeping record of the same.

12.4 Residual-Current Circuit Breaker (RCCB)/Residual-Current Device (RCD)

The following shall be ensured in the construction and demolition sites:

a) Every electric supply to which electrical plant can be connected should incorporate an RCCB/RCD of appropriate capacity so as to protect persons who may come into contact with the electrical plant against electric shock;

b) The RCCB/RCD(s) should have a rated tripping current not exceeding 30 mA and should have the capacity to carry the load current required by the appliances permitted to be connected in that branch circuit or feeder;

c) Where construction work supply can only be obtained from a permanent wiring socket-outlet, RCCB/RCD should be connected at the socket-outlet;

d) Sub-mains supplying site sheds should incorporate an RCCB/RCD having a rated tripping current not exceeding 100 mA;

e) Every non-portable RCCB/RCD device on the worksite shall be trip tested by the built-in push button test every month, and performance tested for operation before being put into service and thereafter at least once every 12 months. It shall also be subjected to an imbalance of current not less than the rated residual current and shall trip in a time not exceeding 6 s;

f) Every portable RCCB/RCD device on the worksite shall be trip tested by the built-in push button test. The test shall be done prior to use and each day while in use; and it shall be performance tested for operation before being put into service and thereafter at least once every 3 months. It shall also be subjected to an imbalance of current not less than the rated residual current and shall trip in a time not exceeding 6 s;

g) Results of RCCB/RCD tests shall be recorded and kept on site or made available for audit and kept for a minimum period of 5 years or till the completion and handing over of the project, whichever is less [excluding the daily push button test for portable RCCB/RCD(s)];

h) Portable RCCB/RCD(s) when tested shall be fitted with a durable, non-reusable, non-metallic tag. The tag shall include the following information:

   1) The name of the person or company who performed the tests; and

   2) The test or retest date.

   The recommended colour coding for tags on tested RCCB/RCD, which is prescribed below should be indicated by its colour representing the period when the test was performed:

January to March	:	Red
April to June	:	Green
July to September	:	Blue
October to December	:	Yellow

j) Portable generators should be fitted with RCDs having a rated tripping current not exceeding 30 mA; and

k) Personal hoists used on construction sites shall be supplied from a separate final sub-circuit originating from the main switchboard; and be suitably identified by marking this supply on the RCD/MCB feeding it.

12.5 Temporary Supply Switchboards

All temporary supply switchboards used on building, construction and demolition sites shall be of robust construction and either securely attached to a pole, post wall or other structure which may be of stable freestanding design and:

a) where installed in outdoor locations, should be constructed and maintained to IP23 (or higher) rating so that safe operation is not affected by the weather;

b) switchboards should incorporate the support and elevation of cables and flexible extension cords;

c) switchboard enclosures shall be provided with an insulated or covered tie-bar or similar arrangement for the anchorage of the cables or flexible cords in order to prevent strain and mechanical damage at the termination of the cables or cords;

d) switchboards should be provided with a door and locking facility. The doors should be designed and attached in a manner that will not damage any flexible cord connected to the board and should protect the switches from mechanical damage;

e) the door should be provided with signs (in English, Hindi and at least one local language) stating, 'KEEP CLOSED – LEADS THROUGH BOTTOM';

f) switchboards should have an insulated slot (with edges suitably shaped or covered with plastic or rubber trims to avoid damaging the cable insulation/sheath) at the bottom for the passage of leads;

g) switchboards should be attached to a permanent wall or suitable portable or temporary structure in an elevated position suitable for easy access and having least interference with the activity in the area;

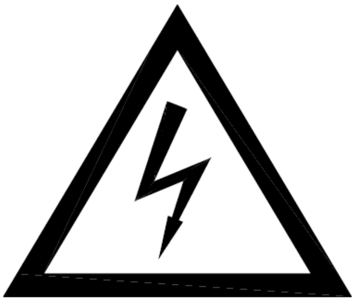
h) if the floor in that area is likely to be wet, additional precautions are necessary and an insulated platform should preferably be provided for access to operation of switches. Personal protective equipment such as helmet, electrician gloves, etc, should be available, placed near the switchboard, as an alternative;

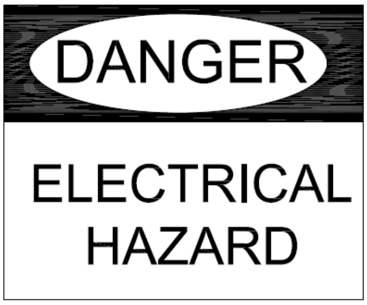
j) a clearance of at least 1.2 m should be maintained in front of all switchboards;

k) the contractor or nominated persons should ensure that all power circuits are isolated or made inaccessible so as to eliminate the risk of fire, electric shock or other injury to persons after completion of the daily work;

m) switchboards shall be legibly and indelibly marked with a set of numbers or letters or both which uniquely identify the switchboard from others on a site;

switchboards shall be marked to indicate the presence of live parts in accordance with symbols such as the following drawing:





p) chart indicating first aid measures for electric shock management should be placed near the switchboard;

q) ‘Lock Out and Tag Out’ procedures as adopted should be displayed;

r) the switchboard should be lighted properly to ensure its identification and safe working; and

s) all switchboards should have their identification names (or/and numbers) so that any communication/ instructions about them are unambiguous.

12.6 Cables Used in Worksite Installations

12.6.1 Worksite poses a number of hazards to the cables. The conditions are severe compared to those in permanent installations. Cables face dust, moisture, abrasives and even impact unlike those in permanent installations. Extra care should be taken to frequently inspect the cables and discard cables which show signs of damage as a damaged insulation combined with moisture can be dangerous.

12.6.2 Cables are likely to be run over by vehicles. Suitable protection is required by a steel pipe or hume pipe or steel plate, whichever is appropriate. Dragging of cables damages their sheath/insulation and may also cut a few strands of the conductor due to stretching, effectively reducing the current carrying capacity. Hence suitable care should be taken while laying the cables.

12.6.3 Overhead installation of cables is a common practice. Such installations should use a GI wire to carry the weight of the cable without causing the stretching of the cable. The carrier GI wire should be earthed. Unarmoured cables shall not be installed on metallic roofs or similar structures unless suitably protected against mechanical damage.

Overhead wiring should be positioned to avoid crossing roadways or accessways where cranes, high loads, or heavy machinery may travel. Where it is not possible to avoid accessways an effective means shall be provided to minimize the risk of the vehicular contact with the aerial wiring system. This condition may be satisfied by the placement of flagged catenary wires or cables of suitable material across the accessway, 6 m on either side of the overhead wiring and 0.6 m below the lowest point of the overhead electrical cables or lower.

All aerial conductors installed on construction and demolition sites shall be insulated. Cables supported by means of a catenary shall be stranded or shall be flexible cables affording double insulation or the equivalent of double insulation. Construction wiring (including switchboards) shall be visually inspected at intervals not exceeding 6 weeks.

12.7 Electrical Plant in Service Testing

Electrical plant shall be inspected and tested in accordance with the following:

a) Movable electrical plant that is hand held or portable during operation or moved between operations and is subject to damage or harsh environment shall be examined and tested every 3 months;

b) All other electrical plant used for construction purposes shall be inspected and tested at intervals not exceeding 6 months;

c) When any equipment inspected or tested in accordance with (a) and (b) is found to be unsatisfactory, it shall be withdrawn from service immediately and have a label attached to it, ‘Warning against Further Use’. Electrical plant found to be unsatisfactory shall not be returned to service until it has been repaired and retested;

d) The inspection and testing specified should be carried out by an authorized/qualified person; and

e) The results of the inspection of electrical plant should be recorded and kept on site or made available for inspection by authorities. Information recorded shall include:

    1) the name of the person or company who performed the tests;

    2) the test or retest date; and

    3) identification of faulty equipment and action taken to repair or remove it from use.

12.8 Lighting

Following in respect of lighting shall be ensured in construction and demolition sites:

a) *Access lighting* — Adequate artificial lighting should be installed to illuminate the work area if there is insufficient natural lighting. Lamps in luminaires shall be protected against mechanical damage. Luminaires installed as part of the permanent electrical installation in site accommodation, may not require further mechanical protection;

   Sufficient battery powered lighting shall be installed in stairways and passageways to allow safe access and exit from the area if there is insufficient natural lighting. If there is a loss of supply to the normal lighting in the area, it should be ensured that battery powered lighting has sufficient capacity to operate for one hour to allow persons to exit the building safely.

   Temporary wiring supplying lighting circuits should be connected to the designated lighting circuits of the switchboard.

b) *Task lighting* — Portable luminaires shall be provided with the appropriate ingress protection (IP) rating. Task lighting in many construction site may have to move continuously in steps as the work progresses. The lighting system should also be shifted in suitable steps instead of simply extending the cables without any consideration for safety. Hand held additional lights, if any, should be taken from a socket protected by a RCCB/RCD of 30 mA setting just like hand held tools;

c) *Lift and service shaft lighting* — Lift and service shaft lighting may have either construction wiring or permanent wiring. Fluorescent lighting should be used. The lights should be located on the floor above or below the work area. It shall be ensured that the emergency lighting has sufficient battery capacity to operate for a minimum of 1 h if there is a loss of supply to the normal lighting in the area;

d) *Lighting in means of egress* — Sufficient battery powered lighting shall be installed in stairways and passageways to allow safe access and exit from the area if there is insufficient natural lighting. If there is a loss of supply to the normal lighting in the area it shall be ensured that battery powered lighting has sufficient capacity to operate for 1 hr to allow persons to exit the building safely; and

e) *Illumination of signs and warning boards* — Sufficient lighting should be available to illuminate the sign boards and warning boards. These lights may also be a part of the lighting set for means of egress.

12.9 Transportable Construction Buildings (Site Sheds)

Electrical installations to transportable construction buildings shall comply with the following:

a) If supply is by means of a flexible cord, the same shall not be taken from one transportable building to another transportable building.

b) The flexible cord supplying a transportable building should not be more than 15 m in length.

c) Each amenity in the building shall be connected/supplied by a flexible cord to a final sub-circuit protected by an RCCB/RCD device with a rated tripping current not exceeding 30 mA; these flexible cords should be protected from mechanical damage and power outlets in site sheds should be used to supply power to the equipment and lighting within the shed only.

d) Socket-outlets installed on the outside of transportable building shall be used only to supply power to the following:

   1) Electrical equipment and lighting immediately adjacent to those transportable buildings.

   2) Other transportable buildings when the socket-outlet is part of an interconnecting system and the flexible cord supplying those transportable buildings has a maximum length of 15 m.

12.10 Lock-Out and Tag-Out Practices

Whenever an electrician is to work on a branch feeder from the switchboard it becomes necessary that the switch feeding the feeder on which work is done is to be switched-off and should be kept switched-off till the same electrician decides to switch on after completion of work either for testing or for putting the section back into service. To ensure that during the period an electrician is working on a feeder or the equipment it feeds, the practice is to put a ‘tag’ on the concerned switch. The tag will carry details about which authorized worker has put the tag and when and who is authorized to remove it. This is a very critical operating practice for maintenance of the electrical system and following it is of particular importance in the case of temporary installations, where such requirements arise more often than in permanent installations.

Lock-out procedure shall be similar to the above but the difference is that the relevant switch is kept locked in off position and the key is kept by the person or the team leader who will be working on the feeder. The system should also maintain a register where the activities of this nature and the details of action (repair, transfer of the end equipment to a new location, addition of a new appliance on the feeder, etc) are recorded.

12.11 Standard Operating and Maintenance Practices in Sites with More Than One Source of Electricity

12.11.1 In medium and large construction sites it is common to use local generation of electricity by a diesel generating set. The reasons may be lack of dependable local/city distribution system for continuous power supply, high cost of temporary connection charges, restrictions on use of certain equipment like welding transformers on temporary connection, etc. Apart from DG sets for power requirement of site construction equipment, there may be office equipment with computers and site laboratory equipment which require un-interruptible power supply. Shock hazards depend on the voltage of the system and the consequent current flow through the body. As such shock risk associated with all these sources is the same.
